# INDEX TO VOLUME LXXVII.

	PAGE.		PAGE.
<b>A</b> BLOTT, E. G. and Pingree, H. A. The restoration of the normal balance of the foot ..... 875, 976, 1070		<b>Allopeia</b> , lotions and pomade for ..... 119	
Abdominal gunshot wound of ..... 186, 892		posttyphoid, treatment of ..... 948	
punctured wound of ..... 595		Alumni reunions in Chicago ..... 1157	
Abdominal contusions, avulsion of mesen- tery in ..... 661		Alumina in children ..... 1124	
incision ..... 473		pernicious, blood depletion ..... 800	
section, enema after ..... 660		of pregnancy ..... 1264	
for trauma of uterus ..... 86		splenic, splenectomy in treatment of ..... 1125	
surgery, postoperative complications in tenderness, significance of ..... 474, 912		Anaesthesia, accidents during ..... 782	
tumors, pseudomalignant ..... 514		analytical study of six hundred cases of after ..... 1148	
Abortion and labor, febrile conditions following ..... 300		by nitrous oxide, nitrous oxide and oxy- gen, nitrous oxide and ether, chloro- form and oxygen, and ether adminis- tered per rectum ..... 196	
Abscess and hematoma, septal, treatment of ..... 561		chloroform, studies concerning ..... 30	
appendicular ..... 39		ether ..... 497	
cellular, symptoms of ..... 657		ethyl chloride for ..... 963	
cerebral, with masked symptoms ..... 691		fatalities ..... 472	
of frontal lobe of traumatic origin ..... 891		general, clinical study of ..... 963	
of kidney after gonorrhoea ..... 1169		with sequestration of a portion of the circulation ..... 263	
perinephritic, following parturition ..... 87		lumbar ..... 374, 1215	
subphrenic, a complication of appendi- citis ..... 513		scopolamine morphine in gynaecology ..... 421	
surgical abscess ..... 515		surgery before the days of ..... 963	
tropical, of liver ..... 275		Anaesthetics, deaths under ..... 705	
Abscesses, acute, treatment of ..... 1120		Analgesia, intraspinal ..... 868	
use of thymol camphor in treatment of ..... 360		spinal, clinical experiences with ..... 371	
Accidents, dependency arising from ..... 121		Anaphylaxis and anaphylaxis ..... 726	
with vomiting ..... 1214		relation of, to the toxemia of pregnancy ..... 1222	
medicolegal considerations of ..... 129		Anastomosis, arterial, and transfusion ..... 806	
relation of, to nervous diseases and psychoses ..... 129		Anatomy and physiology among the Chi- nese ..... 363	
Acetonauria, postoperative, significance of ..... 224		study, a new method of ..... 993	
with vomiting ..... 183		Anders, James M. A brief critical review of a year's progress in tropical medi- cine ..... 815	
Acid glycuronic, in conditions of dimini- shed oxidation ..... 244		Aneurysm of aorta, importance of early detection of ..... 806	
hydrochloric, in gout ..... 1045		of ascending aorta ..... 660	
in pyloric insufficiency with diarrhoea ..... 946		Angina, Ludwig's ..... 566	
uneven distribution of, in the gastro- intestinal contents ..... 177		pectoris, ligation of coronary arteries in treatment of ..... 955	
iodic, antiseptic value of ..... 107		Angulation of the sigmoid ..... 832	
iodoformic, in treatment of phthisis ..... 272		Angulations of sigmoid and colon ..... 479	
intoxication ..... 755		Anilines, poisoning by ..... 123	
lactic, for alopecia ..... 648		Animal therapy, application upon the op- sonic index in tuberculosis ..... 587	
picric, for plantar hyperidrosis ..... 27		Antaphrodisiacs, formulas for ..... 457	
pyroglycerous, for arthritis deformans ..... 408		Antibody in experimental practice ..... 1056	
salicylic, excretion of ..... 230		true conception of ..... 869	
method of administering ..... 551		Antimony as a hepatic stimulant ..... 662	
sulphurous, in Cantharidia dried fruit ..... 911		Antisepsis ..... 662	
tannic, in treatment of dermatitis vene- rata ..... 458		value of, in bronchial catarrh ..... 551	
uric, formation, elimination, and effect on general system of ..... 246		Antisepic, intestinal, for children ..... 948	
Acidoses, classification of ..... 936		Antisepsis in osteomalacia ..... 1261	
Acne, applications for ..... 119		Antistoxic function and albumin ..... 230	
Adams-Stokes syndrome without blocking ..... 132		Antitoxine, diphtheria, refined and con- centrated by Gibson's method, results obtained from administration of ..... 1242	
Adenectomy during middle ear disease ..... 375		uricaria after administration of ..... 1165	
Adenoid patients, postoperative treatment of ..... 912		tetanus, the American unit of ..... 1048	
Adenoids and tonsils ..... 271		Antityphoid inoculation ..... 1259	
removal of ..... 293		Antrum of Highmore, carcinoma of ..... 417	
Adenomyoma of uterus ..... 128		Anus, fissure of, suppository for ..... 943	
Adhesions, perigastric, fibrolysin treatment of ..... 132		of abscess, as a complication of ..... 806	
Adiposa tuberosa simplex ..... 613		spontaneous rupture of ..... 181	
Adrenalin in eczema ..... 1150		traumatic insufficiency of ..... 911	
Aerotherapy in toxæmias of childhood ..... 809		Aortic incompetence in later life ..... 708	
Agassiz, A. S. Treatment of post partum hemorrhage ..... 263		regurgitation and floating liver ..... 400	
Air, compressed, for dilating Eustachian tube ..... 331		Aphasia, relation of auditory centre to ..... 125	
house, a simple ..... 1081		Aphrodisiacs, formulas for ..... 457	
passages, upper, inhalations of saponin in ..... 612		Appendicectomy, technique of ..... 1010	
Alaska, medical notes on ..... 1052		Appendicitis, association of, with other dis- eases in female pelvis ..... 521	
Albee, Fred H. Osteomyelitis ..... 1077		due to presence of oxyuris vermicularis ..... 36	
Albumin, smallest necessary supply of ..... 84		early operation in ..... 469	
Albuminuria ..... 230		in children ..... 39	
and itch, connection between ..... 459		one hundred consecutive operations for ..... 320	
calcium chloride in ..... 457		reflex troubles of the pulse in ..... 228	
orthotic, in children ..... 321		relation of, to gynaecological pelvic dis- eases ..... 753	
Alcohol, effect of, upon secretions ..... 569		subphrenic abscess as a complication of ..... 691	
infectious, facial, ophthalia ..... 178		surgical treatment of ..... 708	
Alcoholic stupor, diagnosis of ..... 154		symptoms of ..... 708	
postdelirious ..... 154		traumatic ..... 660	
Alcoholism and inebriety, literature of ..... 620		with acute enteritis ..... 18	
chronic, treatment of ..... 632		x rays in diagnosis of ..... 1166	
Alger, E. L. To what extent can the graine amenable to treatment of the eyes? ..... 1082		Appendix, abscess of ..... 39	
Alimentary intoxication, treatment of ..... 702		carcinoma of ..... 1057	
Alkaline earths, hemastatic action of ..... 228		of abscess, as a complication of ..... 185	
Allen, A. H. Notes on dengue ..... 358		hernia, involution of ..... 1050	
Allopeia, lactic acid for ..... 648		vermiform, diverticulum ..... 1050	
		metaplasia of ..... 1050	
		Apraxia of cephalic muscles ..... 1052	
		Aran-Duchenne type of muscular atrophy ..... 1056	
		Arc light treatment of skin diseases ..... 869	
		Arhovin in treatment of gonorrhoea ..... 105	
		Armstrong, Alfred W. The causes of ap- pendicitis ..... 6	
		Armstrong, Samuel T. The need of care for the convalescent from the hospital standpoint ..... 43	
		Army Medical Bill ..... 126	
		Department examinations ..... 126	
		necessity of important changes in or- ganization of ..... 33	
		rank and pay of officers of ..... 95	
		officers, increased pay for ..... 109	
		reserve corps of ..... 124	
		service of ..... 80	
		tension, high, causes and treatment of ..... 30	
		Arteries, coronary, ligation of, in treatment of angina pectoris ..... 95	
		Arteriosclerosis ..... 17	
		lactic lemonade for ..... 96	
		local ..... 42	
		nervous manifestations of ..... 95	
		relation of age to ..... 8	
		studies on, with special reference to the radial artery ..... 27	
		Arteritis obliterans ..... 75	
		peripheric rheumatismal ..... 121	
		Arthritis deformans of the hip ..... 40	
		pyroglycerous acid for ..... 3	
		intoxic, strain as a causative factor in rheumatoid ..... 37	
		Arthrodesis and tendon transfer in paraly- tic club feet ..... 75	
		active union transplantation ..... 66	
		value of ..... 122	
		Ascari, treatment of ..... 4	
		Ascites associated with hepatic cirrhosis ..... 95	
		Ashford, Bailey K. Puerto Rico as a field for research in tropical medi- cine ..... 122	
		Aspiration diseases, artificial pneumothorax in ..... 8	
		Association of American Physicians ..... 95	
		of Tuberculosis, the City of New York ..... 91	
		State Charities Aid ..... 28	
		Asthma, bronchial, mixture for ..... 45	
		Asthma, cardiac, injections of serum in treatment of ..... 121	
		powders for inhalation in ..... 64	
		spray for attacks of ..... 125	
		typhic ..... 70	
		Ataxo-laryngeal manifestations ..... 121	
		Atresia, acquired, of common duct, due to gallstone ..... 32	
		Autoinfection, bronchointestinal, in the new born ..... 61	
		Axilla and rectum, importance of differ- ence in temperatures of ..... 66	
		<b>B</b> ACHMANN, Robert A. Treatment of feverishness ..... 102	
		Bacilli, influenza, in the bronchi ..... 51	
		paratyphic ..... 37	
		tubercle, essential identity of ..... 22	
		Bacillus in childhood ..... 22	
		Bacillus coli communis, distinction of, from allied species in water ..... 96	
		Friedlander's, a cause of pneumonia ..... 101	
		Bacteria as incitants of malignant endo- carditis ..... 3	
		nonpathogenic, disinfection of body cavities by ..... 121	
		pathogenic forms of, opsonins as a means of distinction and identification of ..... 61	
		Bacterial disease, specific vaccines in treat- ment of ..... 7	
		vaccines and curative sera ..... 4	
		Bagg, L. W. Treatment of fracture of patella ..... 86	
		Baldwin, R. Review of the literature considerations and experimental work relative to opsonins ..... 12	
		Ballag, John. Acute syphilitic nephritis ..... 12	
		Ballin, Milton J. A larynx knife and silver metal carrier ..... 96	
		The removal of adenoids ..... 21	
		Baltimore milk supply, chemical examina- tion and inspection of ..... 1	
		Barber, L. F. Indications for water in childhood ..... 21	
		Barrier, L. F. Treatment of fracture of patella ..... 8	
		Battlefield, illumination of, for search of wounded ..... 47	

	PAGE.
lates, W. M. Metchnikoff's sour milk.....	330
ath for urticaria.....	1044
tub, treatment of cystitis.....	45
lath, mud, influence of, upon organs of circulation.....	324
leardley, John Gillespie. A unique case of urticaria.....	162
eck, Carl. Urethral plastic operations.....	287
lecker, Henry C. Treatment of sun- stroke.....	1244
ledosors, application for prevention of.....	694
lenedey, L. L. The ophthalmic tubercu- lin test.....	1233
lenzi vapor, acute poisoning by.....	39
eribero, etiology of.....	281
ernard, William E. Mercury and tubercu- losis.....	1236
erlin clinic in Berlin, observations made at ierhoff, Frederic. Hysterical retention of urine.....	70 163
The abortive treatment of gonorrhea in the female.....	60
The newer methods of examining the bladder.....	588
The palliative treatment of prostatic hy- pertrophy.....	731
The word "palliative".....	1062
ier's hyperemia in inflammation.....	374
in treatment of metritis.....	374
in tuberculosis of bones and joints.....	470
stasis, action of.....	40
ile changes in infective diseases.....	373
ducts, relation of typhus and paratyphus fevers to.....	1125
blumuria to the blood, relation of uro- bilinuria to.....	1094
illary calculus, treatment of pain from passages, diagnosis, and treatment of in- fection of.....	276
irth rate in New York, an improved.....	602
ismuth subnitrate in diseases of the stomach.....	792
nitrate poisoning.....	89
lackwell, Hugh Burke. A new pliable submucous elevator.....	1266
ladder and urethra, overstretching of.....	711
in tables.....	1038
newer methods of examining.....	588, 711
prolapse of, surgical treatment of.....	1264
treatment of, after suprapubic cystostomy for stone.....	88
tumors of, transperitoneal removal of.....	86
laim, Alexander W. A clinical study of general anesthesia.....	888
leading, etiology, significance of.....	803
lepharoplasty by means of pedicled flap taken from the neck.....	613
lindness, night.....	571
sudden, and its various causes.....	771
lood, red, relation of cobra poison to.....	1125
clot, destruction of.....	612
modified, in mastoid surgery.....	1144
coagulability in the puerperal state.....	228
coagulation.....	1004
clinical aspects of.....	232
condition of, in poisoning by arsenic.....	153
conservatism of neurotic individuals.....	593
typhoid fever.....	1163
negative results in.....	1222
depletion in pernicious anemia.....	963
human, antiferment action of.....	300
influence of electrical stimulus upon dis- tribution of.....	324
intracranial extravasations of, in newly born.....	757
oplastic, bactericidal and hemolytic ef- ficiency of material in.....	660
optonic index of, accuracy of method of determining.....	1217
destruction of.....	707
pressure, effects of hydrastis and its al- kaloids on.....	79
graphic registration of.....	612
high, the organic factor in.....	320
in the practice of medicine.....	754
observations in eclampsia.....	958
reactions of inflammation.....	41
serum, hemolytic reaction in malignant tumors.....	1168
in the guinea pig.....	1168
testes, foreign, in larynx.....	655
in upper jaw the cause of conjunctivi- tis.....	85
swallowing of.....	231
ody cities, disinfection of by nonpatho- genic bacteria.....	1231
chemical control of.....	559
foreign, in left bronchus.....	181
in the nose.....	57
old, H. J. Progress in gynecology from a clinical viewpoint.....	85
olus treatment of diarrhoea.....	39
omb, a normal saline.....	1203
one disease, tuberculous.....	310

Bone tumors, conservative operations on.....	271
Bones, long, fractures of.....	909, 962
malunion of.....	860

## BOOK NOTICES:

Abel's Laboratory Handbook of Bacteri- ology.....	571
Adamson, H. G. Skin Affections in Childhood.....	667
Aikens, Charlotte A. Hospital Training School Methods and the Head Nurse.....	581
Anders, James.....	272
Annales de la Société royale des sciences médicales et naturelles de Bruxelles.....	93
Anziolotti, Prof. dott. Giulio. Sul pro- cesso di riparazione delle perdite di sostanza nelle cartilagini e pericon- dro.....	1268
Avellis, Dr. med. Georg. Verhandlungen der deutschen laryngologischen Gesell- schaft.....	966
Babcock, Robert H. Diseases of the Lungs.....	966
Ballengier, Louis. Lincolna. Diseases of the Nose, Throat, and Ear.....	1128
Bandler, Dr. Lehrbuch der spezi- fischen Diagnostik und Therapie der Tuberkulose.....	716
Barnhill, John F. and Walter Ernest de Wolfe. Principles and Practices of Modern Otology.....	44
Barrus, Clara. Nursing the Insane.....	1015
Bartley, Elias. A Clinical Chemistry.....	332
logics and Chemical Chemistry.....	332
Baruch, Simon. The Principles and Practice of Hydrotherapy.....	1222
Barwell, Harold. Diseases of.....	1282
La Runcie.....	282
Baumann, Frederick. Gonorrhoea.....	1128
Baumgarten, Dr. med. P. von. Jahres- bericht über die Fortschritte in der Lehre von den pathogenen Micro- organismen umfassend Bakterien, Pilze, und Protozoen.....	763
Bechterew, Dr. W. v. Die Funktionen der Nervencentra.....	918
Beers, C. W. A. Mind that Found Itself.....	601
Bericht über den XIV internationalen Kongress für Hygiene und Demog- raphie, Berlin.....	1175
Bezold, Dr. Textbook of Otolaryn- gology for Physicians and Students.....	619
Blair, Virlyray Papin. Laboratory Guide for the Modelling of the Human Bones in Clay.....	571
lewan, Dr. Die Praxis der Haut- krankheiten.....	1128
Blyth, Alexander Wynter. Poisons.....	428

starch in	1011	Kaufman, Albert. Treatment of stroke	1247	Mills, Charles K. Neurological hospitals	91
use of fat free milk in	607	Keating, Emmet. The early diagnosis of pulmonary tuberculosis	528	Packard, Horace. Recovery from cancer	232
life, concerning the first week of	655	Kensett, W. T. The pangle phall	1085	Piffard, Henry G. Microorganisms or virchet	82
morbid in nature	655	Kenner, Carl R. The treatment of infantile paralysis	1189	Rorcher, W. Peyre. Compressed air for dilating the Eustachian tube	331
Infants, wasted, aetiological conditions in	1209	Keratitis, neoplastic, bacteriogenic of	227	Rose, A. Malaria in Greece	966
Infection, extragenital	23	Kidney, disease of, after gonorrhoea	1163	The treatment of prostatic hypertrophy	916
modes of, in tuberculosis	1209	decapsulation of, in eclampsia	133	Smith, A. C. The aetiology of beriberi	281
with trypanosoma of equine syphilis, or gonorrhoea	1167	hemorrhage into fatty capsule of	84	Spear, Edmund D. Acute poliomyelitis	201
Infections, acute, the kidney in	1066	in acute infections	1030	Taylor, J. Madison. Manual thet	68
air borne	1066	lesions in infants	1218	Leuchemia, acute lymphatic, spirocheta in treatment of, by the x ray	864
alimentary, and paratyphus	373	movable	40	Leucocyte examination in suppurative conditions arising from middle ear infection	345
in childhood, pyogenic	892	rupture of	1012	Leucocytes, bactericidal and hemolytic efficiency of material in	660
lymphatic and portal, following appendicitis	522	sarcoma of	1012	Leucorrhoea, douche for	170
of biliary passages, diagnosis and treatment of	276	solitary	962	Libraries, great medical	901
stomach, acute, treatment of	1058	tuberculosis of, treated with x rays	182	medical, for small centres	810
Infectious diseases, intravenous injection in	1045	Kidneys, action of purgatin on	1218	Life and relapsing fever	36
Inflammation, blood reactions of	41	liver in disease of	659	Licky, Iva M. Treatment of post partum hemorrhage	212
subcephalic	220	transplantation of	565	Lids and orbital tissue, repair of	735
Influenza bilious	517	Kinch, Charles A. Teaching of dermatology in medical schools	309	Lids, first week of	371
of throat, and larynx	18	Kirby, Frank B. Treatment of gallstone colic	504	Ligament, sensitive short uterosacral, treatment of	185
cerebral	187	Kivlin, C. F. Varicose veins	103	Ligaments, round, intramural transplantation of	118
Injuries and the previous condition	795	Klingmann, Theophil. Spontaneous rupture of the heart	198	Silk use of in infantile paralysis	118
Inoculation, antityphoid, in British Army	1259	Klotz, J. E. A catechism for physicians	714	Sutures and sutures, buried	525
after care of	383	Diagnosis of the localities	714	Light, arc, in treatment of skin diseases	860
care	623	Knap, Mark I. About Dr. Palier's article on pyloric insufficiency	1062	Lighburn, Richard. Treatment of gallstones	944
development of modern care and treatment of what we have not done for	623	Knee joint injuries	179	Lilienthal, Howard. Suprapubic prostatectomy in two stages	134
women	182	relaxed	135, 1050	Ligaments in orthodontic	1160
Insanity, potassium iodide in	19	Knoel, S. Adolphus. The aetiology, prophylaxis, and treatment of the social ill	819	Lister's formula for chronic catgut	458
Insomnia	419	Knoel, surgical, art of tying	1165	Liver and gallbladder, surgery of	567
Inspection of schools, medical, with trained nurses	637	Knot, R. R. A dinner to	748	and spleen in relation to hemolytic icterus	
Insufficiently recognized, diagnosis of, pyloric, Dr. Palier's article on	662	New York's tribute to	746	atropin of	1160
with diarrhea	636	Kolle-Wassermann's meningococcus serum in meningitis	220	catgut of	458
traumatic, of aorta	911	Korke, R. R. The management of self limited disease	1010	chylous, case of	1162
Interferon, lotions for	170	Kosher, Morris. Malnutrition	985	chylous, case of	1162
Intertrigo, aetiology for children	948	Kraske's operation, technique of	181	chylous, case of	1162
Intestine, high occlusion of	184	Kummerfeldt's lotion for acne	119	chylous, case of	1162
Intoxication, alcohol, for	755	LABOR and abortion, febrile conditions after	300	chylous, case of	1162
alcoholic, draught for	202	delayed	161	chylous, case of	1162
alimentary	202	premature, induction of	160	chylous, case of	1162
enterogenous, indican reaction as evidence of	806	Laboratories, county, and their uses	810	chylous, case of	1162
intoxication	806	Laboratory, clinical, of general practice	639	chylous, case of	1162
intoxication, appendicitis, diagnosis of	655	Lactinoid milk in infant feeding	1042	chylous, case of	1162
bolus, antiseptic value of	216	Lactinoid milk in infant feeding	1042	chylous, case of	1162
bolus and guaiacum injection for tuberculous	310	Lactinoid milk in infant feeding	1042	chylous, case of	1162
bolus	310	Lactinoid milk in infant feeding	1042	chylous, case of	1162
application of, in the dark	310	Lactinoid milk in infant feeding	1042	chylous, case of	1162
formic acid solution in phthisis	116	Lactinoid milk in infant feeding	1042	chylous, case of	1162
in the treatment of ulcers	216	Lactinoid milk in infant feeding	1042	chylous, case of	1162
bolus, fluid, medicinal uses of	310	Lactinoid milk in infant feeding	1042	chylous, case of	1162
bolus, rational treatment of	310	Lactinoid milk in infant feeding	1042	chylous, case of	1162
bolus	310	Lactinoid milk in infant feeding	1042	chylous, case of	1162
Iron, comparative therapeutical value of the compounds of	68, 1130	Lactinoid milk in infant feeding	1042	chylous, case of	1162
in chlorosis	554	Lactinoid milk in infant feeding	1042	chylous, case of	1162
stains on the teeth, application for	111	Lactinoid milk in infant feeding	1042	chylous, case of	1162
formic acid solution in phthisis	116	Lactinoid milk in infant feeding	1042	chylous, case of	1162
in the treatment of ulcers	216	Lactinoid milk in infant feeding	1042	chylous, case of	1162
bolus, fluid, medicinal uses of	310	Lactinoid milk in infant feeding	1042	chylous, case of	1162
bolus, rational treatment of	310	Lactinoid milk in infant feeding	1042	chylous, case of	1162
bolus	310	Lactinoid milk in infant feeding	1042	chylous, case of	1162
Iron, comparative therapeutical value of the compounds of	68, 1130	Lactinoid milk in infant feeding	1042	chylous, case of	1162
in chlorosis	554	Lactinoid milk in infant feeding	1042	chylous, case of	1162
stains on the teeth, application for	111	Lactinoid milk in infant feeding	1042	chylous, case of	1162
formic acid solution in phthisis	116	Lactinoid milk in infant feeding	1042	chylous, case of	1162
in the treatment of ulcers	216	Lactinoid milk in infant feeding	1042	chylous, case of	1162
bolus, fluid, medicinal uses of	310	Lactinoid milk in infant feeding	1042	chylous, case of	1162
bolus, rational treatment of	310	Lactinoid milk in infant feeding	1042	chylous, case of	1162
bolus	310	Lactinoid milk in infant feeding	1042	chylous, case of	1162

#### A STUDY OF SOUR MILKS.\*

By HENRY G. PIFFARD, M. D., LL. D.,  
New York.

Many years ago, when Abraham was encamped on the plains of Mamre, three strangers approached and he hastened to welcome them.

They had come to bring him the joyful though unexpected tidings that Sarah, his wife, although well stricken in years, would in due time bear him a son.

Abraham, with hospitable intent, directed his servants to prepare food for the visitors; "and he took curdled milk and (ordinary) milk, and a young ox which he had prepared and set (them) before them—the while he stood under the tree and they ate." Genesis xviii, 8.

Many years later, when Israel had become a mighty but a stiff necked people, Moses upbraided them for their sins and called their attention to the many bounties the good Lord had showered upon his chosen people, and among these were: "Curdled milk of cows and the milk of goats, together with the fat of lambs and rams—animals of Bashan and he-goats with the kidney fat of wheat, and the blood of grapes that thou didst drink as fiery wine." Deuteronomy xxxii, 14.

These passages certainly show that when they were originally written, several hundred years before our present Christian era, sour ("curdled") milk was held in sufficient esteem to be set before honored guests, and by Moses to be accounted one of the good things for which his people should be thankful.

It is further related in sacred history that Abraham, after the death of Sarah, procured another wife and several concubines and lived to be the father of six additional sons by his wife and several by his concubines, dying at the ripe age of 175 years. If these things were the result of a sour milk diet, it is not surprising that the custom flourished in eastern countries.

At all events we know that for many centuries the peoples of eastern Europe, of western and middle Asia, and a part of Africa have looked on sour milk as an essential portion of their daily diet; for various reasons, preferring it as a rule to fresh sweet milk.

In western Europe and in America *buttermilk*<sup>1</sup> has been, with many, a favorite beverage. The present writer's knowledge of and fondness for it extends backward for more than half a century; and for more than twenty-five years I have directed many patients to use it for both dietetic and directly remedial purposes. I must admit that such use of it has been largely empirical, rather than based on any clear notion as to the rationale of its action.

A year or more ago, I read in one of the city journals what purported to be a declaration by the present head of the Health Department to the effect that sour milk was a menace to health and that he would prosecute any one having it in possession and offering it for sale. Later I obtained a *Circular of Information* issued over his name from which I quote the following:

"As bacteria increase in numbers, they gather nourishment from the milk and other substances in which they develop, and, like other higher forms of life, transform what they take into their bodies into useless or poisonous products. They thus both rob the food of its nutritious substances and add others to it which are more or less poisonous. When bacteria grow in living things, whether they be men, animals, or plants, they excite changes in them which we know as disease. The bacteria which grow in dead things cause them to ferment, rot, or putrefy. Thus milk becomes sour through the change of its milk sugar into acid, produced by bacteria."

In view of the antiquity of the use of sour milk: in view of its great prevalence in certain countries, and in view of the researches of Metchnikoff as to the extreme old age attained by habitual users of sour milk, the foregoing statement of the chief sanitary officer of the city is certainly astounding, and especially as that, holding these views, he permits the present extensive sale of sour milk within the limits of his jurisdiction or even allows it to be brought here. As a matter of fact, sour milk under various names is openly dispensed from pint and half pint bottles at nearly every drug store. The large dairy concerns will serve it at your residence for six cents a quart and the smaller milk shops commonly serve it over the counter at three cents a glassful.

The term *sour* as used in this connection covers all milks or parts of milk in which a lactic acid fermentation has been brought about through the action of bacteria or other micro-organisms. Some of the sour milks sold are raw whole milk of which

the cream has been removed, and some are the residue left after the cream has been removed. The latter is known as *buttermilk*. "Buttermilk" from which the butter has been removed—

\*Read at a meeting of the Biological Hygiene Association, December 4, 1907.

The question here presented has been fairly recently discussed by Professor Richard C. Griffith before the annual session of the Biological Society. One differs somewhat from the author's conclusions. In choosing between two conclusions, I prefer to rely on modern scholarship rather than that of the Greek or Roman.

kumyss is a type; others are cooked whole milk, of which zoalak may be taken as an example; others are raw skimmed milks, while others again purport to be sterilized skimmed milk to which living microorganisms of the lactic acid group have been intentionally added.<sup>8</sup> Traces of acetic and succinic acids have been found in milk, but are a negligible factor so far as regards the present inquiry. Butyric acid is not found in reasonably fresh milk, though in very stale milk I have assumed its presence by the odor. It is best known in connection with rancid butter.

In looking for confirmation of the official opinion of the Health Department as to the unwholesomeness of sour milk, I have been able to find but a single author who supports him, which he does in the following words:

"Bacteria when allowed to develop in milk produce fermentation (souring) and render the milk unfit to be used as an article of food, especially for infants."

I am quite ready to grant that certain changes, due to bacterial action, may occur in milk that renders it unwholesome and even actually poisonous. Tyrotoxicon has been found in milk, in cheese, and in stale ice cream and has, on a number of occasions, led not only to serious but fatal illness; but, so far as I am aware, there is absolutely no evidence connecting the ordinary lactacidogenous bacteria with these detrimental changes.

On the contrary, the lactacid bacteria act as wholesome conservators, and so long as they remain in control hinder or inhibit the injurious changes that later may occur in milk. Unfortunately, the energies of these microorganisms become exhausted in time, and a totally different class of bacteria become supreme, rendering the milk alkaline and unquestionably liable to produce serious derangements. The fresh milk of the cow is ordinarily amphoteric, that is it will act on both blue or red-dened litmus. If kept in a warm place for twenty-four hours it will give a distinctly acid reaction only, but if kept for a considerably longer period it may respond to the well known phenol phthalein test.

In support of the position I have taken I will quote the words of a few investigators whose opinions, it appears to me, merit respect:

"The lactic acid microbes produce large quantities of acid and so hinder the multiplication of the organisms of putrefaction. . . . Such facts explain how it is that lactic acid frequently stops some cases of diarrhoea, and why treatment with lactic acid is so useful in maladies associated with putrefaction of the intestinal contents."—Metchnikoff.

"Among the useful bacteria, the place of honor should be reserved to the lactic bacilli. They produce lactic acid and thus prevent the development of butyric and putrefactive ferments, which we should regard as some of our redoubtable enemies."—Metchnikoff.

"Sour milk is healthful, and the presence of lactic bacteria is not in the slightest degree harmful to those using the milk; other kinds of bacteria, however, are not harmless; many of them are the cause of diseases of one kind or another. If the lactic germs multiply rapidly, the other germs grow scarcely at all; hence the lactic bacteria protect the milk from the growth of other species which would be more apt to produce trouble and harm."—Conn.

"The bacteria surviving Pasteurization are, for the most part, the quick growing bacteria of putrefaction which are inhibited in raw milk by the lactic acid bacteria (italics mine), but in Pasteurized milk they multiply very fast and undoubtedly they are capable of generating poisonous substances."—Jensen.

As to the statement that sour milk is unfit to be used as food and especially for infants, I can only say that of late quite a number of articles have appeared in both the foreign and the American press strongly advocating its use, and especially where there is intestinal disturbance. Among these I note: Acidified Milk in Infant Feeding (Morse and Bowditch, *Archives of Pediatrics*, December, 1906); Buttermilk as an Infant Food (Strauch, *Medical Record*, March 30, 1907); Ramsay (St. Paul Medical Journal, September, 1907); Judson and Cook (*New York Medical Journal*, April 20, 1907); Tissier (*La Tribune médicale*, February 24, 1906) in the treatment of intestinal infections uses pure cultures of certain lactacid bacteria grown in peptone lactose broth.

During the past two or three years there has been an increasing interest in the subject of sour milk, excited chiefly by the writings of Metchnikoff, who urges its consumption not so much for its nutritive worth as for its remedial value in diminishing the amount of putrefactive toxins formed in the large intestine.

In view of the fact that there are nearly one hundred organisms that have been credited with the power of forming lactic acid in sugar solutions, and the further fact that there are a goodly number of acid milks on the market, it seemed to me desirable to obtain further light on the subject. In furtherance of this, Dr. E. J. Lederle and his associates kindly placed at my disposal the resources and conveniences of their laboratories and requested Dr. Charles E. North, chief of the bacteriological department, and his assistants, Dr. Anna E. Young and Dr. O. T. Avery, to aid me in every possible way. To them one and all I desire to express my sincere thanks. Dr. Young maintained the necessary cultures and made the required isolations, and Dr. Avery isolated and cultivated several of the yeasts that were met with.

Prior to the introduction of pure bacterial cultures for acidifying potable milk, Christian Hansen, of Copenhagen, introduced his so called "lactic ferment" for ripening cream to be used in butter making. This was followed by Conn's "bacillus No. 41," and this in turn by Douglas's "butter culture," and lastly by a similar product prepared by Parke, Davis & Co., of Detroit. In January, 1905, I requested this firm to prepare a pure culture of some good lactacid organism in tablet form for the express purpose of souring potable milk. This they have since placed on sale under the fanciful and inappropriate name of "lactone."

At about the same time, or a little later, *La Société le Ferment*, of Paris, brought out a tablet under the name of "lactobacilline," containing a Bulgarian organism furnished by Metchnikoff. In 1905 also an American concern placed on the market a milk souring tablet which they called "keflac." These

<sup>8</sup> This name was already in use as the designation of a chemical product of lactic acid fermentation and therefore should not have been applied to an entirely different thing.

tablets may be taken direct or used for the domestic preparation of sour milk.

Thirty or more years ago, Dr. E. F. Brush introduced his well known kumyss, prepared from cows' milk. In this preparation the fermentation is induced by yeast aided by such domestic lacticid bacteria as might be present in Holstein milk produced under clean and sanitary conditions. It is very mildly alcoholic (1 per cent.) and contains about 0.75 per cent. of lactic acid. It is strongly effervescent. Dr. Brush's kumyss has been so long and so favorably known that present comment is unnecessary.

Shortly after this, Dr. Dadirrian introduced "matzoon," later changing the name of his special product to "zoolak." The fermenting organisms were originally obtained from eastern Europe. This preparation will be more fully considered later.

Among the long known milk ferments, kefir (kephir, kefyur, kefr) has been the subject of several systematic investigations, notably by Kern and by Freudenreich. My own studies were commenced with "kefir fungi" supplied by Merck & Co., of Darmstadt. These consist of light brownish granular masses of small but varying size, insoluble in water or other ordinary solvents. Hardened in alcohol and embedded in paraffin and in celloidin they defied the efforts of two microtommists. Finally I succeeded by soaking them in ethylenediamine in softening them sufficiently to enable me to make reasonably good spreads. These were fixed and stained, and on examination yeasts, bacilli, and cocci were found. Incubated in dextrose broth and in sterile milk a number of different organisms were found and isolated and pure cultures obtained. The first to be studied was a rod form appearing in different lengths consisting in reality of links joined together to form a chain, often without apparent junction points, giving one the impression that the bacillus was of extraordinary length. If stained in methylene blue and then dipped for an instant in alcohol before final washing the junction points become visible, well shown in Plate I, Fig. 1. In certain stages of its growth clear spots or lucidules, two in number, appear in each rod, and on this account the organism has received from Kern the name *Dispora caucasica*. That these are actually spores has been questioned by later writers, probably because they are not affected by the usual spore stains (hot carbol fuchsin, etc.). We were enabled, however, to obtain by culture undoubted spore formation as shown in Plate I, Fig. 2. It will be noticed that the spores are arranged in couplets, thus indicating their origin and justifying the name proposed by Kern. Authors have indicated the existence of second bacillus in kefir, but for which I fail to find any name or special description. In these researches it appeared as rods of varying length, some of them containing points staining more deeply than the main body, or by a different method of preparation not staining at all, but simply showing a row of clear spaces or lucidules as shown in Plate I, Fig. 3. This tempted me to suggest the name *Polyspora caucasica*, which would surely have been appropriate were it not that when the culture was stained with the evamide

blue solution<sup>1</sup> it was found that the long rod appearance was deceptive, and really consisted of a chain of short rods each containing a single spore as shown on Plate I, Fig. 4. The additional elements found in the kefir grains were streptococci and yeasts, as noted by previous authors, to which, however, I paid no special attention. It has been generally assumed that the production of kefir as a beverage required the symbiotic action of the bacilli and the yeasts. However this may be, either bacillus alone or both combined without the presence of the yeast<sup>2</sup> were capable of souring the milk, with production of lactic acid never exceeding 1 per cent. in the specimens tested. I found the milk fermented with the kefir bacilli an agreeable and I believe wholesome beverage. Kefir in potable form (pint bottles) has been placed on the market by the Russian Kefir Co., of Philadelphia.

**Bacillac.** A sour milk preparation under this name has been recently placed on sale in this city. It purported to be made under the supervision of a presumably competent bacteriologist from sterilized skimmed milk, and in accordance with the directions of Metchnikoff, and activated with a lactic ferment furnished by him. Advertising matter states "that its fermentation is not produced by yeasts which contain harmful microbic flora." The name of the bacillus employed is not given, but I assume it to be the *Bacillus bulgaricus*. During June, July, and August, I examined several bottles of bacillac. In every instance I met with yeasts, not only on direct microscopical examination, but also in the cultures from which they were afterward isolated. On agar slants, one gave a white and another a pinkish growth. In every instance also I found the *Oidium lactis* (Plate I, Fig. 5) and obtained cultures from it.

The pint bottles in which bacillac was sold came from different molds and resembled those in which bottled beer is commonly served. The simplest way of accounting for these results is the supposition that the bacillac was dispensed in insufficiently sterilized second hand beer bottles, and that the milk used was not of the highest quality, and also imperfectly sterilized. At the price at which this preparation is sold (25 cents per pint), a better and more carefully prepared article might have been furnished.

The acid content of these several bottles varied from 2.16 per cent. to 2.75 per cent.

The advertising matter that is issued in connec-

<sup>1</sup>See *New York Medical Journal*, November 23, 1916.

<sup>2</sup>In cultures from the kefir grains, yeasts were rarely found; Dr. Yarrow, however, associated with some of them, in fermenting a milk culture of two different yeasts.

Metchnikoff, in his *Science of Food*, states that the kefir grains are composed of a mass of yeasts and bacilli, and that the fermentation of the milk is due to the action of these organisms. He also states that a strongly acidifying bacillus (*bacille bulgare*) isolated from Yaurth is the one to be preferred in the preparation of sour milk. No biological data are given whereby this bacillus may be identified other than the bare fact that it is capable of producing a very large amount of lactic acid, running as high even as 3 per cent. I have never met with any domestic bacillus capable of producing so much lactic acid. Metchnikoff also states that the kefir grains are composed of a mass of yeasts and bacilli, and that the fermentation of the milk is due to the action of these organisms. tion with bacillac may possibly attract the public, but I should hardly think it would the profession.

In June last, I sent copies of the advertisements by registered mail to Professor Metchnikoff, asking whether he endorsed all of the statements contained therein. To this communication I have not as yet received a reply.

Late in October, I examined another recently purchased bottle of bacillac and found neither yeast nor oidium.

*Maadzoun* and *Yoghourt* (Yaourth, Youhourd) are respectively the Armenian and Turkish names of the same product, the common sour milk of southeastern Europe and Asia Minor. For authentic samples of this product, I am greatly indebted to Dr. J. H. Kellogg, of Battle Creek, Mich., who kindly shared with me some that he had recently received from Sofia, the capital of Bulgaria. It reached me in two forms—a creamy liquid and some semisolid, unctuous, cream colored flakes. On direct examination by the usual method (and with the cyanide blue stain) I found a bacillus morphologically similar to the *Bacillus bulgaricus*, a streptococcus and a streptodiplococcus (Plate II, Fig. 5). There were also two yeasts, one of which was round, and the other a long oval. The *Oidium lactis* and the hay bacillus also were found, probably as accidental contaminations.

*Zoolak* (*Matsoon*). These are both trade names for the product manufactured by Dr. M. G. Dadirrian & Sons of this city. It is prepared by adding the eastern ferment (maadzoun) to whole cows' milk first thoroughly sterilized. On direct examination as well as in cultures, it was found to contain bacilli, presumably the *Bacillus bulgaricus* of Metchnikoff, together with yeast cells. Examined direct and stained with methylene blue, I obtained the picture shown in Plate I, Fig. 6. In dextrose broth cultures, quite different appearances were seen, as shown in Plate II, Fig. 1. Comparing the two it will be noted that the bacilli first mentioned are comparatively short (being morphologically similar to those found in bacillac), while in the broth culture there is apparently one long polysporoid bacillus. In the first, the yeasts all appear nearly round, while in the second they are oval. Freshly prepared zoolak is not effervescent, but in one specimen that was quite old, it was extremely so. The acid content of recent specimens varied between 0.9 per cent, and 1 per cent. In the older sample it was above 1.5 per cent. This is much lower than the acidity obtainable with the *Bacillus bulgaricus*. Assuming the presence of this bacillus, the lack of acidity may be due to a partial inhibition by the other organisms present.

By a method of preparation differing from that employed by Dadirrian, maadzoun is marketed by the Russian Kefir Co., of Philadelphia, under the name Yohourd. This is a soft solid, of about the consistence of our familiar junket. In New York it is also found as a customary item in the menu of some of the Armenian restaurants. I have found it of agreeable taste, and undoubtedly wholesome and nourishing.

"Clubberade" in bottles has recently appeared on

sale in this city. It is stated by the maker to be a "predigested milk food, a nourishing fermented milk tonic." On microscopical examination, direct and in cultures, it presents the usual Eastern microbic complex: Bacilli, cocci, and yeast, as shown in Plate II, Fig. 2.

In a culture obtained from some tablets of "lactobacilline" from Paris, that were several months old, the *Bacillus bulgaricus* was apparently dead, but that subtle foe of the laboratory, the hay bacillus, was rampant.<sup>10</sup>

The pure culture of the *Bacillus bulgaricus* employed in these studies was a subculture from some sent by Professor Metchnikoff to a gentleman in this city. In my cultures it appeared as rods of moderate length or of very long ones, but by spirit dipping or the cyanide blue solution were resolvable into their separate elements. Milk inoculated with them developed a very high acidity (Plate II, Fig. 4).

*Buttermilk*. Last but not least, the subject of buttermilk deserves consideration. We all remember the celebrated chapter concerning snakes in Horrebow's *Natural History of Iceland*. It reads: "There are no snakes to be met with throughout the whole island." Concerning buttermilk, I can be equally brief, as I have not been able to find any throughout the whole Island of Manhattan. I here refer to the old fashioned country buttermilk obtained when sour cream is churned.

One day a wagon bearing the name of a large milk distributing concern stood in front of the laboratory. From it in exchange for six cents, I received a quart bottle of alleged buttermilk. An immediate microscopical examination revealed a number of yeast cells in nearly every field. A couple of loopfuls were then added to a tube of sterile wort, and placed in the incubator at 37° C. The following day a loopful of the culture was spread on a slide, fixed and stained and photographed, with the result shown in Plate II, Fig. 3. I next obtained a bottle of buttermilk from another large milk distributing concern. This too contained a rich culture of yeast. I then sought information at headquarters, and an officer of one of the companies gave me the following: "All of our 'buttermilk' comes from our cream station in — County. The fresh milk, after cooling, is put through a separator, and the cream comes down to the city for distribution to our patrons. This leaves the skimmed milk on our hands. The Health Board will not permit us to bring sweet skimmed milk into the city, so the man at our skimming station puts in a starter in order to sour it as quickly as possible, and when sufficiently soured it is brought to the city. Here we mix it with some whole milk, churn it, and after removal of the butter it is ready for distribution." I know of no reason why such a product should not be perfectly wholesome, Metchnikoff to the contrary notwithstanding. My informant did not know the nature of the "starter" that was employed. From an-

<sup>10</sup>The printed matter accompanying packages of "lactobacilline" contain the following: "It comprises various lactic ferments carefully selected and in well defined proportions." There is, however, no precise indication as to what these "various" ferments are, and I am therefore in doubt as to whether the presence of the *Oidium* is to be regarded as a contamination or not. As Metchnikoff is in a position to throw light on this question, it would certainly seem that it was up to him to do so.

other source, I learned that "potato yeast" was frequently used for this purpose. In my younger days this product, kept in every farmer's house as an adjunct to bread making, was commonly known as "potato emptins," "sour emptins," or simply "emptins." This may not fully account for the "milk in the coconut," but it certainly does for the yeast in the buttermilk.

Three facts now appear to be established. First, the Health Board over the signature of its president inveighs against the use of sour milk as dangerous to health. Second, it forbids the entry into the city of sweet skimmed milk. Third, it permits the entry of sour skimmed milk and its sale under a name that suggests quite a different product. If I am in error as to any of these facts, I will gladly welcome a correction, or any reasonable explanation. As I now see it, the Health Board, if it knows the nature of this city buttermilk, has placed itself in a rather illogical position; if it doesn't know it, why has the fact escaped the knowledge of its inspectors, bacteriologists, microscopists, or others concerned with the investigation of our milk supply? To me it is simply one illustration of the imbecile manner in which the entire milk question in this city is being handled.

But this is not all. Desiring to cultivate Metchnikoff's *Bacillus bulgaricus* (Plate II, Fig. 4) in raw milk of the best quality, I added a little of the pure culture to a quart bottle of "certified" milk of the morning's delivery and placed it in the incubator at 37° C. The next day I prepared some slides for microscopical examination, and was not a little surprised at the result as shown in Fig. 1. The bacilli were of course to be ex-

viously contained city made buttermilk, and had not been perfectly sterilized.

*Streptococci.* A field that urgently awaits investigation is that of the streptococci, especially as they are met with in milk.

For lack of a better means of classification, many of the bacteria have been arranged in groups based largely on their morphological peculiarities, and to these groups what might be termed generic names have been assigned, such as streptococcus, staphylococcus, etc., and where differences have been found between different members of the group, based usually on their cultural peculiarities, they have received specific names. Now, if any member of the group or genus has a known pathogenic relation, it tends in the minds of many to cast a slur on the moral character of every individual member of the genus to which it has been assigned. This fact may be illustrated by reference to some of the genera among the higher fungi. Among the basidiomycetes the *Amanita* has certainly a bad name, for we know that the *Amanita muscaria*, the *Amanita phalloides*, and the *Amanita verna* are lethal. On the other hand, the *Amanita rubescens* is both palatable and wholesome, while the *Amanita caesarea* comes down to us as a delicious table luxury from the days of the first Emperor, nearly two thousand years ago. The man who has once chewed a morsel of the *Lactarius piperatus* is like the dog that has killed his first skunk—he never knowingly does it again. On the other hand, the *Lactarius volemus* is good and wholesome, and the *Lactarius deliciosus* is true to name. The *Russula virescens* well cooked and served is a gustatory delight, but if by chance the *Russula emetica* gains entrance to the dish, the delight will be exceedingly brief.

So with the streptococci; some of them we know to be pathogenic, some of them can hardly be so, else the drinkers of the eastern sour milks would ere this have perished. There are still others of whose moral characters we are still in dense ignorance. It would therefore seem that in the streptococci the research laboratories would find a subject worthy of investigation.

*Bacterial Antagonisms.* Throughout the whole of nature we daily witness the antagonisms that exist among the different species in the animal kingdom. Some are created to prey on others—others to become their prey. It is a question not of sentiment but of food. In the vegetable kingdom this condition, though less evident, still holds good, as some plants prey on others, and even on the lesser units among animal life. Among the protozoa there is constant warfare between the larger and the lesser forms; and we are therefore not surprised to find it also true as regards the protophyta. Among the bacterial species such antagonisms have long been known. Herter was the first, I believe, to establish the fact that the lacticid bacteria antagonize those of putrefaction." The immense clinical importance of this fact, however, appears to have been generally overlooked in this country or at least not to have received any extended practical recognition. On this fact, however, Metchnikoff has founded a new epimurine philosophy, especially elaborated in his *Leçons de*

FIG. 1. Yeast cells in "certified" milk inoculated with a pure culture of *Bacillus bulgaricus*. The diameter of the actual field was 68 micra. (Drawn from a photomicrograph by the author.)

pected, but how was the rich yield of yeast to be accounted for? One explanation is that a yeast cell or two had inadvertently dropped from the air into milk before bottling, while another, and I think more probable one, is that the bottles used had pre-

\*"Emptins." Yeast, especially home-made yeast.

†"Emptings." The loaf of beer, etc., used as yeast.

‡"Emptins."

§"Bacteria Medical Science" (London, 1900).

timistes (Paris, 1907). Briefly expressed, his views are as follows: Putrefactive organisms chiefly in the large intestine lead to the production of certain toxins, indol, skatol, etc. These tend to impair vitality and shorten life. The bacteria concerned flourish in an alkaline environment, but perish in one that is acid. Metchnikoff believes that the most convenient and suitable way of supplying this acid environment is by the lactacid fermentation of milk, and further, that the bacilli concerned in the fermentation will make themselves at home in, the intestine and, to a certain extent, colonize it. He especially recommends for this purpose the *Bacillus bulgaricus* isolated from Bulgarian sour milk.

The experiments in antagonism by Herter, Metchnikoff, and others suggested the following: Early in June two broth tubes were inoculated with an active typhoid culture. One was kept as a control, the other received two or three loopsful of the *Dispora caucasica*. On the second and third days both were turbid, but a few days later the tube containing the mixed cultures began to clear up. Before I had an opportunity of making a microscopical examination the tubes were mislaid. On October 14, five tubes of dextrose broth were charged as follows: 1, typhoid; 2, typhoid + dispora from kefir; 3, typhoid + polysporoid bacillus from kefir; 4, typhoid + *Bacillus bulgaricus*; and 5, typhoid + zoolak. After forty-eight hours in the incubator at 37°C., all of the tubes were turbid. The tubes were then kept at room temperature. On October 21 all the tubes were turbid except No. 2. On microscopical examination I found in tube 1 a rich typhoid growth; in tube 2, dispora and typhoid, both rather scanty, with quite a number of little typhoid bacilli clustering around nearly every one of the larger disporas, which they greatly outnumbered; in tubes 3, 4, and 5, rich growth of the added bacilli, with much fewer typhoids than in No. 2. The behavior of the culture in tube 2 is mystifying, and reminds one a little of the Kilkenny cats or of what happens when the Orange and the Green meet on the 17th of March.

A single experiment like this counts but little, but it certainly contains a suggestion, and I leave it to be followed up by those who may have the inclination and proper facilities for so doing.

After considerable personal use during the past six months of milk fermented and soured with pure cultures of the different microorganisms here considered, I am inclined to believe that the principal commercial sour milks for sale in this city could be improved in usefulness by a slight modification in the details of manufacture.

In the effervescent sort, I would recommend the use of a pure native yeast with the addition of a culture of the *Bacillus bulgaricus*.

In the noneffervescent sort, the use of pure cultures of the oriental bacilli and yeasts, with the elimination of the streptococci.

The necessity of using pure yeasts with the elimination of "wild" yeasts and injurious bacteria is now fully recognized by brewers and manufacturers of sparkling wines, and I commend the matter to the consideration of those who are concerned in the preparation of fermented milks.

Examination of one of the small packages of yeast sold by grocers for household use revealed the fact that it was greatly contaminated by the presence of numerous bacilli as shown in Plate II, Fig. 6. Another sample of a different yeast contained cocci. In this case, the cocci were mostly grouped about the yeast cells. Whether they were simply paying a friendly visit or were present with hostile intent I do not know, but strongly suspect the latter. At all events it reminded me of something I once saw among birds. A large owl that had evidently passed the night searching for field mice among the corn shocks found himself stranded and comparatively helpless when the sun rose. He was at last espied by a flock of crows, who gathered around and were busily engaged in bedeviling the poor old fellow to their heart's content.

The addition of the *Bacillus bulgaricus* in the case of the effervescent milks will not lead to undue acidity, as Van Slyke and Bosworth have recently shown (*Bulletin*, No. 292, *New York Agricultural Experiment Station*) that carbonic acid under pressure restrains in a measure the production of lactic acid.

The kefir and other Eastern ferments as they reach us are, owing to their crude method of preparation, somewhat varied in composition, and it would be well, I think, for those who are commercially minded to experiment with cultures containing only the bacilli and yeasts, excluding the oidium, cocci, and any other accidental organisms that may be present.

When maadzoun or any similar product is prepared with sterilized milk, it is, of course, an easy matter to continue it by each day using as a ferment the milk previously soured, but I must confess a preference for raw milk as the basis. In this case, the cultures could be continued indefinitely in sterile milk or in some suitable laboratory medium, and added to the fresh milk each day as required.

There are many who regard good milk at nine or ten cents a quart as an almost unwarranted luxury and the best milk at fifteen cents a quart entirely out of the question. Now, these people certainly cannot afford any of the proprietary sour milks, which hardly can be sold at retail for less than twenty cents a pint. What then are they to do? A simple solution of the matter was presented to me one evening a few weeks ago at the Academy of Medicine. Meeting another Abraham, a descendant of the one already mentioned, I asked:

"What do you think of sour milk as an article of food?" He replied:

"I have it on my table daily in summer; I take a deep soup plate and fill it with fresh milk, cover it and put it in a warm place and the next day it is sour. Sometimes I sprinkle a little cinnamon or nutmeg over it. It is good."

This experiment should be tried with fresh raw milk only, never for obvious reasons with milk that has been pasteurized.

#### Conclusions.

1. The assumption by the president of the Health Department of this city that sour milk is a menace to health is wholly without scientific foundation, and is opposed to common experience in many parts of the world during a period covering thousands of years.

2. Sour milk is wholesome and nutritious and is probably more easily digested than sweet milk.
3. In certain derangements of health it is an important direct remedial agent.
4. The present most available souring agents are special bacteria in common use among certain European and Asiatic peoples.
5. The essential organisms as they reach us are frequently contaminated with unessential and possibly undesirable organisms.
6. The proprietary sour milks should be prepared with laboratory pure (streptococci free) cultures of the desired organisms.
7. The proper organisms preserved in some suitable liquid or solid medium can be readily standardized and administered direct.
8. Whether the bacilli derived from kefir are to be preferred to those from maadoun or *vice versa* cannot at present be dogmatically asserted.
9. The organisms when placed on the market should be under their own proper scientific names and not under a proprietary or trade name. The guarantee behind them should be the reputation of the concern that prepares them.
10. They should be advertised to the profession only and not to the public.
11. It is more than possible that some domestic organisms may be isolated in the future that will prove to be more desirable than those of foreign origin.

256 WEST FIFTY-SEVENTH STREET.

#### ON THE PRESENCE OF SPIROCHÆTA IN PSEUDOLEUCÆMIA, ACUTE LYMPHATIC LEUCÆMIA, AND LYMPHOSARCOMA.

BY WILLIAM CHARLES WHITE, M. D.,  
Pittsburgh, Pa.,

Medical Director, Public & Industrial Hygiene.

AND F. PROESCHER, M. D.,  
Pittsburgh, Pa.,

Pathologist, Allegheny General Hospital.

In the *Journal of the American Medical Association* of December 14, 1907, we called attention to our finding of spirochæta in certain glands of pseudoleucæmia. In a later number of this publication we called attention to the finding of spirochæta in the fluid obtained by aspiration from the glands of a case of pseudoleucæmia and a case of acute lymphatic leucæmia. The fluid obtained from these glands by aspiration was smeared on the cover glasses and stained with an eosin methylen toluidin blue stain of Dr. Proescher after mordanting with the old Loeffler mordant. In these sections spirochæta varying in length from 20 to 120 mikra in length were found in each case, stained a purplish blue color.

We wish now to report our finding in fourteen cases of pseudoleucæmia, acute lymphatic leucæmia, and lymphosarcoma, in all of which we have found the same organism. In this group there were two pseudoleucæmia glands hardened in formaldehyde, furnished by Dr. McCallum, of Baltimore; one pseudoleucæmia gland from Dr. Duncan Graham, of Toronto; one pseudoleucæmia gland from Dr. Henry Christian, of Boston; the tissue from

six cases of lymphosarcoma from the material of Dr. Proescher in the Allegheny General Hospital Laboratory; one case of acute lymphatic leucæmia which was under study during life, and three cases of pseudoleucæmia which were under study during life.

In the postmortem tissues and in the extirpated glands of the living patients we were always able to find the organism which we describe below stained by Levaditi's silver method. In the living cases the organism was found in the aspirated fluid of the glands in all the smears with Proescher's eosin methylen toluidin blue stain. In the case of acute lymphatic leucæmia, the organism was seen in the living state in the fluid pressed from the gland.

From one of the lymphosarcoma cases we were able to transfer a purely glandular affection to a guinea pig by subcutaneous injection of an emulsion

FIG. 1. Clumpy mass from sarcomatous gland, showing mass of spirochæta, some single, some in pairs.

of one of the sarcomatous glands. We have now transferred this to four generations of guinea pigs, having used in all twelve guinea pigs, and in all of these we have been able to find the same organism in the smears by aspiration of glands and stained by Proescher's method. We have been able to see the living organism in the fluid expressed from these glands and have found the organism in the sections of glands stained by Levaditi's method.

This organism varies from all spirochæta previously described mainly in its very great length and in the shallowness of the curves of its body. Both ends of the organism are pointed. Its motility is very sluggish, and its transition from place to place is very slight. On account of its high refractum it was almost impossible to see it. It was become visible on the cover glass as a fine shining point. Upon watching this closely and some time one could see the movements of the body similar to those of a fish. When 1-14 hr. was used in the fixation process the body would come out level with the cover glass, and

finally disappear again from the field. When once seen it was very much easier to again pick out these organisms in the aspirated fluid in the glands of future infected guinea pigs. In a silver section, owing to the great length of the organism, one gets a

FIG. 3.—Spirochæta from pseudoleucæmia by aspirating the glands showing spirochæta.

great many pictures from the organisms being cut at different levels.

We think it best to call this organism which we have found in these cases, and which we look upon as the ætiological factor in this group of cases, the *Spirochæta lymphatica*. Our knowledge of this group of organisms is so limited that future study may prove that this organism does not belong to the spirochæta at all, but for want of a better name, and from the fact that it is always found in the lymphatic fluid and tissues, we have chosen this name as the best at our disposal.

The Proeschler method of staining, which we have found most serviceable in staining these organisms in the smears made from the aspirated fluid in the glands, is as follows:

First—Pass once through the flame. Mordant for one second in the following solution: Loeffler tannic acid, 2 grammes; water, 8 c.c. After this is dissolved add 5 c.c. of a saturated aqueous solution of ferrous sulphate; then add 1 c.c. of saturated alcoholic solution of fuchsin.

Second—Wash the smear in water and dry between blotting paper.

Third—Place for two or three minutes in the following eosin methylen toluidin blue stain. The stain is made by mixing the two following solutions, which are only stable while kept apart and must be mixed fresh for each staining.

Solution 1. Eosin solution:

Eosin, .....	0.5 gramme;
Absolute methyl alcohol, .....	1 c.c.;
Absolute methyl alcohol, .....	9 c.c.;
Absolute methyl alcohol, highest purity Merck, 90 c.c.	

Solution 2. Methylen toluidin blue solution:

Cold saturated aqueous solution methylin blue, .....	4 parts;
(Methylene blue medicinale purissimum Hoechst.)	
Cold saturated aqueous solution toluidin blue, 1 part	
("Gruebler" pure zinc chloride free.)	

To make the stain ready for use take

Eosin solution, .....	2.5 c.c.;
Methylene toluidin blue solution, .....	0.5 c.c.

Mix thoroughly and then allow the cover glass to float smear side down on the surface of the fluid. Put one second in 96 per cent. alcohol, wash in water, dry, and mount.

In smears of the aspirated fluid from all cases of pseudoleucæmia, acute lymphatic leucæmia, lymphosarcoma, and possibly from the spleen and bone mar-

FIG. 3.—Spirochæta from pseudoleucæmia by aspirating the glands, eosin methylene toluidin blue stain.

row of splenomedullary cases, this organism should be found as purplish blue filaments similar to those in the illustrations accompanying this paper. We have never been able to find it in normal glands nor in tuberculous glands, in which we have tried repeatedly to demonstrate it. We feel that the presence of this organism could be readily demonstrated from the fluid obtained by aspiration from the glands of these cases or from the fluid expressed from extirpated glands by examination with the *Dunkelfeldbeleuchtung* apparatus. We unfortunately had not one at our disposal, and could consequently not complete this part of our search.

The ætiology of this group of diseases (including acute lymphatic leucæmia, pseudoleucæmia, lymphosarcoma, splenomedullary leucæmia, chloroma, and myeloma) is so dark a field of hæmatology, and yet their relation to each other is so evident, that in the light of our finding the organism here described constantly in all cases of this group examined by us, never finding it in numerous other conditions and normal cases, and our ability to transfer one type of the malady to four generations of guinea pigs and recover the organism in each case, and never having

found it in tuberculous or normal pigs, has led us to suggest the following classification of these diseases based upon this supposed ætiology:

*Lymphatic spirillosis.*

Acute form, (a) with lymphocytosis; (b) without lymphocytosis.

Chronic form, (a) benign, without sarcomatous change or with sarcomatous change; (b) malign, with sarcomatous change or without sarcomatous change.

BEDFORD AVENUE AND WANDLES STREET.

# SURGICAL TECHNIQUE IN DISEASES OF THE GALLBLADDER AND BILIARY PASSAGES.\*

By JOHN F. ERDMANN, M. D.,

New York,

Clinical Professor of Surgery, University and Bellevue Hospital Medical College.

In preparing a patient for any operation connected with the biliary passages I am accustomed to have the abdomen prepared high enough to encroach upon the extreme limits of the costal arch,

FIG. 4.—Spirochete from acute lymphatic leucæmia; eosin methylene toluidin blue stain (Wilder and Proschner).

and low enough to do an appendectomy through the usual site, should occasion demand.

The incision practised by me is one through the right rectus muscle, either its outer and middle third, or the inner and middle. This incision can be extended downward in a direct line. Free exposure of the cystic and common ducts is readily obtained by rotating the liver. This is done by extending the incision upwards, thereby encroaching upon the diaphragm to quite an extent, or by the method of Bevan, or by the additional transverse rectus incision.

The T incision, made by cutting the fibres of the rectus transversely about the middle of the original longitudinal incision, although done once by me, has never since been found necessary in even the most difficult deeply seated duct work.

Riedel's lobe should always be remembered, as it often resembles, or may be mistaken for, an inflamed and distended gallbladder.

\*Read before the Medical Association of the German City of New York, November 15, 1907.

In cases where atrophy or apparent absence of the gallbladder exists, it is advisable to find the main (cystic) fissure, and then trace downwards and backwards toward the transverse fissure. In these cases, the sand bag or rest as used in duct work, with free upward extension of the incision in the abdominal wall so that rotation of the liver can readily be obtained, is also of great benefit.

In all cases of pericholecystitis accompanying cholecystitis, the adhesions of omentum, etc., should be carefully released. Gauze packing is then placed between the bladder and the released adhesions or viscera before further search is made. When this is done search is made for stones in the bladder, cystic duct, and finally in the hepatic and common ducts.

It is often impossible in a fully or over distended gallbladder that is thickened by either recurring attacks, or by the single acute one, to feel a stone or stones through the wall. The cystic duct may be hidden in its upper (bladder) portion by the fact of elongation or overdistension of Hartman's pouch. The lower (common duct) portion and the common duct can usually be palpated when the foramen of Winslow is patent, although I am never satisfied with palpation of the common duct in a jaundice case, or one recently jaundiced, until I

have opened the duct and palpated its interior. This interior palpation should be done, as Mann has so ably emphasized, with the finger and not a probe, as stones are often passed by the probe that a finger will reveal.

In case the bladder is distended, etc., in such

tioned, I then incise the fundus, empty the contents, and by so doing the pouch of Hartman collapses, allowing free examination of the upper extremity of the cystic duct to be made. This is also a very decided point to bear in mind when doing a cholecystectomy, as in trying to remove the unemptied bladder, particularly in the fat, Hartman's pouch obscures the field of the cystic duct to such a degree as to render the operation not only difficult, but dangerous. Formerly I sought for beautiful specimens of full bladders, but now I am more content to have an operation rendered less dangerous and difficult at the expense of my museum.

*Cholecystotomy.*—When thoroughly satisfied that no work is to be done on the ducts, proper isolation of the gallbladder is made with compress gauze instead of sponges. The fundus is then grasped with two forceps, and a crescentic section taken out between these forceps. The assistant sponges out the leakage of bile, etc., as rapidly as it appears. As the gallbladder empties itself, more traction is made by means of the forceps, and a hand, the left usually, is passed down below Hartman's pouch, and the bladder "milked" of its stones instead of using a scoop in the interior. A final search is made with the finger in the bladder for any concretions that may remain, or may be lodged in the first of Heister's folds.

When the bladder is pronounced empty, a quarter inch calibre rubber tube, fish tailed and with two perforations, is passed down the entire depth of the bladder. A suture of iodine catgut No. 2 is passed through the gallbladder about a sixth to a quarter of an inch from its cut edge on one side, penetrating the tube encroaching upon the calibre very slightly and at a point about one half to two thirds the distance which it originally occupied in the bladder. The suture is then passed through the opposite wall of the bladder and is tied. This step is often repeated by me on the opposite sides, making a crucial suture. A circular suture of the same material is then placed about a third to a half inch below the tube fastening sutures, the tube then pushed down, carrying with it the raw margin below the circular suture. When this is down the circular suture is tied. Should the bladder be a deeply seated one, so called extension of the gallbladder is made by sewing one or more strips of gauze about one and a half inches wide to the bladder's new fundus, and bringing these strips with the tube through the abdominal incision.

In case the gallbladder is long enough I occasionally take one or two stitches through the bladder wall and the parietal peritoneum. A secondary drain outside of the gallbladder is used only when occasion demands.

*Cholecystectomy.*—As a preliminary to this operation I would advise the back cushion or rest as used in common and hepatic duct work. The incision should be ample to allow of free displacement or rotation of the liver.

When the bladder is exposed, if it is of the contracted variety, no preliminary emptying is called for; in fact, in many instances these bladders contain no fluid contents. Removal can usually be done from below upwards.

In case the bladder be distended or thickened, preliminary emptying will aid greatly in exposing the cystic duct, as mentioned in the first part of the paper. In these cases removal is more readily accomplished by attacking the bladder from above. Nevertheless, a combination of both methods of attack will in all probability be used most frequently.

In attacking from below the first step is to isolate the cystic artery and duct, clamping them distally and proximally cutting between and then stripping the bladder off from below upwards.

In attacking the bladder from above the peritoneal covering is incised so that a lateral cuff of about a half inch is released on each side of the bladder. This cuff, after cholecystectomy, falls in upon the raw hepatic surface exposed by the bladder removal. Cleavage is readily found by the finger, and the bladder rapidly separated from its hepatic association. The duct is tied off and the everted mucous membrane edges touched with carbolic acid.

Bleeding from the raw hepatic surface may be profuse, but is readily checked by a few moments' compression with gauze.

I have closed numbers of these cases without drain, but have lately come to the conclusion that a cigarette or simple rubber tissue drain for twenty-four to seventy-two hours provides better sleep for the operator, and does not prolong the convalescence of the patient. Where the case is suspected of marked infection drainage is without question essential.

*Cysticotomy.*—This operation is only done for a stone lodged between Heister's folds, and drainage of the duct, etc. The stone is readily located, and is usually fixed. Traction is made upon the gallbladder, when necessary to bring the duct more easily into the operator's field, the wall is incised, the stone removed, and a drainage instituted either by tube or cigarette method.

*Cholechootomy.*—As a preliminary to bringing the duct in ready reach the use of the lumbar pad or rest cannot be too highly recommended. In addition, free rotation of the liver will bring the cystic and common ducts in a direct line.

*Common Duct.*—In addition to stone as a cause, obstruction may be due to malignancy of the duct itself, or malignancy of surrounding viscera of such degree as to produce pressure sufficient to prevent the flow of bile into the intestines. Operative procedure will then depend entirely upon the extension of invasion, varying from removal of the diseased tissue to a cholecystenterostomy or allied anastomosis of the gallbladder and intestines, provided, in these cases of bladder and intestine anastomoses, the malignancy does not prevent the flow of bile into the gallbladder. Stone may occupy any portion of the duct. When in the course of the duct, its removal is accomplished by incising over the stone, extracting it and then draining the ducts, or preliminary sutures may be taken over the site of the stone, cutting between the sutures, and after extraction tying them so as to close the operative wound and prevent leakage.

When there is reason to suspect or know that the biliary passages are inflamed and infected (cho-

langitis), I sew a tube into the choledochotomy wound with a No. 2 catgut suture, and close the remainder of the opening with one or two more sutures. To guard against leakage infiltration I then place a cigarette drain about the size of an ordinary lead pencil (one third inch in diameter) down to the duct. This is removed about the third to the seventh day, while the tube remains till the catgut sutures absorb. No drainage is replaced, the sinus being allowed to close spontaneously, which usually occurs in about ten to twenty-one days after the operation.

When the stone or stones are situated in the distal quarter to half inch (the pancreatic portion), it may be necessary to approach them either by the transduodenal (McBurney) route, or, and preferably so, by the postduodenal route as described by C. M. Cooper, who reported, in the *Annals of Surgery*, as early as 1903, three cases successfully done by this method.

This method consists of releasing that portion of the duodenum behind which the duct passes, by cutting the peritonæum binding the gut to the back, then rotating this portion of the duodenum downwards and opening the duct, etc.

Operations upon the hepatic duct are performed with the same preliminary exposure steps as used in choledochotomy, the duct usually being opened by continuing either the cysticotomy or the choledochotomy wound upwards, the subsequent steps being relatively the same as in common duct surgery.

Finally the technique of closure and drainage is to be considered. Proper toilet of the peritonæum, the surrounding viscera, and omentum are attended to in the same manner and with the same care as in all abdominal sections.

In closing my abdominal wounds in this region I have been in the habit of late years of closing the peritonæum and transversalis fascia with mattress sutures, as I can then be assured that my first row of sutures will not cut out, as is usual when the ordinary suture is applied. The second row of sutures is a simple running suture of the everted edges of the fascia and peritonæum, resulting from the mattress suture.

The next suture is that of the anterior layer of the rectus sheath, and finally the skin closure suture. If the case has been infected I place a rubber tissue drain in the lower angle under the skin and fat only.

The drainage tube in cholecystotomy and choledochotomy I leave until the fifth to the seventh day, when by trial they are usually found loose. Usually, except in infections of marked evidence, no subsequent drainage material is placed in these channels. The cigarette and gauze drains are removed as the conditions warrant.

Bile excretion is often very much increased in the early morning hours, from 1 to 4 a. m., and is particularly disagreeable by reason of soiling of dressings and the skin irritation resulting. The flow can be markedly diminished by giving the patient a cracker or bit of toast and milk about 11 or 12 p. m., while the skin irritation is overcome by free use of an ointment of ichthylol, from ten to thirty three per cent., or of boracic acid.

It is my habit, and has been for several years, unless the bile is from a markedly infected cholangitis or cholecystitis case, to pinch the tube from one to eight hours daily after the second postoperative day.

In my opening paragraph I stated that the operative field preparation is made low enough to do an appendectomy should occasion demand, etc. I have so frequently seen the appendix also involved that I have been in the custom of removing this organ through the same incision, when possible. This is to me of such importance that I cannot but urge, in considering the technique of biliary surgery, that this additional procedure, removal of the appendix when feasible, is not only warranted, but indicated.

I first called attention to the associated pathological conditions in a paper read in December, 1903, before the Passaic City Medical Association of New Jersey (see *Medical News*, March 26, 1904), and call attention to an editorial in the *Journal of the American Medical Association*, June 29, 1907, in which the association of diseases is strongly presented to the profession.

60 WEST FIFTY-SECOND STREET.

#### THE DIAGNOSIS OF UNILATERAL TUBERCULOUS NEPHROCYSTITIS, WITH A REPORT OF SIX OPERATIVE CASES.\*

By MARTIN W. WARE, M. D.,

New York.

Adjunct Surgeon, Mt. Sinai Hospital, Surgeon-in-Chief, St. Vincent's Hospital.

Although I am not able to materially add to our fund of knowledge on the diagnosis of renal tuberculosis beyond that which has already been contributed by able exponents, yet I hope to offset any disappointment that may be yours in not receiving anything novel, by the presentation of a critical review of the practical workings in arriving at such a diagnosis, based in part on a personal experience of six cases of unilateral tuberculous kidney successfully operated on.

Tuberculous nephrocystitis belongs with other diseases in the borderland of medicine and surgery. It, therefore, is necessary to pronounce this diagnosis on the merits of a strictly clinical and surgical analysis.

The symptom complex of polyuria, pyuria, slight hæmaturia, pollakiuria (frequency of urination), painful urination, as present in greater or less degree, and of these the cystic symptoms predominated. It was, however, the persistence of these latter symptoms, their rebelliousness, and as often their intolerance to prolonged therapeutical measures, mainly unyielding to silver nitrate, that, in most instances, aroused the suspicions of the physician that tuberculosis might be an underlying cause.

Right here, I take it to be opportune to protest against the "hasty" attitude of the physician who rests his diagnosis with "cystitis." This is an end result of some other underlying pathological condition which is the *ferus arripit* of the cystitis. Were this axiom always borne in mind, fewer cases of tuberculous nephrocystitis would escape recogni-

\*Read at the meeting of the New York Medical Society, at the meeting of November 14, 1907.

tion at a date when the lesion is one sided and amenable to surgical measures.

With the rebellious cystitis, the patient is brought to the consultant with the request for a cystoscopic examination, much after the fashion that the laryngologist is asked to use the throat mirror to unravel the mystery of a laryngitis which is called *chronic*. The competent laryngologist would furthermore want to know all physical signs before resorting to this. Such, also, should be the sequence of events prior to cystoscopy. The existence of tubercle in the genital tract, epididymides, testes, vas deferens, and prostate, have to be sought for and excluded, and a repeated search for tubercle bacilli are therefore to be made.

Authorities differ widely, and our position is the same, as to the frequency with which the tubercle bacilli may be found. These discrepancies, I think, are largely due to the personal equation of the examiner, wherefore I hold that such examinations should be left to a bacteriologist. If then, the tubercle bacillus is not found on a cover slip preparation from centrifugated urine, 1 c.c. of the latter should be inoculated, intraperitoneally, into a guinea pig, known to be free from tuberculous taint by the absence of reaction after a tuberculin injection. If the animal does not succumb at the expiration of six weeks, an autopsy is made to search for tubercles. Bloch has recently recommended a more rapid procedure, to inject some of the centrifugated urine into the cellular tissue of the thigh, and to massage and bruise the inguinal lymph nodes which, in the course of a week, become infected from the urine laden with tubercle bacilli. Nowadays the organism is not stamped as the tubercle bacillus until it has withstood the test of retaining its color after prolonged immersion in alcohol and weak acids. A further precaution to guard against contamination of the urine with the smegma bacillus is to withdraw the urine by sterile catheter after the canal has been copiously washed with sterile water. Young and Churchman assert never to have encountered the smegma bacillus after these precautionary measures. Smegma bacilli, if present, occur singly and not in groups as the tubercle bacillus and to expert eyes the smegma bacillus is thicker than the beaded organism of tubercle.

Suter has observed that if an agar tube, inoculated with pus urine, remains sterile, there is every reason to suspect that tuberculosis is at hand. This is, in itself, a justification for culture growth of every cystitis.

It is only at this stage, and with these data in your possession, that cystoscopy is justified. A dictum against the use of the cystoscope has been ventured from the moment we know the cystitis to be tuberculous; but the vindication for the use of this instrument of precision rests upon the basis that from this moment on, the vesical tuberculosis, as an end result of renal tuberculosis, is subordinated to the vital need of knowing which kidney is affected, and finally, cystoscopy is not exploratory, but confirmatory, and should only be undertaken with the express intention of an operation to follow, if the lesion is unilateral.

*Cystoscopy.*—Never has it been our fortune to

encounter a case so early, that the urine was so clear as to permit cystoscopy in the bladder distended with its own urine, as Fenwick reports. Always did we encounter pus, and at times bleeding, necessitating a cleansing of the bladder with repeated irrigations of boric acid solution, to make possible an inspection of the trigonum and the ureteral orifices. In the execution of this essential preliminary cleansing, we often learned of the diminished capacity of the bladder, in itself, a finger post pointing to tuberculosis, and when such contraction reached the limit of a distensibility of but 60 c.c. and less, examination was barely feasible, and that only under profound chloroform narcosis. Otherwise, it is advisable to anesthetize the entire urethral canal and bladder with 30 to 50 c.c. of a 2 per cent. cocaine solution or the less toxic surrogate, 2 per cent. alypin.

Ulcers were but exceptionally encountered, but more commonly dark red spots, some with mucous shreds adherent. The hæmorrhagic areas were very often situated about the ureter and in the intraureteric space. Another frequent finding was an oedematous translucent appearance of the mucosa thrown into folds, which is known as oedema bullosa. This condition is common to many inflammatory conditions in the bladder (Kolischer). At times these bullæ were as small as grape seeds, and very likely to be mistaken for small tubercles. A few times upon close examination fine, barley sized, grayish red, tubercles were found. There is a pretty constant new formation of blood vessels, and these often of quite large size, in the vicinity of the patches. The hæmorrhage was more often seen to come from these patches than from the ureters. An inspection of the ureteral orifices was the next order of routine. The one or the other ureteric meatus was surrounded by the changes enumerated, and if it was visible, discolored urine with flakes could be seen to dribble from it, in contrast to the forcible jet issuing from the other meatus, situated in healthy surroundings. At times, the meatus of the healthy functioning kidney alone was visible, and the ureteric orifice of the other kidney would be obscured by the extensive vesical changes, and appear defunct; yet upon manipulation of the suspected diseased kidney, as suggested by von Bergmann, some pus or flakes could be seen to escape from the diseased area. The diseased ureteric meatus when seen, appeared larger, round in contour, craterized form or golf holed, void of any peristalsis, and likely to be much displaced, which deviation could be estimated by the extreme degree of lateral tilting of the ocular end of the cystoscope necessary to bring the ureteric orifice into view.

These accomplishments of the cystoscope in placing the stigma of vesical tuberculosis on one or the other kidney, or both, was epoch making, but the brilliancy of this epoch was eclipsed with the appearance of the single and eventually the double ureteral catheterizing cystoscopes. Any doubt as to which kidney was now diseased, was to be dispelled by the possibility of separately withdrawing the excretion of each kidney. And there arises such doubt, when the urine is so faintly cloudy that it cannot be seen in its escape from either ureter, and

when condemnatory changes, though present, have left the ureters intact, and when associated with changes in one ostium, the other orifice presents some abnormal appearance. These, then, are pertinent reasons that would seem to mark the indication for simultaneous catheterization of the ureters.

Catheterization of one or both ureters has been practised to advantage by myself numerous times, as an aid to locating the source of pus, yet upon consultation of the records of fourteen cases of tuberculous cystitis, I find that in but three of the six cases operated on for unilateral tuberculous nephrocystitis, was it possible to enter the healthy ureter. Introduction of the ureter catheter into the diseased ureteral orifice, was foiled in four instances by the free bleeding which hæmorrhage, in turn, was also responsible for failure to enter the ureter of the accredited intact kidney in three remaining cases. Quite recently again, I have had two more patients with renovesical tuberculosis, who have not as yet consented to operation, in whom it was possible merely to enter the healthy ureter. The urine withdrawn from the healthy appearing ureteral orifices, in two of the operated cases, showed some pathological conditions, as casts, albumin, pus cells, epithelial cells, and yet these two patients who were nephrectomized, made a good recovery. That such is actually the true working state of affairs in the hands of others, you may convince yourself by a perusal of cases reported by Casper, Albowan, Fenwick, Newman, Kelly, Willy Meyer, Tilden Brown, and Kapsammer, who practise ureteral catheterization, and having learned at times of the pathological excretion of the other kidney, none the less advocated removal of the tuberculous kidney. König, Kuster, Lange, Rössing, Israel, and Senn, who do not perform ureteral catheterization, and see no reason why a totally diseased kidney should not be removed, even if the opposite kidney is partially diseased, report successfully operated cases under such circumstances. We must, therefore, question the real worth of ureteral catheterization. Furthermore, it is likely in guiding the catheter into the ureter of the healthy kidney, via the medium of tuberculous bladder walls and infected contents, to contaminate the urine of that side with tubercle bacilli, and finding them therein, to impugn this kidney as also tuberculous. From this transplantation of tubercle bacilli, the possibility of an infection arising where none existed heretofore, is but fiction thus far. In support of this development of the diagnosis of renal tuberculosis by cystoscopic examination alone, we cite the formidable expert, Fenwick, who considers ureteric meatoscopy paramount for conclusions to operate, and I quote Nitze's words of warning, in his posthumous second edition, "If it is the intention to extirpate one kidney, nothing should be undertaken which might in any way be detrimental for the remaining kidney. Wherefore, I have abandoned double ureteral catheterization, and recommend the use of the occlusive catheter, only to be employed on the diseased side. In addition, a catheter in the bladder will now collect the urine which comes from the healthy kidney only."

Fenwick has recently drawn attention to two

cases, where a descending tuberculous nephrocystitis existed on one side and the intramural portions of the ureter of the other kidney were (tuberculous) diseased by extension of the infection (ascending), and this ureter so stenosed as to preclude catheterization beyond one inch. On bilateral exploration, which Rössing often resorts to, he found the one kidney tuberculous and the other normal.

At this stage we enter the realm of testing the efficiency of the kidney to be left. My experience from the paucity of material is limited, and I dare not speak with authority, save to say that all of these tests are carried out under too artificial conditions.

Two years ago, when interest in this matter was at its height, my attention was attracted by the statements of Casper, of a lowered mortality of 14.3 per cent., and of Kümmel, of that of 10 per cent. From the study of the literature I unearthed these telling data published by me in the *American Journal of The Medical Sciences*, June, 1905: Schmieden up to 1902, collected 201 cases of nephrectomy for nephrovesical tuberculosis, the greater number of which were diagnosed without the aid of the cystoscope, and obtained a mortality of 29 per cent., which corresponds to a like mortality of 29 per cent. in 136 cases reported by Palet. Morris, who denies himself the use of ureteral catheterization, reports eighteen cases with a mortality of 27 per cent., which is again exceeded by König who takes the same stand, and also reports eighteen cases, with a mortality of 33 per cent.

Contrast these figures with those from the advocates of ureteral catheterization: Tuffier, nine cases, no deaths; Tilden Brown, eighteen cases, 7 per cent. mortality; Albarran, 12 per cent. mortality; Bangs, 135 cases (collected), 5 per cent. mortality; and Kuster, seventeen cases, no deaths.

Now, Casper and Kümmel would have us believe that their further reduction of the mortality is due to the still greater precision in the methods for determining operative intervention gained from cryoscopic findings; and yet their mortality is 14.3 per cent. and 10 per cent., respectively, two figures that are surpassed on the one hand by those of Israel who, in 1896, had but 12 per cent. opposed to ureteral catheterization at that time, and, on the other hand, by those of Tilden Brown, whose mortality with ureteral catheterization was 7 per cent. and the 5 per cent. in the collected cases of Bangs.

This last mortality figure agrees fairly closely with that of Rössing, who reports eighty-six cases of nephrectomy, with a mortality of 8.1 per cent., performed in defiance of the results of cryoscopy, though often availing himself of the exposure of both kidneys notwithstanding the accurate uranalysis of the separate urines previously obtained at times by ureteral catheterization. Some exceptional cases of hæmaturia and sepsis will always justify the risk of the removal of the diseased kidney in the face of all odds of the conduct and condition of the opposite kidney.

A very simple way of testing renal efficiency and efficiency, the drop-cystoscope of Volkmann and Joseph, has recently been introduced. Following an incision into the duct of 30 cc. of a fluid prepared and warmed to a per cent. amount of Morrin's

indigo carmin in physiological saline solution (0.9 sodium chloride), the urine issuing from each ureter will appear colored in varying degree within six to twelve minutes. A delay in the appearance of, a diminution in the intensity of the color, and a sluggish delivery of the stream, we are told, indicate disease of the kidney. Fritz Völcker has drawn attention to a type of stream peculiar to renal tuberculosis, in which the colored urine issues after delay as a long continued, slowly moving cloud, instead of the normal, short, quickly passing cloud. This phenomena he harmonizes with the polyuria of the affected kidney often encountered in renal tuberculosis.

At the first congress of the Society of German Urologists, held at Vienna, in October of this year, 1907, it was the universal opinion that the indigo carmine injection was of value in diagnosis of renal function. Suter said it is eliminated simultaneously in six to twelve minutes from both kidneys in health, and Kapsammer, in thirty-seven cases of renal tuberculosis, essayed a delay in the appearance of the stream, and a diminution in its intensity, which differences grew in direct proportion to the extent of kidney lesion. Though tried but a dozen times, I am willing to vouch for its partial value. Nitze has masterfully sized up the situation by saying (*l. c.*), that all these tests for renal function are unavailing, inasmuch as they have nothing to do with that which the surgeon would know, "*whether the one remaining kidney after a nephrectomy is alone capable of eliminating the metabolic products.*"

Once all the evidence for the diagnosis of nephrovesical tuberculosis is in, we try to sustain the verdict by a revision of the palpation of the suspected kidney. Most times it is enlarged, but more often it cannot be felt because it is drawn up under the costal arches by adhesions. In consequence of this displacement by the contraction of the adhesions, the kidney loses its characteristic of respiratory excursions. At times, the opposite healthy kidney takes on an enlargement because of compensatory hypertrophy, and its excursions with respiration are more easily appreciated. If, now, the pain is also referred to this side, an error is very likely. An examination of the pelvic ureter from the rectum or vagina may reveal a thickening, and pressure upon it evoke pain in the penis or side of the affected kidney.

A number of the cases have received an injection of 0.5 to 1 milligramme of Koch's old tuberculin, and the elevation of temperature noted, and also local reactions in the presence of a tuberculous lesion, such as swelling of the affected kidney, with increased pain in it, appearance of blood in the urine, and at times, tubercle bacilli in greater amount than heretofore. The absence of a reaction to tuberculin injection does not count against a tuberculosis being present.

Case of S. G. is one in question, where the tuberculosis was grafted upon a gonorrhoea. With a negative reaction to tuberculin, and all the other means available gone over, we were but able to diagnose a unilateral pus kidney. Even after the kidney was removed, the pus containing pure staphylococci to culture, our belief was finally only verified by the finding of the tubercle in sections of the kidney.

In every way at times renal and ureteral calculi, in the absence of the tuberculous organism,

may simulate nephrovesical tuberculosis, but the use of the x ray will be the final arbiter in these doubtful cases, although in instances of long standing renal tuberculosis, calcareous deposits may also show up in radiograms as shadows not as sharply defined as those from the calculi.

To fasten the stigma of tuberculosis upon a kidney is, therefore, justifiable only from a rigid diagnosis *per exclusionem* in which the tentative clinical diagnosis is supported by the aids of the laboratory, radioscopic and cystoscopic examinations.

In support of the facts reviewed in this article, I herewith append a brief history of the six cases of unilateral tuberculous nephrocystitis in which I operated at Mt. Sinai Hospital in the service of Dr. H. Goldenberg, to whom thanks are due for his valuable advice and care in the management of the cases.

CASE I.—L. S., æt. twenty-six (Surgical No. 88094). Antecedent history, family or personal have no bearing upon the present complaint; no gonorrhoea.

April 29, 1906.—On October, 1905, patient had a suprapubic cystostomy performed elsewhere for suspected stone, which was not found. Urination frequency every half hour, day and night, and bloody and painful as well at that time, and the urine was cloudy. These symptoms had persisted, and a small suprapubic fistula remained after cystostomy. Four months later orchidectomy was performed on the right testicle for a swelling of the testes the size of an orange, which had persisted for four weeks. There was no evidence of a sinus. Since then he had to have morphine for the pain. His chief complaints were frequent micturition, pain at the end of penis, which increased upon urination. There was also hæmaturia, and loss in weight.

Physical Examination.—Dulness and diminished breathing over right apex.

Rectal Examination.—Tenderness over prostate and thickening of both coruna of the prostate. Urine, acid, gravity, 1.020 to 1.028, but at one time were tubercle bacilli found. Urine catheterized in sterile manner *remained sterile upon culture*. After exhibition of 0.5 increasing to 2 milligrammes of the old tuberculin (Koch), the temperature previously normal, rose to 102° F., attended with pains in chest and middle and right side of the abdomen. Examination for tubercle bacilli at this time was again negative.

Cystoscopy by Dr. H. Goldenberg: Right ureteral orifice was normal. Jets of pus could be seen to come from the left ureter. There was no difficulty in washing the bladder clean. A week later an attempt to catheterize ureters (Dr. Ware) was abandoned because of pain. The day following the right healthy ureter was catheterized, under chloroform with 100 c.c. bladder contents. The left was found to be diseased, and could not be entered; to c.c. of slightly blood tinged urine was collected. Reaction of the urine was slightly acid. Albumin, in unappreciable quantity, was referred to the blood from traumatism by ureter catheter.

Microscopical examinations showed pus cells, epithelial cells, and red blood cells.

Operation was performed on May 11th, nephrectomy. Slight pyocyaneus infection of the wound followed. This organism was obtained in culture from the pus in the kidney. The latter was reported tuberculous. Two weeks later the suprapubic fistula closed. Frequency of urination persisted somewhat and craving for morphine was unabated at the time of discharge, one month after removal of the kidney.

CASE II.—L. K. (surgical No. 84964, 1905), female, æt. twelve. Patient had had all the exanthemata and pneumonia at six years of age. No menses as yet. Six months ago she suddenly began to have painful, frequent micturition and terminal hæmaturia. No benefit from bladder irrigations was derived. Urine was cloudy, contained pus cells, epithelium detritus, and tubercle bacilli in great number. Bladder capacity, 50 c.c.

Cystoscopy.—Right ureter showed small slit, left ureter large and crescent shaped and many bloodvessels leading to it. Owing to contracted state of the bladder cystoscopy was performed under chloroform anesthesia.

## Catheterization of ureters:

## Right Side.

Amber.  
Clear.  
Albumin, minute trace.  
Many pus cells, hyaline  
and hyaline granular casts.  
No tubercle bacilli in cen-  
trifuged urine.

## Left Side.

Amber.  
Cloudy.  
Albumin, heavy trace.  
Loaded with pus cells,  
moderate number of red  
blood cells.  
Centrifuged urine con-  
tained tubercle bacilli.

Nephrectomy and resection of two inches of thickened ureter were performed, and drainage instituted. Specimen contained a large pus sac communicating with pelvis; all of the papillae were seat of smaller abscesses. Wound went on to healing and a sinus closed after many months. Relief for six months, then urinary symptoms appeared as before operation. Cystoscopy and catheterization of the right ureter now also showed the presence of tubercle bacilli.

CASE III.—S. G., September, 1905, *et. twenty*. Family history negative. Patient had had a gonorrhoea seven months ago, since which time he had had urinary disturbances, characterized by frequent urination, pain at head of penis during urination, and haematuria. A urethral discharge present contained gonococci. Testicles were normal, and prostate not tender nor enlarged.

Endoscopy.—Urethra was injected throughout the canal. At one point a polypoid growth was seen, but torn off by manipulations, and was not available for examination. There was congestion and oedema of urethra. Urine by sterile catheter was sent to laboratory; reports stated staphylococci. Urine continued to contain pus and blood, and cystoscopy proved a failure. Nothing, in spite of clear return of water, could be made out because trigone was, too injected. Patient was complaining of tenderness over left kidney, and was running a septic temperature. Cystoscopy under gas and ether proved again a failure. Blood culture was negative, also radiograph negative. There was persistent tenderness over left kidney. Temperature continued irregular, intermittent and high; temperatures of sepsis afforded indication for operation.

Operation.—Lumbar nephrotomy with vertical incision. The fat capsule was found very much adherent to surroundings. In trying to separate the adhesions to free the kidney, the patient collapsed, but rallied under intravenous saline infusion so that the nephrotomy could be performed. The kidney was found to be riddled with abscesses. Pus sent to the laboratory was reported to contain staphylococcus, and a small section of kidney removed was reported to show inflammatory changes. The kidney was drained, and the patient made a recovery within a month. At this time he was discharged for out patient treatment with a lumbar sinus and some frequency of micturition persisting. Cystoscopy showed a normal bladder. Six weeks later, January 17, 1906, he returned for operation of persisting renal fistula.

Cystoscopy was performed by Dr. Goldenberg. The right ureter was seen as a round hole, very velvety in appearance and no eversion. The left ureter appeared golf holed. There was eversion of the mucous membrane and numerous punctate hemorrhages about the ureter.

January 19th.—Nephrectomy was performed by lumbar route. Kidney on section contained numerous abscesses. The report of the pathological department stated that the extirpated kidney was tuberculous. Four months thereafter the patient had gained fifty pounds, and he stated that he no longer urinated at night.

CASE IV.—M. K., *et. fifty*, married, four children, October, 1905. Mother had died of tuberculosis; patient had had at age of thirteen dropsy, but there was no other urological history. Patient was in one of the hospitals for perineal abscesses, the sinus persisting.

Cystoscopy by Dr. Goldenberg.—Right ureter was catheterized; contained much pus, while the urine collected from the bladder contained practically no pus. Urine of right ureter showed a few pus cells, hyaline casts, and a few pus cells, representing the output of the left kidney. Subsequently both ureters were catheterized by Dr. Ware, and the right kidney, showed a few pus cells, and a few pus cells. Left kidney, on part of the tract, and trace of staphylococci. No tubercle bacilli were found.

Operation.—Lumbar nephrotomy. Ligament on pedicle slipped and clamps securing the vessels were left *in situ* for six days. Subsequent recovery was uneventful. Post-operative drainage, and drainage of the sinus, was

kidney proved to be the seat of tuberculosis. Revision of perineal sinus was unsuccessful, leakage at times. Now (1907) urine was clear, but patient was attacked with tuberculosis of the wrist, but gained fifteen pounds.

CASE V.—W. N., *et. fourteen*, 1904. Was discharged from the old hospital upon closing, with diagnosis of tuberculosis. He had suffered from cystitis six months ago, and tubercle bacilli were found at that time. Small size of meatus precluded cystoscopy. He returned to the new hospital with original symptoms of frequency of micturition day and night, with occasional blood, but tubercle bacilli were not found in the urine.

Cystoscopy, with the children's cystoscope, size 19 F., showed pus escaping from the right ureter, while the left ureter appeared normal. No small ureter catheterizing instrument was at hand.

Operation.—Lumbar nephrectomy. An uneventful course thereafter, and the boy discharged cured and free of all symptoms one month later. He has been in perfect health since.

CASE VI.—L. M., *et. thirty-five*, May, 1904. One year previously operated upon for abscess of the kidney (nephrotomy) in a hospital of this city, since which time a lumbar fistula of the left side persisted. Urine was cloudy, and there was frequency of urination, twice at night, attended with pain.

Cystoscopy.—Right ureter appears normal; left ureter larger than normal, situated on an oedematous papilla, surrounded by much injection.

Operation.—Lumbar nephrectomy. Kidney was found with difficulty in a mass of dense adhesions under the costal arch, therefore a rib had to be resected. Clamps were left on the pedicle in addition to ligature for security. After six weeks healing was complete, except a small sinus. Patient was seen subsequently; he had gained in weight ten pounds. Urine was clear, but contained albumin and pus; patient complained of dyspnoea and oedema of legs.

Epicrises.—Of these six cases, all but Case IV were in the beginning mistakenly interpreted. One was treated for a vesical calculus, another was operated upon (nephrectomy) for a pyonephrosis grafted on a gonorrhoea, which eventually demanded a difficult secondary nephrectomy. A young girl was treated for six months, in vain, for a cystitis. After nephrectomy of one kidney in the face of inflammatory changes of the other kidney (casts, pus cells by ureter catheter), a tuberculosis of this remaining kidney resulted, possibly, by an ascending process. Still another patient operated upon previously for perineal abscess which did not heal, nor give relief to his urinary symptoms (pyuria) was nephrectomized on the basis of findings with the ureter catheter. Two nephrectomies were performed in spite of pathological conditions of sister organs. No cryoscopy or other tests for renal sufficiency were applied, and no deaths resulted. But these experiences emphasize anew the needs of an early cooperation between physician and surgeon to make possible an early diagnosis.

JOHN LEXINGTON, M.D.

## PATHOGENESIS OF STUMP HALLUCINATION

*A Study of a Case of Stump Hallucination.*

By ALFRED GORDON, M. D.

Philadelphia.

Read at a Session of the American Neurological Association, held at the University of Pennsylvania, Philadelphia, December 12, 1917.

It is a common observation that in cases of amputation of a limb the sensation of the latter remains a more or less prolonged period of time. The patient feels every segment of the absent limb either spontaneously or upon pressure of the stump. The spontaneous sensation is apparently more than

Received for publication, October 10, 1917. Accepted for publication, November 1, 1917.

the sensation provoked by irritation of the terminal ends of the resected nerves.

The notion of a limb is a synthetic conception which is made up of several elementary sensations. Whether the feeling of an amputated limb arises without or with a local stimulation of the stump, it is the brain that congregates the old images, tactile, muscular, articular, and osseous of the limb.

In a large number of cases the spontaneous recollection gradually grows weaker so that after a certain number of weeks or months it disappears totally. The sensation of the lost limb caused by peripheral irritation on the contrary persists for an indefinite time. The question naturally arises, Is the stump hallucination only of peripheral origin?

While there are ample proofs that the cicatricial stimulation constitutes the point of departure of the peculiar phenomenon, the question of its pathogenesis has not been entirely settled, as the so called peripheral view does not explain all the cases. In favor of that view speak cases in which cocaineization of the stump removed the hallucination, cases in which electrization or application of extreme cold or heat reproduced the knowledge of the limb. In all of them there was an expansion of nerve filaments, a neuritis, or a neuroma in the cicatrix, an excitation of which was transmitted to the cerebrum, and the old images were reproduced.

That the cerebrum alone without intervention of the cicatricial irritation plays sometimes an independent rôle in causation of a phantom limb, there cannot be any doubt. Four examples have been presented by Reny in 1899 (*Thèse de Nancy*). Souques and Poisot (*Revue neurologique*, 1905), report a case of a woman of sixty-three, whose right arm was amputated two years prior to the publication of the history. She could see her entire arm all white with the cicatrices every night. Cases have been reported where the sight of very cold water produced a chilly sensation in the amputated arm. There is a well known experiment which consists of striking the place upon which the patient localizes mentally his phantom limb. As soon as it is done, the stump becomes retracted.

Moreover, spontaneous reproduction of images of amputated limbs without the presence of an exciting cause is unquestionably in favor of a purely central origin of the stump hallucination.

If an independent effect of the brain has been observed in some cases, its participation in the curious phenomenon is nevertheless constant, as the brain is the only organ in which hallucinations originate. Whenever the cicatrix of the stump includes terminations of nerves or neuromata, pressure or any excitations of the latter will transmit the sensory impulse to the cerebrum where awakening of the old arm image takes place.

The case I am about to report is interesting from the standpoint of the pathogenesis of the affection. It tends to prove that while the hallucination is easily reproduced upon the least irritation of the stump, nevertheless the phenomenon appears at times spontaneously. Since the cerebral hemorrhage occurred the neuralgic pain from which the patient suffers in the absent arm is decidedly worse. Finally the duration of the malady, viz., twenty-seven years, shows that instead of losing the habit the patient is still able to recall vividly the image

and the sensation of the amputated arm. It is therefore a primary cerebral phenomenon.

His history is as follows:

W. S., aged 51, a railroad man without any special personal or family history, met twenty-seven years ago with a serious accident in which his left arm was crushed. An immediate amputation was considered urgently necessary. Since the operation he had always felt the presence of his removed arm. At first, he suffered continuous excruciating pains which were localized, so to speak, mentally in the absent limb. Gradually, the severity of the pain decreased, but he has never been free from it. Upon examination the stump appears to be covered with a cicatrix. The latter is tender. Pressure upon it causes a sharp pain which extends downward to the entire absent limb. He feels it particularly over the ulnar side of the forearm and hand. He speaks of two lost fingers which are then tingling. The same phenomenon is observed by him whenever he happens to strike the stump accidentally against a hard object, or if anyone passing alongside of him would involuntarily press against the stump. A prick of a pin will also produce pain in the same area. If cold or hot water is applied to the stump, a sensation of cold or heat respectively will be felt by the patient in his phantom arm and hand. Should electricity be applied to the same spot, a tingling will be felt by him down the absent limb as far as the tips of imaginary fingers. So far it can be seen that a peripheral irritation of the cicatrix, which undoubtedly contains the ends of the resected nerves, is the exciting cause of the hallucination.

More remarkable is the spontaneous sensation of the absent limb which originates in him without any apparent external cause. In fact, he constantly feels the presence of the arm. He feels it hanging alongside of the body; he feels the arrangement of the fingers and sometimes their movements. But there is a constant unpleasant feeling, a numbness in the phantom limb. Moreover, he gets sometimes a spontaneous sharp pain of neuralgic character in that arm, which makes him flinch and double up. This pain, he says, runs through the ulnar side of the arm.

A few months ago the patient suffered an apoplectic seizure, following which developed a left hemiplegia. Since this cerebral disturbance the former stump phenomenon became aggravated. The spontaneous pain in the absent arm is more frequent and intense, the numbness causes him more discomfort than previously, and finally the response to stimulation of the stump is decidedly greater.

**Conclusion.**—The appearance of the hallucination upon a physical irritation of the cicatrix of the stump speaks in favor of its peripheral origin. The spontaneous development of the phenomenon when the patient is at rest and without external irritation, aggravation of symptoms after an apoplectic seizure, are all manifestations which originate primarily in the brain. The question of the pathogenesis can not, therefore, be decided in exclusive favor of one or of the other view. Both elements play an important rôle in producing the stump hallucination.

The most interesting feature of the case is the unusual duration of the hallucination. Cases with the stump phenomenon persisting for several years have been reported, but a twenty-seven years' hallucination is very uncommon. The habit of transferring to the periphery all sorts of sensations is due to the association of visual, tactile, and motor images. Normally this habit gets gradually lost; in some cases at the end of a week or a month, and in others at the end of several years. When the hallucination persists for a great many years, the cerebral centres are more or less in a state of an instability. Such a brain cannot be considered normal. My patient is alcoholic. For a number of years he used intoxicating beverages in unusually large quantities (10 to 12 whiskies and as many beers a day). This fact illustrates the validity of the view concerning the cerebral origin of stump hallucination.

1430 PINE STREET.

## POTASSIUM IODIDE IN MENTAL DISEASES.

By J. M. WALKER, M. D.,  
Dubuque, Iowa,

Physician in Charge of St. Joseph's Mercy Asylum for Nervous and Mental Diseases.

The consideration of this subject is not entirely new. However, I hope that perhaps it may be of practical value to the general practitioner, as well as those practising along special lines. I believe potassium iodide has a much wider use in mental diseases, aside from cases due especially to syphilis, and that in most instances we have not been giving this drug in sufficiently large doses. My experience with this drug has been along the lines of special work, viz., nervous and mental diseases, and I am beginning to feel that it is the one drug, if I was to be limited to one single drug, which would accomplish the most good in this class of diseases. I will consider potassium iodide from two standpoints, viz.: (1) Physiological action and dosage not touched upon by most of the textbooks, also method of administration, and (2) its effect and the possibility of enormous doses in mental diseases, especially syphilitic and alcoholic.

Church in his textbook on nervous diseases advises 20 gr. doses three times daily and increase 10 gr. daily until in rebellious or critical cases 100 or even 200 gr. are given at one dose. He also says it is clinically proved that the syphilitic process can gain such a tolerance for either mercury or iodide that their specific effect is lost. I believe the reason for the supposed tolerance to iodide especially is due to the comparatively small doses of the drug, as 200 gr. three times daily is insufficient in a great number of specific cases. I will also recite a few cases of specific and nonspecific mental diseases which have tolerated much larger doses of iodide than recommended by this author.

Pearce in his treatise on nervous diseases speaks of vigorous and thorough application of antisyphilitic remedies, as potassium iodide, in 20 gr. doses, increased to 100 or 200 gr. a day, taken in solution.

Very few of the authors of *matéria medica* and therapeutics, if any, advise more than 1 drachm doses of potassium iodide three times daily.

Following is a brief summary of several cases under my personal care at St. Joseph's Mercy Asylum for Nervous and Mental Diseases. I will not deal exhaustively with history and symptomatology, my object being to call attention to the possibilities of the drug in mental diseases:

CASE I.—E. F., male, single, age forty. Admitted February 2, 1904. Diagnosis: Cerebral syphilis. His history showed that he had had syphilis in 1884, twenty years previous to date of admittance. He was committed to an asylum for mental disease, 1894. At the time he came under my observation for the present trouble, he had secondary and tertiary lesions, showing this was possibly a secondary infection of syphilis. Mental symptoms were of active type, religious mania, loud singing and dancing. He was started on dr. 1 doses of saturated solution of potassium iodide three times daily, and increased dr. 1 daily. Also pills of protiodide of mercury gr. ¼, three times daily, and increased one pill daily until physiological effect had been obtained, when the mercury was withdrawn for a short time, but the potassium iodide was steadily increased until dr. 15 or 600 gr. were reached, which was on the thirteenth day. After a rest of two weeks the same treatment was again instituted. The patient at this time was very much

improved, mentally and physically, and continued to improve until the full effect of potassium iodide was obtained, when he became stupid for a few days, was also nauseated and vomited freely. He was at this time getting dr. 18 or 720 gr. per day and was gaining flesh rapidly. After recovering from the period of stupidity, which lasted four days, he improved steadily until discharged, which was two months after the last course of potassium iodide. This patient was heard from one year later, being under the care of his family physician for a recurrence of the mental trouble. His condition was not improved after one month of treatment with ¼ gr. of mercury protiodide three times daily and potassium iodide in dr. ¼ doses three times daily, advised by his family physician. Large doses of potassium iodide were recommended as outlined in the foregoing, and the patient showed improvement almost immediately and made an uninterrupted recovery.

CASE II.—F. C., male, single, age thirty-seven. Admitted January, 1905. Diagnosis: Cerebral syphilis. He suffered from very active hallucinations and delusions, religious mania. I started patient at once on potassium iodide dr. 1 doses three times daily, and increased dr. ½ daily. This man took the drug uninterruptedly until dr. 30 or 1,200 gr. daily were taken, which was the fifty-fifth day of administration; at this time he was very stupid for four or five days, vomited a number of times and refused all food. There was no marked rash, however; conjunctivæ were injected; face was swollen and puffy. After the fifth day his mental condition became very much improved. He would converse intelligently and do a small amount of work, although he was likely at any time to stop his occupation and begin praying, this feature of his mental disorder being the last to disappear. After two weeks' rest the drug was continued as before and discontinued at the same quantity as the first course. At this time he was writing letters to his sister and had gained twenty-five pounds. After the third course (which was delayed for six weeks, hoping the patient's mental condition would improve) he was discharged cured on February 22, 1907, and has been doing farm work all summer and has been taking dr. 1 of potassium iodide three times daily for seven months without any ill effect, in fact, weighs more and is in better health than ever before.

CASE III.—R. C., male, single, age twenty-six. Admitted July 25, 1905. Diagnosis: Cerebral syphilis. His physical condition was fair. On July 30, 1905, the patient was started on dr. 1 doses of potassium iodide three times daily, and increased dr. 1 daily. Medicine and food, which were liquid, were administered through stomach tube, as he refused all nourishment. After the first week he was taking food voluntarily, appetite was good, and he gained two pounds; he developed rash on face and chest and was slightly nauseated immediately after taking medicine. As potassium iodide was increased, rash and nausea disappeared, patient's appetite was ravenous, and he had gained eight pounds on the sixteenth day, at which time he was getting dr. 18 or 720 gr. a day. He continued to improve until the twenty-fifth day, when he became stupid, refused food, except in small quantities; conjunctivæ were injected; face was puffy and swollen; on the twenty-eighth day he was getting dr. 30 or 1,200 gr. per day. The drug was discontinued at this point, as the patient was vomiting frequently, also had profuse watery discharge from the bowels. He was kept in bed four days, allowed liquid diet and bismuthum subnitricum gr. 30, every two hours, until vomiting and diarrhæa were checked. On the fifth day, August 27, 1905, his mind was clear, except slight religious hallucinations. This same treatment was subsequently repeated twice, with a rest of two weeks between each course. Patient was discharged cured on January 1, 1906. He was afterward employed at the institution until October 20, 1906, and showed no mental impairment or effect of the potassium iodide treatment during this time, and has been working every day since leaving our employ.

CASE IV.—P. O'C., male, single, age twenty. Admitted August 13, 1906. Physical condition good. Diagnosis: Raptus melancholicus, due to hereditary influence. Ordinary treatment appeared to have no effect whatever; in fact, patient's outbreaks seemed to be getting more violent and frequent; he had been getting dr. 1 doses of potassium iodide three times daily for six alternating weeks. I then

mined to increase the drug. He showed improvement after dr. 7 or 280 gr. daily had been reached. It was increased dr.  $\frac{1}{2}$  daily until dr. 28 or 1,120 gr. were being taken, which was the fifty-first day. He had the usual four or five days of stupidity, when he regained his usual mental vigor and was discharged cured, March 13, 1907, one month later.

CASE V.—Wm. H., male, single, age twenty-one. Admitted January 14, 1907. Patient's physical condition was poor. Diagnosis: Cerebral syphilis. Patient had treatment at Hot Springs two years previous, for syphilis. On January 1, 1907, his mental symptoms first asserted themselves. This man was bad, physically and mentally, and required constant attention, as his habits were filthy. Altogether, it was one of the extreme cases of this disorder. On January 16th he was started on dr. 1 doses of potassium iodide, three times daily, and increased dr.  $\frac{1}{2}$  daily until dr. 33 or 1,320 gr. were reached, which was on the sixty-first day. There was some improvement, mentally and physically. After a rest of two weeks another course was begun; he gained flesh rapidly, and his mental condition had improved to such an extent that he was doing some light work, viz., sweeping, dusting, arranging beds, etc. Drug was stopped at dr. 28 or 1,120 gr. At this time he weighed more than ever before, and after recovering from the few days of stupidity, he wrote letters to his family. Potassium iodide was given the third time until dr. 28 had been reached. He was discharged on June 22, 1907, cured. I have kept in touch with this patient and know that he suffers no ill effects from the potassium iodide. He has taken dr. 1 three times daily ever since his discharge.

CASE VI.—F. M., male, single, age twenty-seven. Admitted December 18, 1906. Diagnosis: Cerebral syphilis. This case was of the active type rather than the melancholic. Potassium iodide was given as before until the twenty-fifth day, when he was getting dr. 15 or 600 gr. a day. This was repeated the second time, and patient was discharged cured on June 30, 1907.

CASE VII.—J. L., male, single, age thirty-eight. Admitted March 28, 1907. Diagnosis: Depressive melancholia. His physical condition was fair. Two days after being admitted he had an attack of acute mania; temperature was  $106^{\circ}$ ; pulse 104 per minute. Icebag was placed on his head, cool sponging used, and dr. 1 of fluid extract of ergot administered every two hours. He recovered from the attack in thirty-six hours, but was left very much weakened, and lost twenty pounds in two weeks. He refused all food and was filthy, rather bestial in habits. As soon as he had recovered sufficiently from his acute illness, potassium iodide was started in the usual size doses, given with milk and fed through a tube; this was kept up for thirty-nine days. His physical condition improved very much, and he had gained ten pounds. At this time he was getting dr. 22 or 880 gr. a day. His mental condition was somewhat better. After a rest of two weeks, potassium iodide was again started and reached dr. 28 or 1,120 gr. (fifty-first day). He had added fifteen pounds to his weight, and mental condition had improved so that he was taking food voluntarily. After a wait of six weeks, during which time no improvement was noticed, the drug was started the third time and reached the same as before, dr. 28. He was discharged October 12, 1907, cured.

CASE VIII.—A. K., male, married, age fifty-seven. Farmer. Admitted June 6, 1907. Diagnosis: Alcoholic insanity. This man reached dr. 33 or 1,320 gr. a day at two different times. He has improved mentally and physically, but is still confined in the institution. He has taken as large a dose as any of the syphilitic cases.

CASE IX.—A. J., male, married, age forty-three. Liquor dealer. Admitted July 4, 1907. Diagnosis: Alcoholic insanity, also suffering from advanced stage of pulmonary tuberculosis. Potassium iodide was given after ten days of other treatment had failed to do any good. He improved rapidly, both physically and mentally. When dr. 15 or 600 gr. a day were reached, he was sufficiently recovered to be removed to the hospital; by reason of this, five doses of the drug were missed; the nurse attempted to make up the amount lost, and in doing so the patient was made sick and medicine was discontinued. Had this not happened I am sure he would have taken a much larger amount. This man was coughing almost incessantly and raising large quantities of mucopurulent material. Until 300 gr. a day were being administered, the amount of expectoration was increased markedly; later it ceased almost entirely, as did also the cough. The patient was gaining flesh rapidly, two to four pounds per week, and was dis-

charged August 4, cured of the insanity. I saw this man as late as October 20, 1907, when he had gained, all told, thirty-seven pounds.

CASE X.—Mrs. F., married, age forty. Admitted May 15, 1907. Diagnosis: Puerperal insanity; very active delirium. After treating three months with ordinary remedies, it was concluded to try potassium iodide. At dr. 22 or 880 gr. patient became very quiet, talked rationally, and read the daily papers. When dr. 25 was reached she became very stupid and vomited freely. After a rest of two weeks we gave her dr. 3 of potassium iodide three times daily for a period of thirty-four days, then increased it dr.  $\frac{1}{2}$  a day until dr. 16 were reached, when we were compelled to discontinue it. Later she became restless and noisy, when dr. 1 doses three times daily quieted her; in fact, potassium iodide administered in this way seems to exert a greater hypnotic effect in this case than  $\frac{1}{4}$  gr. doses of morphine which I had formerly used. It is the only hypnotic I am using at the present time in this particular case.

CASE XI.—E. F., male, single, age nineteen. Farmer. Admitted September 17, 1907. Diagnosis: Depressive melancholia. This patient had been treated at home for about one year by the family physician; during this time he had been slowly getting worse. Until October 1 there was no change noted in his condition. At this time I started him on potassium iodide. On the twenty-third day he was taking dr. 14 or 560 gr. daily; his back, face, and chest were covered with large pustules, which cleared up as the dosage was increased. When dr. 20 or 800 gr. were reached, he showed marked improvement mentally; was eating heartily, playing cards, arranging beds, and doing some work in the laundry. On the forty-third day he was taking dr. 24 or 960 gr. daily and was well enough to go home.

During my observation of these cases, I have noticed several things about potassium iodide which seemed to be of importance, viz., it is utterly impossible in most cases to give enormous doses of the drug unless the patient is on a full diet and given immediately after meals. However, I have divided the doses so as to give a comparatively small dose between meals, but not with the same tolerance as when given immediately after meals. I use the saturated solution in water or given in milk; contrary to the usual custom of considering dr. 1 of the saturated solution as containing gr. 1 of potassium iodide in computing my dosage, I figure according to Potter dr. 1 of saturated solution as containing 40 gr. of potassium iodide; hence the apparent smallness of the dosage in grains as compared with the usual method of computing 60 gr. to dr. 1, which would increase the number of grains one third of the full amount (as 1,200 gr. usually considered 1,800 gr.).

I have yet to find a person, especially of the class of cases cited, who was unable to take very large doses of potassium iodide. I have also noted in most every case we have what I may call a primary eruption, situated principally on the chest and face; in most cases this occurs at from 300 to 500 gr.; also slight nausea; both of these conditions disappear upon dosage being increased. This seems to be the rule in nearly every case, and, in so far as my experience goes, I have found in a good percentage of cases of cerebral syphilis, if treatment is begun within three months after mental impairment is first noticed, the patient will invariably regain his normal mental faculties. The eruption and nausea spoken of seem to be a primary physiological effect of potassium iodide, as nausea disappears and the skin clears up on increasing the dose to its limit or full physiological action, which is evidenced by the patient's face becoming puffy and swollen, conjunctiva injected, abundant secretion

from the mucous membrane of the nares and bronchi, severe vomiting, acne-form eruptions covering nearly all of the body (however, this may or may not be present); diarrhoea, loss of appetite, and stupidity, which lasts from four to five days; during the period of diarrhoea and emesis pulse is increased ten to fifteen beats per minute, and lasts for about forty-eight hours, after which it becomes normal.

I have had some trouble in getting the dose above 300 to 400 gr. in a few cases, but only when it has been impossible to induce the patient to eat heartily, and I have a number of patients whom after leaving the institution have been taking dr. 1 doses three times daily for months without any deleterious effect whatever—in fact, appears to exert a decided tonic effect and increase the appetite. In Case IX the effect of potassium iodide appeared to be very marked, as the tuberculous process was well advanced and bacilli had been demonstrated in the sputum; the man did not get any other medication whatever. Hence I feel that potassium iodide was responsible for the mental improvement, also the decided change in the progress of the tuberculosis. It may have been its alterative effect alone, or by reason of its being excreted by mucous membranes a sufficient amount may have reached the seat of the trouble to exert its antiseptic influence. At any rate, I believe it to be worth a trial in selected tubercular cases.

Grünberg reports cases to sustain his assertions in regard to the frequently beneficial action of potassium iodide and of mercury on primary tuberculous processes in the nose and throat. Syphilis could be positively excluded in his cases, and he thinks that some of those that have been published as syphilitic affections of the upper air passages simulating tuberculosis and cured by potassium iodide or mercury were in reality purely tuberculous processes.

Stern, of New York, recommends a saturated formic acid iodide solution in pulmonary tuberculosis and alleges improvement or cure in 70 per cent. of eight hundred patients.

There may be in the minds of some a question as to whether or not potassium iodide is being digested or passes directly through the bowels without any change. As evidence that I think it is, I can point to the steady gain of flesh, the marked improvement in the patient's mental condition as the dosage is being increased, especially the syphilitic cases, also the urine of every case gives positive tests for iodine.

#### GLAUCOMA IN THE YOUNG.\*

By C. A. VEASEY, M. D.,  
Philadelphia.

At the Philadelphia meeting, 1907, I had the honor of reporting before this section, in conjunction with Dr. E. A. Sherris, who made the pathological and

examination, of some of simple glaucoma in the young, the history of which was briefly as follows:

A B. an unmarried colored woman, was first seen in April, 1902. Her family history of any similar cases could

\*Read before the Section on Ophthalmology at the annual meeting of the Association of Ophthalmologists, November 19, 1907, at Philadelphia.

be elicited. A grandmother aged ninety-three, and an aunt, aged ninety-one, were still living and possessed good vision. At sixteen years of age the patient had typhoid fever, during which there was an indefinite history of a mild attack of inflammation in both eyes. The patient is positive, however, that the vision of the right eye began to fail during convalescence from the attack of fever. There were at no time any inflammatory symptoms or pain. The vision gradually diminished until it was finally entirely lost when she was nineteen years of age, or about three years from the beginning of the disease. From this time on there were occasional attacks of severe pain, becoming more and more frequent, and located by her in the eyeball, temporal region, and along the side of the head, and it was for relief from this condition that she sought advice.

Examination showed a divergent strabismus of 45°, no inflammatory symptoms, and a typical complete glaucomatous cup, the bottom being best observed with —S. 9 D., the macular region appearing practically emmetropic.

Ophthalmoscopic examination of the left eye showed a normal disc of healthy appearance with a small physiologic cup and pulsating veins. The tension was normal.

The refractive error of the left eye was carefully corrected, and after a year's treatment of the glaucomatous eye with myotics locally, and sodium salicylate, bromides and the various analgesics internally, the eye was enucleated. The sections were exhibited at the time of presenting the paper, and showed a very deep kettle shaped excavation of the nerve, the lens was unusually large, the epithelial cells markedly pigmented at and beyond the corneal limbus, and there was also found considerable pigmentation between the bundles of the ciliary muscle and around the loose meshed tissue between the canal of Schlemm and the angle of the anterior chamber.

Here was a case, therefore, in which chronic simple glaucoma began in the sixteenth year of age, and which rapidly progressed to total blindness in the nineteenth year, with no appearance of glaucoma in the other eye thirteen and a half years later.

Eight months ago, three and a half years after reporting the case and seventeen years from the appearance of glaucoma in the first eye, the patient came to see me complaining of dim vision in the remaining eye, which she stated had been observed first three months before. Ophthalmoscopic examination showed a beginning glaucomatous cup, the vessels being crowded to one side and the visual field being considerably contracted. The tension was slightly elevated. Myotics were faithfully employed locally and strychnine and nitroglycerin internally, but in spite of this the cup of the optic nerve became more and more extensive and the field of vision more and more contracted. When it was found after some weeks that the myotics in gradually increasing strengths did not seem to check the advance of the glaucoma, iridectomy was proposed and respectfully declined. Eight months have now elapsed, the patient having always declined operative procedure whenever such was proposed, and although the myotic treatment, together with optic nerve stimulants, have been carefully and faithfully employed, the patient is now almost blind, there remaining but a small amount of eccentric vision, and the field being restricted to a small limited area.

1831 CHESTNUT STREET.

#### TYPHOID FEVER AND TETANUS—A CASE.\*

By A. V. MASON, M. D.,  
Elmira, N. Y.

Typoid was the first disease, followed by tetanus. The phases of onset and progress. Tetany is an uncommon disease and not particularly well defined. Some authorities consider it akin to hysteria, others as a tetanoid, and still others as a disease of infection. Therefore the following case is presented as one devoid of interest, even if full concurrence is not had in the diagnosis:

Read before the Association of Physicians and Surgeons, November 19, 1907, at Philadelphia.

\*Read before the Association of Physicians and Surgeons, November 19, 1907, at Philadelphia.

five days before, had returned from a week's visit in the country. He presented the symptoms ordinarily ascribed to intestinal parasites, and as his mother said he had been troubled with worms, he was prescribed for accordingly. There was no headache, no coating on tongue, no evidence of fever at this time, although his mother said he had been feverish for two or three nights. There was, however, marked prostration and irritability, which his mother thought was due to the child's having played overmuch the week previously.

I was called again at 2:30 a. m., August 5th. The child had been feverish and restless all night, and delirious since 12 o'clock. I found him tossing from side to side, and talking incessantly in a voice that could be heard half a block. His pulse was rapid, full and strong. I did not get count of pulse or temperature. The medicine given at my first visit had acted freely on his bowels with apparent benefit, and the child had seemed quite well for the past two days, except for the continued and progressive weakness. I quieted his present excitement with chloroform. At 9 a. m. he seemed quite well—pulse 88, temperature 99.6° F., but his right eye was strabismic. The rest of this day, the 6th, 7th, and 8th passed without any marked symptoms, the depression gradually increasing, the pulse running from 88 to 96, the morning temperature from 100° to 100.8° F., and the evening temperature from 100.8° to 102° F. On the 7th a diagnosis of typhoid fever was made.

On the 8th, while passing the house at 7 p. m., I was called in on account of convulsion. I saw the child within five minutes of occurrence of a fit and found his body flexible, but arms slightly rigid, with fingers closed in palms. His mother stated that the whole body became rigid. Temperature, 100.2° F.; pulse, 98; respiration, 32. There was fall in temperature since 5 o'clock of 2.4°. During the night he was very restless.

August 9th.—Temperature ranged from 99.6° to 102° F.; pulse, 90 to 100; respiration, 30 to 34. Alternating contraction and relaxation of fingers more marked on the left side—occasionally affecting the arms, readily induced by Trousseau's test for tetany. Restlessness continued, with occasional periods of sleep from twenty minutes to two hours duration.

August 10th.—Temperature range from 99.6° to 101° F.; pulse, 84 to 90; respiration, 26 to 28. Left arm was paralyzed, fingers closed in palm, could readily be extended, but on being released slowly closed into palm again. Trousseau's test was positive on muscles of arm, and here it may be remarked that throughout the disease, even when in deep stupor, the patient's muscles responded to this test. Delirious from 11 a. m. to 4 p. m.

August 11th.—Temperature range, 101° to 102° F.; pulse, 84 to 120; respiration, 12 to 24. It will be noticed the beginning of the remarkable fluctuations in the pulse rate. The diminished number of respirations appeared to be due to spasm affecting the muscles of the chest, which, however, was of short duration. At this time the back of the neck was found to be tender, and head was slightly extended. He was delirious by spells. During the night there was deep stupor.

August 12th.—Temperature range, 100° to 105.6° F.; pulse, 94 to 160; respiration, 28 to 40. Power of deglutition was lost; whole left side was paralyzed, facial muscles rigid and jaws set; left hand and foot were strongly adducted. At the morning visit I found right arm intermittently contracted and relaxed. At noon the whole body became rigid by spells; intervals of relaxation were few and short. Blood was now taken for Vidal test, which promptly gave positive reaction. Just here I would remark the difficulty in getting even a drop of blood. The lobe of the ear was punctured, then the finger tip, then the ear again several times before a drop of blood could be obtained.

August 13th.—Temperature range, 102° to 104.4° F.; pulse, 120 to 172; respiration, 38 to 56. The whole body was strongly rigid most of the time. Periods of relaxation were longer apart and imperfect. Here the case presented the typical features of the complicating disease. The fingers contracted into the palms; the wrists were strongly flexed; the forearms flexed and crossed with the elbows close to the sides; the toes and ankles flexed and adducted; the knees semiflexed; the right vertical and the left horizontal, the facial muscles were rigid, and the head slightly extended. Towards evening the muscular rigidity was less

marked, and alternating contractions and relaxation were noticed on the right side.

August 14th.—There appeared to be signs of improvement. Temperature range, 98.6° to 102.4° F.; pulse, 120 to 178; respiration, 30 to 54. Rigidity of arms and legs was less marked; he moved head slightly; opened eyes occasionally; had limited voluntary motion of right leg and both arms, and of the left leg in very slight degree. Face muscles were still rigid, but less pronounced than yesterday.

August 15th was a day of hope. Temperature range, 99.4° to 101.6° F.; pulse, 120 to 160; respiration, 30 to 56. All the symptoms improved except the breathing, which was irregular and catchy. There was general muscular rigidity; he could open his eyes and mouth a little, and was sensitive to touch; he was in a semiconscious state.

August 16th.—Patient was rapidly growing worse, except muscular rigidity, which during the day was entirely relieved. Temperature range, 102° to 104.8° F.; pulse, 160 to 264; respiration, 28 to 68.

August 17th.—Temperature range, 102.8° to 108° F.; pulse, 200 to 260; respiration, 40 to 88. Patient died at 3:30 p. m.

In review I have to add that the bowels had been freely opened at the beginning of the sickness and remained so throughout. Elimination was sought by frequent high enemas of normal salt solution, which generally came away clear. Nothing given by rectum was retained, and when endeavor was made to nourish by this route it failed completely.

The kidneys acted freely and urine was discharged normally until the 15th, when continuous bed wetting was noticed, and the bladder thereafter relieved by the use of the catheter.

His diet consisted of malted milk, junket, and albumin water administered by mouth until the 12th, and then, after one day's delay in trying to nourish by rectum, was given regularly by nasal route until noon of the 17th.

Remedial measures seemed almost entirely without effect, except in the temporary relief of certain symptoms. Increase in temperature was met by cold or tepid sponging, according to state of skin and pulse. From the first the pulse was very weak and various cardiac stimulants were resorted to without satisfactory results. For the rigidity the warm pack, and twice the tub bath, were used with apparent benefit. Time and again difficulties in respiration were relieved by the use of atropine or sulphuric ether, but notwithstanding the disease, or diseases, marched steadily on to lethal issue.

Now several interesting if not particularly important questions present themselves, viz.:

1. Did this child have tuberculous or cerebrospinal meningitis?

2. Was the case one of typhoid with the complication of cerebral or cerebrospinal congestion?

3. Were there two separate diseases, distinct entities, complicating and interfering each with the other?

Regarding the first, there was nothing in the history pointing to tuberculous infection. The usual prodromal symptoms of such condition were absent. There was no headache, no vomiting except at the outset in connection with the operation of the physic, and no fever except at night. There was no hydrocephalic cry or anything approaching it. The only pain complained of was a vague discomfort and tenderness in the abdomen. The pulse was not rapid at first, nor did it subsequently assume the character of the tuberculomeningitic pulse. The pupils were dilated from the beginning. Convulsions, tremors, paralyses, and spasms may occur in tuberculous meningitis, but they are all quite different from those in the case cited.

The ordinary form of cerebrospinal meningitis may have the initiatory symptoms of headache and pains in the back, but it is more apt to come on suddenly with chill, vomiting, and headache, none of

which occurred in this case. Even in mild cases the headache and nausea are so uniformly present as to be regarded almost as essential to the disease. Spasms also occur, both tonic and clonic, the former tetanic in their character, and the latter having little resemblance to the gradual contraction and relaxation which marked the case under consideration. In cerebrospinal meningitis, Osler says that "strabismus is a frequent and important symptom." It will be remembered that this was an early symptom in my case, manifesting itself on the fifth day. This, with the active delirium and strong, full pulse at first, was strongly suggestive of meningeal inflammation, but the subsequent course of the disease was hardly consistent with that view. Osler further says: "Of sensory symptoms, headache is the most dominant and persists from the outset." "Delirium occurs at the onset occasionally of a furious and maniacal kind," and, he adds, "the delirium gives place in a few days to stupor, which, as the effusion increases, deepens to coma." In this case there was no time when the patient could be called comatose. The deepest stupor was on the eleventh and twelfth days, but even then he gave evidence of discomfort on being moved or disturbed.

In regard to meningitis as a complication of typhoid, Osler remarks, "Meningitis is extremely rare." He did not find it in any of his autopsies, and it occurred in only eleven of the 2,000 Munich cases. He further states that he has examined post mortem three cases with pronounced cerebral symptoms, in two of which the diagnosis of cerebrospinal fever had been made. "In not one of these was there any trace of meningeal inflammation, only the most intense congestion of the cerebral and spinal pia," and continues, "Stokes's dictum that 'there is no single nervous symptom (in typhoid) which may not and does not occur independent of any appreciable lesion of the brain, nerves or spinal cord,' is too often forgotten."

Of tetany with typhoid, he writes, "True tetany occurs sometimes, and a number of cases have developed in certain epidemics. It may set in during the full height of the disease. This complication is extremely rare in this country, and Janeway, as far as I know, has alone reported instances."

As for tetany itself, various causes are ascribed. In children it is frequently associated with rickets. It has followed extirpation of the thyroid gland. Dilatation of the stomach is frequently found in fatal cases, and it is stated that any exhausting disease may be a possible cause. Its pathology gives no constant or characteristic lesion. J. Madison Taylor in Sajous's *Encyclopædia* says: "The evidences point to the conclusion that tetany is a disorder of the nerves, somewhat generally distributed, and of toxic origin."

A tender fishbone lodged in a tracheus will usually not cast a shadow on the x-ray plate. In such a case bronchoscopy and auscultation are more reliable diagnostic measures. In addition to a variety of moist râles, one may hear, associated with the inspiratory or expiratory murmur, or both, a musical or vibratory note, when a bone or pin lies in the bronchus.—From *Five Hundred Surgical Suggestions*.

## Our Readers' Discussions.

### A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXIX.—How do you treat post partum hemorrhage? (Closed December 16, 1907.)

LXX.—How do you distinguish alcoholic stupor from other conditions resembling it? (Answers due not later than January 15, 1908.)

LXXI.—How do you treat gallstone colic? (Answers due not later than February 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXVIII has been awarded to Dr. Arthur S. Risger, of Blackwell, Oklahoma, whose article appeared on page 1209 of the preceding volume (LXXVI, No. 26).

### PRIZE QUESTION NO. LXVIII.

THE TREATMENT OF THE VOMITING OF PREGNANCY.

(Concluded from page 1216.)

Dr. William H. Wells, of Philadelphia, writes:

The treatment of the vomiting of pregnancy will depend on the cause and time of pregnancy.

We have the slight morning nausea caused by a nervous reaction produced by the growing uterus. This form is usually seen in the early weeks, particularly of a first pregnancy. It is felt commonly in the early part of the day or on rising from the recumbent position. The blood serum should be examined so as not to mistake this condition for the much more serious form to be described later. Allow the patient to take her breakfast lying down. Her diet should be light, easily digested liquids prepared in a dainty manner and always in quantity a little less than the patient wants. No smell of cooking should be allowed near the patient. The bowels should be kept open, preferably by enemata, one of the normal salt solution doing well enough. Minute doses, say 1/24 to 1/40 grain of calomel with 1/2 grain cocaine hydrochlorate and 5 grains cerium oxalate every four to six hours will do for drug medication. The condition usually passes in from four to six weeks.

Nausea produced by uterine displacements.—These usually have pain accompanying the nausea. Other symptoms characteristic of displacement are usually found. It is obvious that the correction of the uterine displacement will cure the nausea. The uterus must be put back in position; usually this may be done by tampons until it is large enough to ascend out of the pelvis. If the organ cannot be replaced vaginally, it must be done by abdominal section.

Hyperemesis gravidarum is often a trying condition of pregnancy. The diagnosis is often difficult, as it so much resembles pernicious nausea. The diagnosis must be made by a careful study of the case in conjunction with frequent examinations of the blood and urine. The blood will not show the

changes found in the toxæmic form, and the excretion of solids will be fairly good. Also the excretion of free ammonia nitrogen will be comparatively low. Except in hysteria in an albuminuric subject there should be no albumin and casts in the urine, and no oedema. The patient should be put to bed under the care of a reliable trained nurse. She should be in a quiet room, away from disturbing elements of life, and as much as possible with the nurse alone. All displacements of the uterus should be corrected if present. Her bowels should be kept open by small doses of calomel, say 1 grain in divided doses, if she can retain it, or by aperient waters, if well borne; otherwise a daily enema of normal salt solution or magnesium sulphate  $\frac{5}{8}$  j, and glycerin,  $\frac{5}{8}$  j, in a quart of soap suds. Her diet should be of liquids—milk or chicken broth or small quantities of champagne. The chief point in the diet is to give small quantities of food and at frequent, regular intervals. Mental suggestion is often useful in quieting the condition.

The most dangerous form is the toxæmic, found in patients suffering from the toxæmia of pregnancy, either of renal or enterohepatic form. This type may occur at any time in pregnancy, but in my own experience has been seen most frequently from the fourth to the seventh and a half months. It frequently occurs earlier. There are usually some blood and urine changes associated with the condition. In the latter the solid excretion is decreased, the excretion of urea and urea nitrogen is less than normal, while the output of free ammonia and certain other substances is increased. The patient is constantly nauseated, breath foul, temperature somewhat raised, as is also the respiration and pulse. Frequently the patient does not seem to lose weight.

The vomitus is composed first of the contents of the stomach, later bile, and in the late stages the "coffee ground" vomit. The urine is scanty and frequently passed in small quantities; in the earlier stages it is of lower specific gravity, and usually contains albumin and an increased output of free ammonia or nitrogen in other combination than urea. In the latter stages the urine may be concentrated.

The treatment consists in putting the patient to bed in a quiet room. An attempt should be made (1) to feed the patient by the mouth with predigested milk or broth; this usually fails; (2) to feed the patient by the bowel after having thoroughly evacuated all fecal matter. Too much time should not be lost, as these attempts for rectal feeding are too often only a slow form of starvation. The subcutaneous injection of salt solution may do for a short time. Usually we are forced to empty the uterus to save the patient's life, and it should be done early, as too much time is usually lost in trying other methods of treatment.

*Dr. Eugene R. Corson, of Savannah, Ga., remarks:*

The simpler forms of this trouble require little or no treatment. The condition may be regarded as a natural one, to be borne like other disagreeable features of pregnancy; nor does the general health suffer from it. When more pronounced, treatment becomes necessary. Still, up to a certain point, proper hygienic regulations, a selected diet, suitable exercise, absence of coitus, a proper psychic surrounding, and the simpler drug treatment, control

the majority of the cases. It is here that cerium oxalate, nux vomica, ipecac, ingluvin, calomel, haphazard doses of bromide, or what not, relieves the case, and the successful drug has gained a new votary. Again, there may be certain local conditions, an unhealthy vaginal mucous membrane, erosions of the os, an endotrachelitis, or a misplaced uterus, all of which should be looked to on general principles.

Yet, while we shall probably see an improvement from the local treatment in the simpler or ordinary cases, where the disease assumes the more violent form, my experience is that we must look for help elsewhere. The worst forms I have seen have been without any apparent local trouble. As to the value of cervical dilatation, a practice made popular for a time by a very capable man, it may be valuable in some cases of the simpler type, but I believe it is precarious and uncertain in the violent forms, cases which require prompt action in a different way. And rectal feeding, which has been found valuable in a few cases, will also fail when most needed. The bromide sleep makes both these methods unnecessary.

Let the condition become more pronounced, let it pass a certain point, and the problem which confronts us is a wholly different one. Now, any old thing will not do; the ordinary drugs not only fail, but they aggravate, for every additional spell of vomiting carries the patient further down stream. Thus a systematic treatment becomes necessary, with a keen regard to every possible detail—the trained nurse, everything by clockwork, and the utmost vigilance.

I have found but one drug upon which I can rely, sodium or potassium bromide, and since I have learned *how* to use it, it has become, to my mind, the one sovereign remedy. In the simpler cases it can be given by mouth in 20 grain doses in plain water, at such intervals as the case demands, and it is a drug which the stomach stands well. In the severer form, where everything is vomited, it can be given by rectum in one or two drachm doses every two, three, or four hours, and it is a drug well borne by the rectum. In the majority of cases the vomiting will cease when a pleasant somnolence has been induced. In the severest cases this will not be sufficient, and the regular bromide sleep will become necessarily a gentle sleep withal, for the patient is easily aroused and will take her nourishment without trouble every two, three, or four hours, as the case may be. To put the "vomiting centre" asleep we must put the patient asleep.

The food I have found best suited for these cases is ice cold buttermilk or kumyss, or egg albumen lemonade. Individual peculiarities may require some other forms of liquid diet.

Patients can thus be kept gently asleep for several days, when they can be allowed to come somewhat out of the sleep, and the vomiting watched. I have had several bad cases cured by a week of such treatment. Personally, I have never seen it fail, while I admit, of course, that there may be cases where everything fails, and an induced miscarriage becomes the only remedy. When this measure has to be considered do not delay too long. My practice is to introduce a large leaded bougie

well up into the uterus under the strictest asepsis. Labor comes on usually in twenty-four hours, and it is wonderful how the patient's condition improves immediately or soon after the passage of the bougie.

Before I used the bromide treatment I was obliged to induce a miscarriage in four cases, if my memory serves me. Recently in a case complicated by typhoid fever this treatment acted admirably and labor came on later spontaneously at the seventh month.

The patient, of course, is kept flat on her back, and in some cases the head lowered. I also use an ice bag on the epigastrium, and I may give  $\frac{1}{4}$  grain calomel triturates at short intervals to help the upper bowel, and *increase the flow of urine*, so frequently greatly diminished in this trouble. Should the bowels be loose, I use bismuth subnitrate in drachm doses. If the pulse is very rapid, a common condition in bad cases, I use aromatic spirits of ammonia with the bromide. For drinking water I use Irish soda or ginger ale, but no form of alcohol.

Other forms of intractable vomiting, due evidently to this same reflex pyloric spasm, are relieved, if not cured, by this wonderful drug.

*Dr. B. W. Wilson, of Youngstown, Ohio, states:*

There is no affliction that presents so marked a variance of symptoms as does the vomiting of pregnancy. Its cause is mainly reflex from the growth and dilatation of the uterus and cervix, with possibly some degree of toxæmia and consequent irritation of the stomach. Its treatment must be governed accordingly.

The very mild cases of "morning sickness," with occasional vomiting, may require little more than a cup of hot water with a little salt or sodium phosphate. This should be taken in the morning, twenty to thirty minutes before rising. The bowels should be kept loose, and daily regularity at stool should be enforced. The diet should contain plenty of fruits and vegetables, with a liberal supply of water. Cas-cara should be taken with morning and evening meals, if there is a tendency toward constipation. A saline enema may be required if the bowels do not move freely.

When the weather is favorable the patient should take daily walks in the open air or ride in a comfortable carriage. She should avoid the odor from the kitchen as much as possible.

With some cases such treatment seems to have no effect whatever. These are the ones that draw upon our resources and test our ability to allay their suffering, and especially to keep their mental and nervous systems from running riot.

Cerium oxalate and bismuth, which by many are recommended so highly, I have found insufficient. They have never proved satisfactory, except in mild cases, and then when given in combination with cocaine. My experience has been similar with wine of ipecac, nux vomica, creosote, aconite, iodine, Fowler's solution, the bromides, and others, any one of which may be sufficient in mild cases. It is wise to change drugs occasionally to prevent habit or other deleterious effects. Of all the former, cerium oxalate, bismuth, and cocaine in small combination doses shortly before meals or before rising, give the best results. Quinine and cinchona juice, popoorn, light wines or whiskey (diluted)

taken moderately at intervals, may assist. Washing out the stomach gives but temporary relief.

I have obtained by far the best results from the following drugs in combination: Cocaine, resorcine, atropine, nitroglycerin, and morphine. The cocaine and resorcine act locally upon the stomach wall. The atropine tends to cut off all peripheral nerve endings, while the nitroglycerin acts upon the centres. The dose of each must be regulated according to the patient. One powder should be given with water from fifteen to twenty minutes before meals. If the patient is very bad I require her to lie quiet upon the right side for two hours after meals. The ice bag over the epigastrium, or a blister over the fourth or fifth dorsal vertebra, may relieve the symptoms.

The cervix should be examined for any ulceration, which, if present and properly treated, may relieve all trouble. Often a pessary, if properly applied, performs wonders. A tampon containing a one or two per cent. solution of cocaine placed against the end of the cervix may do the same, especially if the cervix has been kneaded between thumb and finger.

Should these measures fail, and the patient become weak, I put her to bed, give morphine with atropine hypodermatically in sufficient doses to control vomiting, requiring her to eat hearty meals. By paying attention to the bowels many may be carried in this way until the fourth month, when all symptoms often disappear like magic. If the vomiting does not abate the cervix should be dilated, even at the risk of a miscarriage resulting, which is not likely if carefully performed. Rectal feeding may be necessary to keep up the nourishment. If, however, in spite of every effort, the vomiting still persists, and the patient is very weak, with pulse over 120, possibly vomiting blood, and with some fever, it may be necessary to bring about a miscarriage. We should not wait so long as to endanger the life of the mother. Such cases, however, are rare. Yet they cross the path of the physician who has been long in practice, and his first duty as a medical man is to the mother.

*Dr. A. Ernest Gallant, of New York, states:*

The time at which vomiting usually appears is the third to fifth week of pregnancy; the nausea, with or without vomiting, on changing from the reclining to the upright posture, relieved by lying down; the similarity to the nausea induced by instrumental dilatation of the cervix without miscarriage; its cessation when the uterus has risen out of the pelvis and enlarged sufficiently to be supported by the pelvic brim; and the frequent failure of drugs to give relief until the uterus does emerge from the pelvic cavity; each and all confirm the view that the "morning sickness" of pregnancy is due to the increasing tension exercised on the internal os by the growth of the fetal sac, from within the uterus plus the additional weight brought about by the physiological congestion and increase in size of the uterus as a whole.

Treatment.—When the nausea is fresh it is preferable to place the patient in the left lateral Sims position, and carefully palpate the vagina with tampons or moistened cotton, applied in a manner of about median position, for ten or fifteen minutes.

The cessation of the nausea will confirm the diagnosis. After a few days the tampons may be discontinued and replaced by a hollow, soft rubber pessary, which may be left *in situ* for a month, if necessary, removed, cleaned, and replaced, or a new one inserted.

Whenever, in the vomiting of pregnancy, the external os uteri can be reached by the examining finger, the uterus should be lifted up and supported by tampons or pessary until it rises well above the superior straight. Should the vomiting continue later than the fourth month, if we add rest and quiet, posture, and diet, multiple incisions of the cervix or deliberate abortion will seldom or never be indicated.

Persistent vomiting of pregnancy is most frequently caused by displaced uterus, tubes, and ovaries, incarcerated in the pelvis, held by adhesions which prevent the uterus from emerging out of the pelvis, or weighted down by tumors, which sometimes cause the uterus to bulge at the vulva, and can be, in most instances, gradually released by placing the patient in the knee chest posture and introducing small tampons or gauze dipped in a mixture of ichthylol, two drachms, and glycerin, one ounce, and renewed every second or third day. Sometimes the uterus can be elevated in one or two sittings; occasionally the treatment will require a few weeks to accomplish its purpose. Under the solvent action of the ichthylol glycerin the adhesions soften and stretch, the organ is supported on the tampons, the tension is relieved, and the vomiting ceases, and even where miscarriage seemed inevitable a full term child has frequently been delivered. Under these circumstances patients must not be permitted to lie upon the back, but must be instructed to rest upon the side, or, better still, upon the abdomen, in order to facilitate the release of the impacted uterus. Most patients do better if kept quiet and at rest in bed. Should the nausea, vomiting, and backache continue after the fundus is above the brim, the abdomen must be supported by a tightly fitting binder or corset, put on while in the recumbent posture (*Journal of the American Medical Association*, xlviii, p. 1357, 1906). In no instance have we found it necessary to moderately dilate the cervix, as advised by Copeman.

General Measures.—The diet must be limited to fluid or semisolid, light and nourishing food, and at first it may be well to give nothing by mouth but six ounces of water every hour, until the stomach regains its normal status; sedatives in the form of sitz baths, moderate doses of bromide and chloral, avoiding opium preparations (unless a miscarriage is imminent, as they only upset the stomach the day after); counter irritants, mustard, blister, or cups over the epigastrium; mild laxatives, castor oil, licorice powder, at times olive oil or soap suds enema to insure free evacuation of the bowel twice daily.

In a limited number of cases, persistent vomiting, associated with pregnancy, may be due to malaria, kidney disease, acute or chronic gastritis, gastric ulcer, chronic appendicitis, typhoid fever, displaced kidney, anal fissure, gallduct disease, etc., each of which must be recognized and appropriate treatment applied.

*Dr. H. Tucker Lyons, of Brooklyn, N. Y., observes:*

In vomiting of pregnancy the resourcefulness of the physician will be taxed many times. Although we know that the aetiology may be sought in one of the three great avenues, viz., the gastrointestinal tract, pelvic deformities and injuries, and reflex irritation, still there remain many cases where the aetiology is in doubt or unknown.

In gastrointestinal catarrh due to a sluggish circulation, together with an impoverished condition of the blood and a torpid liver, the administration of fractional doses of calomel, or in a single dose of three grains, temporarily relieves the overburdened organs and allows appropriate treatment in time to become effective. Where there is a deficiency of the hydrochloric acid, as evidenced by delayed digestion, flatulence, etc., the administration of five to eight drops of the dilute hydrochloric acid three times a day, ten minutes after meals, will prove effective. Here the alkalies before meals, as the bismuth salts, magnesium and calcium carbonate, render valuable aid. If hepatic torpor is pronounced, sodium phosphate night and morning should be given, as well as sodium salicylate and the well known rhubarb and soda mixture.

Should flatulence be a prominent symptom drop doses of spirits of turpentine three times a day may be tried, or the preparations of salol and creosote carbonate. For the anæmia, which is so often a pronounced symptom, the various preparations of iron may be given, provided the bowels are active. Exercise in the open if possible should be insisted upon, for it is one of our best stimulants to the general well being that we possess. I have seen the judicious use of this treatment give most happy results. A glass of lukewarm water on arising will often allay the vomiting when medicinal agents fail. Of course a regulation of the diet must be insisted upon, otherwise our best efforts may prove fruitless. The preparations of codeine, cocaine, and drop doses of iodine tincture and dilute hydrocyanic acid should always be withheld to the last. In many cases of natural pelvic deformities we are actually helpless so far as the correction of the same is concerned. Here we must decide the momentous question, Can the patient be conducted to a safe motherhood? and if so act accordingly.

In the multiparous woman prolapse of the uterus, due to cystocele and rectrocele, with its train of symptoms, may be an aetiological factor; associated with the foregoing condition we may have a laceration of the cervix extending up into the broad ligament, with its constant pressure and irritation upon the uterine plexus, retroversions and retroflexions being freely coexistent. In the primipara a cystic ovary may be at the seat of the trouble or a uterine polyp, many of these patients presenting an endometritis of recent origin. The treatment for these cases is purely surgical.

Should the vomiting be unrelieved by any of these measures, the life of the patient in danger, we must deal with a pernicious state, the question of emptying the uterus presents itself. This procedure should be undertaken only after consultation with colleagues for the best interests of all concerned and for self protection.

## Therapeutical Notes.

**Treatment of Intestinal Hæmorrhage in Typhoid Fever.**—E. Hirtz and Cl. Simon, in *La Clinique* (November 29, 1907), advise the following procedure in the treatment of intestinal hæmorrhage, occurring in typhoid fever: Every two hours, or seven times during the day, give a teaspoonful of the following mixture:

B	Ergotine, .....	8.0 grammes;
	Calcium chloride, .....	6.0 grammes;
	Distilled water, .....	150.0 grammes.

M.

In the intervening hours administer one tablespoonful of a mixture made as follows:

B	Extract of opium, .....	0.10 gramme;
	Syrup of orange peel, .....	6.00 grammes;
	Syrup .....	140.0 grammes.

M.

Ice bags should be kept constantly applied to the abdomen.

**Nutritive Soup for Infants.**—In *Les Nouveaux remèdes* a formula for a nutritive soup is credited to Pierre Lesage. The soup is recommended in gastroenteritis, being well borne and readily taken by children of all ages. The soup is composed thus:

Potatoes, .....	60.0 grammes;
Carrots, .....	45.0 grammes;
Turnips, .....	15.0 grammes;
Green peas, .....	.....
Haricot peas, dried, .....	ââ 6.0 grammes.

These ingredients are added to one litre of cold water contained in a covered casserole or other porcelain vessel. Heat is applied and the mixture is allowed to boil for four hours. It is then strained to reject the peas and beans, and the volume is made up to one litre with boiling water. About 5 grammes of table salt is added for each 1,000 grammes of liquid. Infants to whom this soup is administered may do without milk for from two to eight hours.

**The Therapy of Gold.**—Professor Grasset (*Province médicale*) employs the double salt of gold and sodium (gold and sodium chloride) in the treatment of chronic rheumatism as follows:

B	Gold and sodium chloride, .....	0.10 gramme;
	Distilled water, .....	300.0 grammes.

M.

Professor Lemoine prescribes gold bromide in epilepsy, one or two teaspoonfuls of the following solution being ordered to be taken at night time:

B	Gold bromide, .....	0.20 gramme;
	Distilled water, .....	500.0 grammes.

M.

Gold bromide is also said to be efficacious in the treatment of cancer of the stomach and cancerous affections generally.

**The Uses of the Glycerophosphates.**—An editorial note in *The Prescriber* directs attention to the value of the glycerophosphates in gout, diabetes, phthisis, etc. It is shown that while they do not directly combat such maladies, they assist the vital powers. Combined with formates they form a useful tonic, the muscle-forming properties

of formic acid assisting the general process of building up. It is probable, remarks the writer, that the glycerophosphates act as foods to the nervous system, their good effects being most marked in nervous exhaustion from overwork. The salts most in use are sodium, potassium, calcium magnesium, and iron glycerophosphates, two or more of these usually being combined in solution with formates of sodium and potassium. Quinine glycerophosphate is usually given alone in doses of 3 to 8 grains in cachets.

**Powders for Inhalation in Asthma.**—Sawyer, in *Folia Therapeutica*, gives the following formulas for asthma powders:

I.

B	Potassii nitratis, .....	15.0 grammes;
	Pulveris anisi, .....	15.0 grammes;
	Pulveris stramonii, .....	30.0 grammes.

M. et fac pulverem.

Sig.: Ignite a thimbleful of the powder, and inhale as directed.

Mold with the fingers a thimbleful of this powder into a pyramid, place on a plate, and ignite at the pointed top. The plate should then be held near the patient's face and the fumes inhaled.

II.

B	Potassii nitratis, .....	15.0 grammes;
	Pulveris stramonii, .....	30.0 grammes;
	Pulveris anisi, .....	8.0 grammes;
	Pulveris lobelia, .....	4.0 grammes;
	Pulveris theæ sinensis nig. fol., .....	4.0 grammes;
	(Black tea leaves.)	

Olei eucalypti, .....

M. et fac pulverem.

Sig.: Ignite a small portion for inhalation, as directed.

III.

B	Potassii nitratis, .....	15.0 grammes;
	Sulphuris sublimati, .....	2.0 grammes;
	Pulveris anisi, .....	15.0 grammes;
	Pulveris stramonii, .....	30.0 grammes.

M. et fac pulverem.

Sig.: Ignite a small portion for inhalation, as directed.

When a pharmacy is not handy for the preparation of this prescription, "a mixture of one part by weight of saltpeter and two parts of black tea leaves, powdered and rubbed together, makes a good inhalant" in emergency cases.

**Picric Acid for Plantar Hyperidrosis.**—A 5 per cent. solution of picric acid in absolute alcohol applied with a swab of absorbent cotton on the end of a rod is effective in removing the pain, smell, and sweat of plantar hyperidrosis. Chandèze, who recommends this (*Journal de médecine, through The Practitioner*), advises if the feet are in very bad condition, the skin, thin, macerated, and bleeding, that the dressing should be done twice on the first day of treatment, and then once a day for three or four days.

**Enema in Gout Accompanied with Gastric Disorders.**—Milton (*Journal de médecine*) is credited with the following enema for use in the treatment of both acute and chronic gout in cases where medicine is not well borne by the stomach:

B	Starch water (5 per cent.), .....	1000 grammes;
	Infusure of colchicum root, .....	1.0 grammes;
	Wine of opium, .....	30 drops.

M.

The ink and mixture is used after dilution.

transportation through the mail as second class matter.

NEW YORK, SATURDAY, JANUARY 4, 1903

## THE COMMAND OF HOSPITAL SHIPS.

More than a year ago a joint board of army and navy medical officers was convened by executive order with instructions to prepare a plan for the unification of the medical services of the two arms to as great a degree as possible. This board recommended that hospital ships be put under the command of medical officers, a recommendation that received the approval of both the Secretary of War and the Secretary of the Navy. This recommendation was recently put into force by President Roosevelt, who, on the recommendation of the surgeon general of the navy, gave instructions that a surgeon be assigned to the command of the hospital ship *Relief*, which was about to go into commission. Coincidentally with the publication of this order, Rear Admiral Brownson, chief of the Bureau of Navigation, through which such orders pass, tendered his resignation, and it is understood that he did this as a protest against the appointment. The resignation has been accepted by the President, the appointment stands, and a statement by Surgeon General Rixey covering the matter has been made public, while Admiral Brownson's letter of resignation, which presumably presented the objections to the proposed order, has not been made public.

So far as we can ascertain, the objections which line officers in the service raise to the appointment is that it places in command of the vessel a man who in the nature of the case probably has no knowledge of navigation or seamanship, and who

therefore cannot accept the full responsibility for the welfare of the ship. This divided responsibility will, they say, not only be possibly disastrous in case of emergency, but will, they argue, require a complete revision of the rules of the service, all of which are based on the assumption that the commanding officer afloat is responsible for everything which occurs on board the ship. For instance, when through the laxity of a junior engineer officer the *Bennington* was blown up, the officer in command was court martialed. While this is the most cogent reason which has been advanced by the line of the navy against the placing of a medical officer in actual command, the warmth of feeling which has been developed in the matter and the acrimony with which the point is argued suggest the possibility that the officers of the line resent what they look upon as a gain of prestige on the part of the staff and a loss of prestige on the part of the line even more strongly than they condemn the proposed change from a purely theoretical point of view.

In the army this matter was definitely settled during the civil war when the policy was adopted of placing medical officers in command of hospitals and hospital ships and assigning a civilian crew and sailing master to such vessels. No instance has been cited where this practice proved objectionable. The very ship now involved, the *Relief*, formerly belonged to the army, and was commanded by a medical officer when used as a hospital ship. In the war with Russia the naval hospital ships of the Japanese were placed in command of medical officers, though when the war opened they had been in command of the officers of the line. It is said that one of the factors in determining this matter for the Japanese was a question as to the status of the hospital ship under the Geneva and Hague agreements. If such a ship were in command of a line officer and manned by a regular navy crew, circumstances might arise under which the peaceful status of the vessel might well be questioned. With a medical officer in actual command, such question could scarcely arise.

As a matter of fact, a hospital ship is merely a hospital afloat, and there is every reason why a hospital, whether afloat or ashore, should be under the immediate and actual command of a medical officer. None of the arguments which have so far been advanced in opposition to this plan will, we think, prove convincing to any person free from prejudice who gives the matter careful consideration in all its various phases. While it is to be regretted that this incident may cause a recrudescence of the ill feeling between the line and the staff, which has been allayed to a certain extent by the effect of the per-

sonnel bill, the arguments in favor of the change in policy seem to us to much outweigh those against it, and we congratulate the President and the Secretary of the Navy upon their firmness in carrying out a reform against such pronounced opposition on the part of the line officers.

### FALLING OF THE HAIR IN WOMEN.

An exceedingly sensible article on this important subject appears in the *Gazette de gynécologie* for December 1st. It is by Dr. R. Sabouraud, of the Hôpital Saint-Louis. M. Sabouraud says positively at the outset that the state of a woman's general health has nothing whatever to do with the loss of her hair, save for that which often follows an acute febrile disease; the falling of the hair is wholly due to an abnormal local condition characterized by overproduction of oily matter by the glands of the scalp, except of course in cases of a specific nature, which assume forms easily distinguished from the ordinary loss of hair.

The onset of baldness, as we all know, varies in the two sexes as a rule. In men the trouble begins at the crown of the head, though it may be supplemented by recession of the hair from the forehead; in women it is in the regions of the forehead and the temples that it is first conspicuous. The loss of hair usually sets in when the woman is between eighteen and twenty-two years of age, but it has long been preceded by indications that it is about to occur. At first dry pellicles form on the scalp, and they are somewhat difficult of removal; after a time these are succeeded by a yellowish greasy accumulation on the skin, and then the hair begins to fall. The loss may for a time be confined to the summer months, when the production of oily matter is more abundant than in winter.

The prime remedy for falling of the hair is the frequent removal of the greasy accumulation by the vigorous application of soap, and care must be taken that the soap employed does not contain enough potash to prove irritating. It is not the hair in its entire length that needs to be soaped, but only about five inches from the roots. After detritation of the scalp, the hair should be separated into plaits and the roots of each plait in succession, and particularly the portion of scalp concerned, rubbed vigorously with a tooth brush infused with soap and water. The solid cake of soap itself should not be applied, for then there would be left on the hair fine masses of soap which would serve only to collect dirt. After the soaping, the hair and scalp should be rinsed with warm water and dried with a soft towel, with the aid of gentle heat if necessary. The attempt must be made to correct

the resulting temporary dryness of the hair by means of oily applications.

The falling of the hair having thus been controlled, the growth of new hair may to a certain extent be stimulated, but the applications commonly employed, especially those of cantharides, should be avoided. There are a few substances which are reputed to have some effect in stimulating the growth of hair. Among them are pilocarpine, quinine, caffeine, and camphor, to any of which some perfume which is agreeable to the patient may be added. The author suggests the following formula, though he remarks that the proportions of the ingredients should be varied to suit individual cases:

R Pilocarpine hydrochloride, .....gr. iiij;  
Water, sufficient to dissolve the pilocarpine;  
Spirit of lavender, .....fl. 5v;  
Ether, .....fl. 5v;  
Ammonia water, .....fl. 5ss;  
Alcohol, sufficient to make, .....fl. 3viii

M.

When a woman finds that a particular prescription proves beneficial in her case, the author remarks, she is very apt, in the goodness of her heart, to pass it around among her friends, but disappointment is almost sure to result, because hardly any two cases in the circle of her acquaintances are exactly alike, and it would be as futile to order one prescription for indiscriminate use as to prescribe the same eyeglasses for all persons with visual errors.

### VIVISECTION IN THE STATE OF NEW YORK.

Promoters of legislation purporting to be in the interest of the moral and the humane are prone to show more zeal than discretion and to close their eyes to certain grave evils likely to result from the enforcement of the measures which they advocate. It was in deprecation of this tendency that in our issue for October 20th, commenting on an expected attempt to hamper the work of the Rockefeller Institute, we said: "It is well known to our readers that we have always condemned cruelty in experiments on animals, and we are quite ready to oppose the needless repetition of experiments undertaken simply for the purpose of demonstrating anew such facts as have been abundantly proved. We do not mention the subject of an animal to discomfit, to say nothing of actual suffering, for mere show purposes. But we do insistently advocate noninterference with the full liberty of vivisection done in the interest of real research, always, of course, with the understanding that the experiments shall be conducted with the most scrupulous avoidance of cruelty, and be entirely without the infliction of unnecessary pain or harm." While we still hold to

this view, we are willing to admit that a proper regard for the humane feelings of all right minded persons would naturally lead to the substitution, to a reasonable extent, of legal regulation for individual discretion.

It is quite probable that the radical antivivisectionists, unrestrained by really humane considerations, will press upon the legislature of the State of New York at its present session certain drastic enactments that would tend powerfully to retard the progress of medicine in the State, but we are glad to be able to add that a number of humane persons have drafted a bill to which we can give our cordial approval. It is entitled An Act to Prevent Cruelty by Regulating Experiments on Living Animals. It restricts experiments on living vertebrate animals to those authorized by responsible persons—that is, representatives of institutions, such as colleges and hospitals, qualified by their character to grant such authorization, or of the State or city. It confines the experiments to licensed places. It prescribes conditions which will tend to reduce the infliction of pain to the smallest amount made necessary by the demands of science, but will not interfere with an experiment seriously undertaken for scientific purposes. It requires reports to be made to the commissioner of health regarding such experiments as are performed. In this synopsis of the provisions of the bill we have employed very largely the words of one of the chief promoters of the bill, a man whom we believe to be actuated by entirely worthy motives and wholly free from any desire to hamper legitimate scientific investigation.

It is known to us that this bill has met with the endorsement of many representative members of the medical profession in the State, and we hope that the legislature will see the wisdom of giving it the preference over certain mischievous measures that are almost sure to be brought before it, and we trust that, in furtherance of this end, our New York State readers will exert their influence in favor of the bill upon the legislators representing them.

#### STUDIES CONCERNING CHLOROFORM ANÆSTHESIA.

On former occasions we have referred in these columns to the work of Buckmaster and Gardner in connection with chloroform anæsthesia (*New York Medical Journal*, February 2d and September 7th). In the *Proceedings of the Royal Society* for November 18th, their papers are continued. One communication deals with the rate of the absorption of chloroform by the blood during anæsthesia, another treats of the functions of the red blood corpuscles in chloroform anæsthesia, and the third re-

lates to the rate of elimination of chloroform. It was found that the chloroform contained in the blood rose in the initial stages of the anæsthesia with great rapidity to an amount which approached a maximum. During this period the chloroform appears to affect the respiratory centres so that breathing becomes slower and often ceases during the first few minutes of the anæsthesia. If the animal successfully passes this stage of the anæsthesia, on continuing the administration the amount of chloroform again rises toward the maximum. Then an equilibrium is maintained between the amount of intake and output of the chloroform. This equilibrium may be maintained for a considerable length of time, but the margin between it and death is very minute, and the condition is dangerous. The authors insist that chloroform kills by failure of the respiration, succeeded by asphyxia. They have never noticed a death by heart failure.

They find that chloroform is carried from the lungs to the cerebral centres by the red blood corpuscles, and that the percentage of chloroform in the blood does not suffer any variation corresponding to differences in the volume of the circulating blood. The rate of elimination of chloroform is at first comparatively rapid and subsequently slower. This is quite in accord with the facts known about the elimination of other substances from the body. When the blood contains a relatively high percentage of material to be eliminated the rate of excretion is naturally more rapid than when there is a smaller quantity in the circulating fluids. The elimination of chloroform is, however, a much less rapid process than its absorption.

#### SPURIOUS HENBANE.

Dr. A. B. Lyons, in a recent issue of the *American Druggist*, directs attention to the appearance in the American market of a variety of hyoscyamus which contains practically no hyoscyne, but does contain 0.8 per cent. of hyoscyamine, or approximately ten times the total alkaloidal contents of the pharmacopœial drug, which is derived from *Hyoscyamus niger*. It is important to guard against the substitution of this drug for the official one, both on account of its greater potency and by reason of the difference in the character of the effects produced. Since the *Pharmacopœia* standardizes the preparations of the drug on the basis of total contents of alkaloids, the substitution of the spurious henbane would not probably be discovered save in the difference in the therapeutic effect. Dr. Lyons says that the new drug is probably derived from *Hyoscyamus muticus*, which is used in the Orient under the name of *blang*, or *hasheesh*, and is sometimes used

in conjunction with cannabis indica, which is also known by the same names. From its effects it was formerly known as *Hyoscyamus inasus*, and is still called "sakin" (drunken) in Egypt.

### DANGER FROM BROMOFORM.

It appears that the use of bromoform as a remedy for whooping cough is not so free from danger as has been supposed. Löbl (*Wiener klinische Wochenschrift*, 1907, No. 19; *Berliner klinische Wochenschrift*, October 28th) reports a number of cases in which severe symptoms of poisoning occurred, although the usual dose was exceeded by only a few drops. Unfortunately, he says, the poisonous dose cannot be definitely stated, for individual susceptibility is very variable.

### News Items.

**The Geneva, N. Y., Medical Society** held its annual meeting on January 2d, and elected officers for the ensuing year.

**Association of Military Surgeons.**—The seventeenth annual meeting of this association will be held in Atlanta, Ga., on October 7 to 9, 1908.

**A State Sanatorium for the Treatment of Tuberculosis** is to be established in North Carolina. The State has made an appropriation of \$35,000, and the work will be started at once.

**The Manhattan Clinical Society** held a meeting on Friday, December 27th. The paper of the evening was read by Dr. Thomas F. Reilly on Some Observations on Grecco's Sign in Pleurisy with Effusion.

**A Research Laboratory** has recently been established in Tananarivo, Madagascar. In addition to scientific research work, the laboratory will be used for the analysis of foodstuffs and for other practical purposes.

**Charitable Bequests.**—By the will of Mrs. Louisa M. Bodine, the Kentucky Antituberculosis Association will receive \$20,000, and the Children's Free Hospital and the Children's Infirmary, Louisville, will each receive \$1,000.

**The Queens-Nassau Medical Society.**—The semi-annual meeting of this society, which was to have been held on Saturday evening, December 14th, has been postponed till Saturday, January 11th, when the same programme will be presented.

**The Internes of the Mount Sinai Hospital of Philadelphia** have formed the Alumni Association of the Hospital. Dr. George Rosenbaum is the president, Dr. D. M. Toll is the vice president, and Dr. M. B. Cooperman is the secretary and treasurer.

**Buffalo Medical Union.**—At the regular meeting of the union, held on December 18th, officers for the ensuing year were elected as follows: President, Dr. Vertner Kenerson; vice president, Dr. Edward J. Meyer; secretary and treasurer, Dr. C. B. Macdonald.

**Infectious Diseases in Chicago.**—During the week ending December 27th, 1907, there were reported 1,077 cases of infectious diseases, as follows: Typhoid fever, 10; scarlet fever, 10; diphtheria, 10; measles, 10; whooping cough, 10; pneumonia, 10; influenza, 10; tuberculosis, 10; syphilis, 10; gonorrhea, 10; skin diseases, 10; and other infectious diseases, 10. Total, 1,077.

**The Boston Society of Examining Physicians and Surgeons** will have its next meeting and dinner at the Hotel Somerset on Wednesday evening, January 8th. The meeting will be devoted to a discussion of life insurance examinations, and the principal speaker will be Dr. Augustus B. Knight of New York.

**Prince George County, Md., Medical Association.**—At the regular meeting of the association held in Hyattsville on December 14th, the following officers were elected:

President, Dr. John Cronmiller, of Laurel; vice president, Dr. Harry Nalley, of Brentwood; secretary, Dr. H. B. McDonnell, of College Park; treasurer, Dr. A. O. Etienne, of Berwyn.

**New Counsel for the Medical Society of the County of New York.**—Mr. Champe S. Andrews, who has been counsel to the society for the past seven years, has tendered his resignation, which has been accepted, to take effect on January 1st. It is understood that he is to be succeeded by Mr. Emery C. Weller and Mr. Philip C. McCook, who have been associated with Mr. Andrews.

**Vacation Lectures at the University of Berlin.**—The medical lectures during the coming vacation, held by the Lecturers' Association of the Medical Faculty of the Berlin University, will begin on March 2d and will close on March 28, 1908. A catalogue of the lectures will be sent free of charge by applying to Dr. Melzer, Langenbeck Haus, 10 and 11 Siegelstrasse, Berlin, Germany.

**Georgetown University Hospital.**—A department for the examination and treatment of patients suffering from tuberculosis has been opened at this hospital, in connection with the outdoor department. Dr. W. C. Gwynn has charge of the clinic, which meets every week on Monday from 11 to 12 a. m. A nurse from the Instructive Visiting Nurse Society visits patients at their homes to aid them in carrying out the physician's instructions.

**The New York Herter Lectures by Professor Starling.**—Dr. Ernest H. Starling, professor of physiology in the University of London, will give the Herter lectures of the year on the subject, *The Fluids of the Body*, beginning January 6th, at 4 p. m., and continuing daily at the same hour throughout the week, at the Carnegie Laboratory of the University and Bellevue Hospital Medical College, 338 East Twenty-sixth street. All interested are cordially invited to be present.

**The Seaboard Medical Association**, which is composed of physicians from the tidewater sections of Virginia and North Carolina, have elected the following officers for the year 1908: President, Dr. Armistead K. Tayloe, of Washington, N. C.; first vice presidents, Dr. E. C. S. Taliaferro, of Norfolk; Dr. B. F. Halsey, of Roper, N. C.; Dr. J. G. Woodward, of Norfolk; Dr. J. R. Harker, of Tyner, N. C.; treasurer, Dr. Israel Brown, of Norfolk; secretary, Dr. John R. Bagby, of Newport News.

**Obstetrical Society of Philadelphia.**—At the regular meeting of this society, held on Thursday evening, January 2d, Dr. Edward P. Davis showed a patient with an interesting dextroty. Dr. C. C. Norris and Dr. Charlotte B. Mitchell reported a case of primary ovarian pregnancy. Dr. Barton Cooke Hirst reported a case of abdominal pregnancy in which the ovum was implanted in the pelvic peritoneum, remote from the tubes and ovaries. He also exhibited a specimen of unusually large hydrosalpinx.

**Typhoid Fever in Porto Rico.**—We learn from press dispatches that an epidemic of typhoid fever has broken out in Caguas, Porto Rico. Governor Foster personally inspected the town and found one hundred and twenty-five cases. He has given orders to construct a temporary hospital in which to segregate the sick, and to disinfect or burn all houses where the fever has been found. All American school teachers have been ordered to leave the infected district. It is said that the outbreak is due to contaminated water.

**Dr. Robert Reyburn Honored.**—At the regular meeting of the Medical Alumni Society of Worcester, Mass., on January 2d, a silver loving cup was presented to Dr. Reyburn by the society, in appreciation of his fifty years of active practice. After routine business had been transacted, a literary and musical programme was presented. Dr. Reyburn read a paper entitled *The Prevention of Death During Anesthesia by Chloroform and Ether*, and Professor Kelly Miller delivered an address on the Allegiance of the Alumni to the Alma Mater.

**Gift to Union Hospital, Fall River, Mass.**—The Union Hospital, Fall River, Mass., has received a gift of \$1,000 from the Medical Alumni Society of Worcester, Mass. The gift was made in recognition of the services rendered by Dr. Robert Reyburn, who has been a member of the society for fifty years. The gift will be used to secure other contributions which were given conditionally.

contributions being that of \$45,000 by Mrs. Frank S. Stevens, of Swansea, \$10,000 by the late John D. Flint, and \$7,500 by M. C. D. Borden.

**Personal.**—Professor Simon Newcomb, of Washington, D. C., and Professor Emil Fischer, of Berlin, have been elected members of the Göttingen Academy of Sciences.

Dr. Frederick Montzambert, of Ottawa, Canada, and Dr. E. P. La Chapelle, of Laval University, Montreal, have been elected Fellows of the Royal Sanitary Institute.

Dr. Carl D. Camp, of Philadelphia, has been appointed clinical professor of nervous diseases in the University of Michigan, in the place made vacant by the death of Dr. William J. Herdman.

**An Operation for Appendicitis in Midocean.**—The Cunard liner *Pannonia*, while on her way from the Mediterranean to New York, was stopped for an hour in mid-ocean to permit the surgeons to perform an operation for appendicitis on a member of the crew. The operation was performed by Dr. J. Fraser Orr, ship surgeon, who was assisted by Dr. Torok, of the Hungarian Government. The sea was running very high and the vessel rolled badly, but the operation was entirely successful, although it took one hour to complete it.

**The General Practitioners' Medical Society, of Columbus, Ohio,** held a meeting on December 10th, and elected the following officers: President, Dr. Ida Wilson; vice president, Dr. S. O. Griffin; secretary and treasurer, Dr. A. B. Davenport. After the business meeting a banquet was held, at which addresses were made by Dr. C. F. Gilliam, Dr. Emma O. Jones, Dr. Fred O. Williams, Dr. E. A. Hamilton, and Dr. J. W. Clemmer. Dr. Wilson, the newly elected president, is also vice president of the Women's Medical Club of Columbus.

**Sydenham Hospital, New York.**—The following members of the medical board of this hospital resigned in a body on December 27th: Dr. Edwin Beer, Dr. Herman J. Boldt, Dr. C. G. Kerley, Dr. L. La Fetra, Dr. S. Oppenheimer, Dr. G. Seeligman, Dr. A. Strouse, and Dr. A. Wiener. The following adjuncts have also resigned in a body: Dr. Richard Weil, Dr. Richard Lewisohn, Dr. Arthur Stein, Dr. Joseph E. Field, Dr. De Witt Stetten, Dr. A. Richard Stern, and Dr. Ernst Danziger.

**Cortland County, N. Y., Medical Society.**—The annual meeting of this society was held on December 20th. Officers for the ensuing year were elected as follows: President, Dr. H. C. Hendrick, of McGaw; vice president, Dr. S. J. Sornberger, of Cortland; secretary, Dr. R. P. Higgins, of Cortland; treasurer, Dr. C. D. Ver Nooy, of Cortland. The retiring president, Dr. F. S. Jennings, delivered an address on Tendencies in Medicine. Dr. T. H. Halstead, of Syracuse, read a paper on Esophagotomy and Bronchotomy, and Dr. S. J. Sornberger read a paper on Some of the Reflex Neuroses.

**Scientific Society Meetings in Philadelphia for the Week Ending January 11, 1908.**—*Monday, January, 6th,* Philadelphia Academy of Surgery; Biological and Microscopical Section, Academy of Natural Sciences; West Philadelphia Medical Association; Northwestern Medical Society. *Tuesday, January 7th,* Academy of Natural Sciences; Philadelphia Medical Examiners' Association. *Wednesday, January 8th,* Philadelphia County Medical Society. *Thursday, January 9th,* Section Meeting Franklin Institute; Pathological Society. *Friday, January 10th,* West Branch, Philadelphia County Medical Society.

**The Philadelphia Neurological Society.**—At the regular meeting of this society, held on Monday evening, December 23d, Dr. Alfred Gordon reported a case in which the parietal lobe of the cerebrum was destroyed and in which there was a preservation of the stereognostic function. Dr. W. B. Cadwalader reported a case of segmental asteriognosis resulting from a lesion in the parietal area. Dr. Charles K. Mills and Dr. J. W. McConnell exhibited two cases. Dr. T. H. Weisenburg reported a case of ascending post-rolateral sclerosis. Dr. D. J. McCarthy reported a case of ascending paralysis. Dr. Lightner Witmer reported a case of a better knowledge of psychology. Dr. Walter S. Cornell read a paper on The Backward and Mentally Deficient Children in the Public Schools. Dr. S. D. Ludlum reported a case of degeneration in the periphery of the spinal cord.

**The Mortality of Chicago.**—According to the report of the Department of Health for the week ending December 21, 1907, there were during the week 592 deaths from all causes, as compared with 618 for the corresponding week last year. The annual death rate in 1,000 of population was 14.65. The principal causes of death were: Apoplexy, 8; Bright's disease, 37; bronchitis, 22; consumption, 72; cancer, 26; convulsions, 5; diphtheria, 12; heart diseases, 49; influenza, 4; intestinal diseases, acute, 20; measles, 6; nervous diseases, 15; pneumonia, 92; scarlet fever, 13; suicide, 10; typhoid fever, 10; violence (other than suicide), 48; whooping cough, 1; all other causes, 142.

**National Association for the Study and Prevention of Tuberculosis.**—The fourth annual meeting of this association will be held in Chicago on June 5 and 6, 1908. The organization of the sections has been arranged as follows: Sociological Section: Mr. Ernest P. Bicknell, of Chicago, chairman; Mr. Alexander M. Wilson, of Chicago, secretary; Clinical and Climatological Section: Dr. Henry Sewall, of Denver, chairman, and Dr. H. W. Hoagland, of Colorado Springs, secretary; Pathological and Bacteriological Section: Dr. L. Hektoen, of Chicago, chairman; Surgical Section: Dr. A. E. Halstead, of Chicago, secretary; Section in Tuberculosis in Children: Dr. William F. Cheney, of San Francisco, chairman.

**Training in Medical Organization.**—The students of the University of Pennsylvania Medical School have formed an organization, the purpose of which is to acquaint the undergraduates with the workings of the American Medical Association, after which it is very closely modeled. The various student societies take the place of the State organizations and elect members to a house of delegates which transacts all the business of the association. An annual meeting is held, at which papers are read by chosen members, thus encouraging original research and a scientific spirit. The organization is named The Undergraduate Medical Association of the University of Pennsylvania and already has over two hundred and fifty members.

#### Infectious Diseases in New York:

*We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending December 28, 1907:*

	December 21-28.		December 23-30.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever	35	12	42	18
Smallpox	3	..	2	..
Varicella	108	..	123	..

**Quarantine Work of the Public Health and Marine Hospital Service.**—The Public Health and Marine Hospital Service last year inspected 4,635 vessels, of which 478 were disinfected at the forty-three national quarantine stations in continental United States. Inspection has been maintained on both the Canadian and the Mexican borders. A train inspection service was maintained during the year to prevent the introduction of smallpox into the State of Maine from New Brunswick and Nova Scotia, where it prevailed in epidemic form. National quarantine has also been maintained at eight ports in Porto Rico, seven in Hawaii, and seven in the Philippines. During the fiscal year 1,285,349 immigrants were inspected under the provisions of the immigration laws and regulations.

**The Health of Pittsburgh.**—During the week ending December 14, 1907, the following cases of transmissible diseases were reported to the Bureau of Health of Pittsburgh: Chickenpox, 16 cases, 0 deaths; typhoid fever, 112 cases, 17 deaths; scarlet fever, 20 cases, 1 death; diphtheria, 12 cases, 1 death; measles, 68 cases, 4 deaths; whooping cough, 8 cases, 1 death; pulmonary tuberculosis, 20 cases, 0 deaths. The total deaths for the week numbered 155 in an estimated population of 403,330, corresponding to an annual death rate of 19.08 per 1,000 population. During October there were 567 deaths from all causes in Pittsburgh, corresponding to an annual death rate of 15.24 per 1,000 population for the month.

**Popular Medical Lectures at Harvard.**—A course of free public lectures has been arranged by the Faculty of Medicine of Harvard University, which will be held in the new buildings of the medical school, Longwood avenue, Boston, on January 4th at 8 p. m. and Sundays at 4 p. m. beginning January 4th and ending April 26th. No tickets required. The lecture on January 4th will be delivered by Dr. Walter B. Cannon on Recent Discoveries in the Physiology of Digestion; on January 5th, Dr. Edward H. Bradford will deliver a lecture on the Human Gait; the January 11th lecture will be delivered by Dr. Elliott P. Joslin on the Modern Crusade against Typhoid Fever, and the lecture on January 12th will be on Common Salt, by Dr. Lawrence J. Henderson.

**Southern Surgical and Gynecological Association.**—The twentieth annual meeting of this association was held in New Orleans on December 17th to 19th, and it is said that the meeting was one of the largest and most successful in the history of the organization. The following officers were elected: President, Dr. F. W. Farham, of New Orleans; first vice president, Dr. Willis F. Westmoreland, of Atlanta; second vice president, Dr. Henry D. Fry, of Washington, D. C.; secretary (reelected), Dr. William D. Haggard, of Nashville; treasurer, Dr. Stuart McGuire, of Richmond; council, Dr. George Ben Johnson, of Richmond; Dr. Richard Douglas, of Nashville; Dr. Howard A. Kelly, of Baltimore; Dr. Lewis A. McMurtry, of Louisville, and Dr. George H. Noble, of Atlanta. The next meeting will be held in St. Louis.

**The Fifth Pan American Medical Congress** will be held in Guatemala, Central America, the second week in August, 1908. Guatemala is situated on an elevated plateau which is comparatively cool, and the weather will probably not be uncomfortable. The trip from New Orleans or from New York by steamer to Porto Barrios is an agreeable one. The arrangements for the trip will be in the hands of the chairman of the committee on transportation. There will be no charges for transportation within the Republic of Guatemala. The Government and the people of Guatemala are taking an active interest in the meeting, and are doing everything in their power to make it a great success. Further information regarding the congress can be obtained from Dr. Ramon Gutierrez, 75 West Fifty-fifth street, New York, who is the secretary of the International Executive Committee.

**The Health of Philadelphia.**—During the week ending December 14, 1907, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Typhoid fever, 76 cases, 8 deaths; scarlet fever, 50 cases, 5 deaths; chickenpox, 73 cases, 0 deaths; diphtheria, 93 cases, 14 deaths; cerebrospinal meningitis, 3 cases, 1 death; measles, 34 cases, 1 death; whooping cough, 15 cases, 5 deaths; pulmonary tuberculosis, 87 cases, 53 deaths; pneumonia, 84 cases, 66 deaths; erysipelas, 6 cases, 2 deaths; septicaemia, 1 case, 0 death; diphtheria, 1 case, 0 death; German measles, 2 cases, 0 deaths; scarlet, 24 cases, 28 deaths. The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 13; puerperal fever, 2; dysentery, 1; diphtheria and scarlet, and two cases of age 11. The total deaths numbered 568 in an estimated population of 1,300,505, corresponding to an annual death rate of 19.61 in 1,000 population. The total infant mortality was 112; under one year of age, 109, between one and two years 13. There were 37 still births, 10 males, and 18 females. The total population was 2,177 males.

**Philadelphia Bureau of Health Statistics.**—During the month of October, in the Division of Medical Inspection 3,702 inspections were made, exclusive of schools; 636 of these were ordered, 18 cases were referred for special diagnosis, 1,068 were sent back to the schools, and 567 children were excluded from entering with school certificates. In the Division of Child Hygiene, 1,871 inspections were made, 1,041 of these were referred for special diagnosis, and 1,000 children were sent back to the schools. In the Division of Milk Inspection 1,068 inspections were made of milk at points of sale, of which 778 quart cans, 2,000 3-gallon cans, 1,000 half-gallon cans, and 1,068 quart cans were found to be satisfactory. In the Division of Meat and Cattle Inspection 1,767 inspections were made of which 1,000 were found satisfactory, 447 poor, and 320 diseased meat were condemned. 170 meat stores and 100 markets were made satisfactory. In the Division of Dairy Inspection 1,000 inspections were made, of which 1,000

let fever; 326 for diphtheria; 89 for typhoid fever; 172 for tuberculosis; 142 for miscellaneous diseases, and 34 schools were fumigated. In the Bacteriological Laboratory 1,104 cultures were examined for the presence of bacillus diphtheriae; 363 specimens of blood were examined for the serum diagnosis of typhoid fever; 1,083 specimens of milk were examined; 149 specimens of sputum were examined; 7 disinfection tests were made, and 3,983,600 units of antitoxine were distributed. In the Chemical Laboratory 147 analyses were made.

### Society Meetings for the Coming Week:

MONDAY, January 6th.—German Medical Society of the City of New York; Utica, N. Y., Medical Library Association; Niagara Falls, N. Y., Academy of Medicine; Practitioners' Club, Newark, N. J.; Hartford, Conn., Medical Society.

**TUESDAY, January 7th.**—New York Academy of Medicine (Section in Ophthalmology); New York Morphological Society (annual); Buffalo Academy of Medicine (Section in Surgery); Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson County, N. J., Medical Association (Jersey City); Medical Association of Troy and Vicinity (annual); Hornellsville, N. Y., Medical and Surgical Association; Long Island, N. Y., Medical Society; Bridgeport, Conn., Medical Association.

WEDNESDAY, January 8th.—New York Pathological Society (annual); New York Surgical Society; Medical Society of the Borough of the Bronx, New York; Alumni Association of the City (Charity) Hospital, New York; Brooklyn Medical and Pharmaceutical Association (annual); Richmond County, N. Y., Medical Society (annual).

THURSDAY, January 9th.—New York Academy of Medicine (Section in Pædiatrics); Brooklyn Pathological Society; Blackwell Medical Society of Rochester, N. Y. (annual); Jenkins Medical Association, Yonkers, N. Y.

FRIDAY, January 10th.—New York Academy of Medicine (Section in Otology); New York Academy of Medicine (Section in Surgery); New York Society of Dermatology and Genitourinary Surgery; Eastern Medical Society of the City of New York; Saratoga Springs, N. Y., Medical Society.

SATURDAY, *January 11th.*—Therapeutic Club, New York.

**The New York Academy of Medicine.**—A stated meeting of the academy, under the auspices of the Section in Pædiatrics, was held on Thursday evening, January 2d. The following papers on Tuberculosis in Infants and Children were read: The Pathological Findings, by Dr. John McCrae, of Montreal; Recent Diagnostic Methods, by Dr. W. H. Park, of New York; Laboratory Aids to Diagnosis, by Dr. T. Homer Coffin, of New York; Channels of Communication, Their Relative Significance, by Dr. S. McC. Hamill, of Philadelphia; Management and Treatment, by Dr. Lovett Morse, of Boston.

The Section in Dermatology will meet on Thursday evening, January 7th. After the presentation of cases, an executive session will be held.

The Section in Otology will meet on Friday evening, January 10th. The paper of the evening will be read by Dr. B. Alexander Randall, of Philadelphia, on Do Certain Ear Diseases Tend to Lateralize to the Right or Left Side? An executive session will be held.

The Section in Surgery will meet on Friday evening, January 10th. Dr. John F. Erdmann will present a patient with a four ounce brain tumor, Dr. A. Ernest Gallant will present a case of ureteral drainage through the vagina, and Dr. A. A. Berg will present six kidney cases showing some unusual features. A paper, entitled *Some Observations on the Surgical Treatment of the Kidney and Ureter*, by Dr. F. Brewer, Dr. Fielding L. Taylor will report a case of abscess of the frontal lobe, and Dr. Joseph Wiener will report three cases of unilateral hemorrhagic nephritis.

## Pith of Current Literature.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL.

December 26, 1907.

1. The Attitude of the Medical Profession toward the Psychotherapeutical Movement. By E. W. TAYLOR.
2. The Use of X Ray Examinations in Pulmonary Tuberculosis. By FRANCIS H. WILLIAMS.
3. The Results of the Chemical Investigation of Tumors. By S. P. BEEBE.
4. The "Optometrist." A Warning Word. By JOHN C. BOSSIDY.
5. Strain as a Causative Factor in Infectious Arthritis. By JOHN D. ADAMS.

#### 1. The Attitude of the Medical Profession Toward the Psychotherapeutical Movement.

Taylor reviews the past and future of this treatment, and remarks that the comprehensive knowledge of the movement, as it exists in the medical profession would best be disseminated by taking the laity into the confidence of the profession through popular lectures and the press. He concludes that in our enthusiasm for the development of a highly significant therapeutic advance we should not allow the traditions of the profession to which we belong to be submerged. Our enthusiasm should not lead to the antagonism of any reasonable member of the profession. In our efforts toward what we regard as progress we should proceed with great deliberation and by recognized logical methods. To this end we should quote cases and exploit methods which have stood the test of experience. We should hesitate in appearing before the public with a detailed expression of our views and theories until we have secured the acquiescence of the conservative members of our own profession. We should not ally ourselves with movements over which we have no immediate control; we can ill afford misinterpretation, especially at the hands of our brother physicians. Our essential aim should be to develop a permanent interest in the psychotherapeutical movement within the ranks of the profession, and to do nothing which can in any way retard this effort. To this end we should urge reasonable but adequate recognition of the assertions of psychotherapy as a legitimate and necessary element in medical education. Finally, our one object as members of a liberal profession should be to insist upon the importance of psychotherapeutical methods with an enthusiasm which should only be increased by the legitimate limitations set upon its action.

5. Strain as a Causative Factor in Infectious Arthritis.—Adams reports several such cases, an analysis of which shows many common factors, namely, vocation, seat of disease, sequence of joints attacked, symptoms, and relief by treatment. In considering vocation as a factor one must not only analyze the character of the work but also the conditions under which it is done. Careful investigation showed that all these patients were tailors working in dry, well ventilated rooms, not exposed to drafts and in an even temperature. Their work, ten hours a day, was chiefly on heavy goods, mostly men's clothes. The symptoms were first noted in the thumb finger, and the histories showed a progressive infection of the joints in the right hand before any symptoms occurred in the left. The onset was rapid, and the pain and symptoms not

especially acute, but in all the cases, intensified greatly with use. The pain, intermittent in character, was more in the nature of a soreness rather than the throbbing pain of an infection. The symptoms were not affected to any extent by sudden changes of temperature. In all the cases there was absolutely no indication of any trouble in any other joint in the body. In other words, the trouble was absolutely confined to the hands. The problem confronting one in these cases is a serious one, as we have a patient otherwise perfectly well but incapacitated for making her daily bread. Such a condition of affairs brings about the most pronounced type of mental depression. The following line of treatment was pursued in all the cases: Urinary examination showed a marked hyperacidity in all the cases. General treatment, omitting all meats, forcing liquids; sodium benzoate, gr. v, t. i. d., to neutralize acidity. Local treatment, baking daily. This was done entirely by electricity. In the more acute cases a very intense heat was used, namely, a 100 candle power light, applied for a period of twenty minutes, close enough to be tolerated by patient over bare skin. In other cases, a small wooden box, one foot square, was made with two small apertures, large enough to insert hands, in one end. The box was lined with asbestos to prevent radiation, and fitted up with six 16 candle power incandescent lights. A temperature of 300 degrees F. was maintained here for a period of twenty minutes. The results were most gratifying. The counter irritation of the heat produced the usual hyperæmia to a marked degree, and all the cases showed a gradual diminution of pain, with a return on failure in systematic baking. The patients pursuing the treatment conscientiously for two months had entire relief from pain, with ability to return to work.

### THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

December 28, 1907.

1. Brain Tumor with Jacksonian Spasm and Unilateral Paralysis of the Vocal Cord and Late Hemiparesis and Astereognosis. By JOHN L. ATLEE and CHARLES K. MILLS.
2. Tubal Twin Pregnancy. By CHARLES G. CHILD.
3. Diverticulum of the Vermiform Appendix. By ISABELLA C. HERB.
4. Pathophysiology and Therapeutics. By GEORGE F. BUTLER.
5. Clinical Observations in the Acute Infectious Diseases. By LOUIS FISCHER.
6. Phlegmonous Gastritis. A Report of Two Cases. By H. E. ROBERTSON.
7. Ossiculectomy in Chronic Middle Ear Suppuration. By FREDERICK L. JACK.
8. The Paravertebral Triangle of Dullness in Subphrenic Abscess (Grocco's Sign). By K. HEDERDEN BEALL.

2. Tubal Twin Pregnancy.—Child reminds us that there are recognized two varieties of multiple extrauterine gestation, where the pregnancy is tubal. In order to distinguish these two varieties they may be classified as follows: 1. Twin tubal pregnancy, where each tube contains an ovum. 2. Tubal twin pregnancy, where one tube contains both ova. Of the first variety, generally considered to be the rarer of the two, several cases are reported. Of the second variety he has been able to find but five reported cases, to which he adds a sixth case. The abdomen was opened through the median line in-

cision; when it, as well as the pelvic cavity, was found to contain a great quantity of fluid and clotted blood; the left tube was ruptured in three places, a segment two inches in diameter lying free in the blood clot. Twin fetuses lay outside of the tube, one attached by its umbilical cord, the other free. The proximal end of the tube was bleeding profusely, the distal end was densely adherent to the ovary, but showed no active bleeding. The tube and ovary were ligated and removed. The right tube was intact and adherent to the ovary and posterior face of the broad ligament. The peritoneal cavity was cleared of blood and clots, the wound closed, and the patient given an infusion of physiological salt. Death followed twelve hours later, with gradually rising temperature and pulse.

### 3. Diverticulum of the Vermiform Appendix.

—Herb describes her case and thinks that the attack of appendicitis eighteen years ago was responsible for the condition found. The fibrous connective tissue capsule with deposits of lime salts showed it was not of recent origin. It is possible that the occlusion occurred at that time; however, the character of the tissue forming the septum where the appendix was occluded rather precludes the possibility of its being as old as the connective tissue capsule of the diverticulum. The glands still retaining their functioning power to some extent, their secretion by pressure produced a diverticulum through the muscle undermined by the inflammation, or enlarged preexisting one. That the author was not dealing with a dermoid cyst was proved by the absence of epiblastic structures. The character of the wall as well as the content—no hooklets or scolices being found—indicated it was not an hydatid cyst. Enteric cysts extend into the bowel lumen and rarely, if ever, pass through the muscular coats; they are formed by the occlusion of the glands of Lieberkühn and do not communicate with the intestinal lumen. Mesenteric cysts can be excluded, as the diverticulum was situated on the free border; many mesenteric cysts, however, are intestinal diverticula, with a constricted base. The possibility of the diverticulum being an implantation cyst is also to be excluded, as the ovarian cyst was a simple, benign, unilocular cystoma without adhesions and a fluid content changed to a greenish yellow by hemorrhage occasioned by the pedicle being twisted. Cystic malignant disease is excluded for obvious reasons.

5. Clinical Observations in the Acute Infectious Diseases.—Louis Fischer, of New York, says he is convinced that an extra careful diet and absolute supervision, with the aid of a trained nurse, if possible, will do more good than all medication combined. The walking convalescent with a weak heart and low digestive power who is permitted meat and cake or unwholesome food of any sort usually invites infection, and thus complication commences. The desquamation of the skin permits easy chilling of the surface of the body. In like manner the high fever produces a marked subnormal condition. Pathogenic bacteria remain dormant in the nose and throat and in the general circulation, and these require but one of the factors just mentioned to begin an active inflammatory process. It is wiser to keep a child one week longer in bed and two if necessary, than the customary four or

six weeks, rather than be accused of carelessness and perhaps cause a fatal termination by a complication.

6. Phlegmonous Gastritis.—Robertson observes that phlegmonous gastritis is a rare form of gastric inflammation characterized by a diffuse or focal infiltration of the stomach wall by pus and serum. It is caused by the entrance into the submucosa of a virulent organism, usually the streptococcus, through some defect in the gastric mucosa, though cases are reported in which no defect could be found. It occurs more commonly in day laborers of the alcoholic type and at or past middle life. The clinical symptoms are vomiting, thirst, pain and tenderness in the epigastrium, fever, rapid pulse, signs of peritonitis, collapse, and death. The duration is from twenty-four hours to fourteen days, and the average is from four to six days. The diagnosis is usually made at autopsy only. The prognosis is extremely grave and treatment is of little avail. Post mortem examination frequently shows, besides the stomach condition, purulent peritonitis, and other associated lesions. Bacteriological examination usually yields the streptococcus in pure culture.

7. Ossiculectomy in Chronic Middle Ear Suppuration.—Jack thinks that between 9 and 10 per cent. of neglected cases of chronic middle ear suppuration sooner or later developed symptoms demanding surgical interference. Thorough medical treatment is first to be tried in all cases, excepting patients having symptoms of intracranial or mastoid involvements. The result of ossiculectomy has proved satisfactory in many cases. This operation avoids some of the dangers of the radical operation. Curettement of the eustachian tube is of great value in preventing reinfection of the middle ear cavity. The mortality of ossiculectomy is practically nil.

### MEDICAL RECORD.

December 28, 1907.

1. Some Unclassified Dangers in Anæsthesia, By JOSEPH D. BRYANT.
2. Environment and Personal Hygiene as Causes of Consumption, By RICHARD COLE NEWTON.

5. Hot Springs, Virginia, By GUY HINSDALE.
6. Appendicitis Due to the Presence of *Campylobacter* *jejuni*, By M. CLAYTON THURMOND.
3. The Bacteria as Incitants of Malignant Endocarditis.—Wadsworth states that malignant endocarditis develops on the injured or diseased endocardium as a secondary localization in the bacteræmia or pyæmia of infectious disease. It may be incited by many different species of bacteria, but usually the pneumococcus, streptococcus, staphylococcus, or gonococcus is present. It may be associated with any of the infectious diseases of man, but chiefly with pneumonia or some form of sepsis. As a complication of previous disease, malignant endocarditis is of so serious a nature and so often mortally or dominates the parent infection that separate consideration of it is justified. The exceptionally grave tenor of the prognosis is due to the anatomical situation of the lesion. The experimental studies of Rosenbach, Wyss-Koch, and others have demonstrated the importance of previous infection

the endocardium in determining the secondary localization of the infection in the heart, a fact of definite practical significance to both surgeon and physician in the prophylaxis of the disease. This study has also shown that the lesions of the endocardium once freed of their mycotic nature tend to heal, and thus recovery, when it occurs, differs in no essential from that of infection in general, a fact as yet of little practical value owing to the inadequacy of present methods of specific treatment in bacteriæmic disease. Apart from accidents of infarction or thrombosis, the course, the prognosis, and the treatment of malignant endocarditis, as of infection in other parts of the body, depend primarily upon the balance between the two opposing factors of infection, the body cells and the bacterial cells. In this complex mechanism of infection the different processes of immunity in the body tissues, on the one hand, and on the other the development of the bacteria, their susceptibility, and virulence, vary in their relation one to the other with different bacterial species and under different conditions. Since the control of these subtle conditions is beyond the reach of modern therapy, the manifestations of the disease, even the elevation of temperature, are to be regarded in general as indicative of the effort of the body tissues to maintain a favorable balance. The limitations of rational treatment are thus apparent, and departure from a rigid, conservative, personal, or physiological hygiene is sanctioned only under exceptional conditions arising in the individual cases.

**6. Appendicitis Due to the Presence of *Oxyuris Vermicularis*.**—Thrush describes such a case. He removed the appendix, which had all the appearance of an acute infection with marked congestion of the bloodvessels, the only peculiar feature being a bulb like expansion of the tip into a mass about one inch long and about double the caliber of the remainder of the organ. On incising the appendix it was found that this mass consisted of a thick mucoid substance, with a constriction separating it almost completely from the appendiceal canal, and in this jelly like substance was a large number of worms of various sizes of development, and moving around freely. Some were quite small, others of full development. Altogether there were about one hundred of these worms. Microscopical examination confirmed the diagnosis of the *Oxyuris vermicularis* as being the variety of worm observed. Rectal examination of the patient showed, as was expected, an abundance of these worms present. They had spread far up into the colon until they reached the region of the appendix, where some of the ova became imprisoned and developmental changes occurred, causing the attack. The patient made an uneventful recovery.

By F. P. MACKIE.
5. A Possible Explanation of Late Return Cases in Scarlet Fever.  
By W. HABGOOD.

**4. Relapsing Fever and Lice.**—Mackie investigated an outbreak of relapsing fever, occurring in Bombay, and summarizes the results of his observations as follows: 1. An epidemic of relapsing fever broke out in a mixed settlement of boys and girls living under similar conditions. 2. A very high percentage of the boys fell victims to the disease in the course of a few weeks. 3. A much smaller percentage of girls fell ill and at infrequent intervals, extending over three months. 4. The most notable factor in which the boys differed from the girls was that they were infested with body lice, from which parasite the girls were almost free. 5. A well marked percentage of the lice taken from the infected ward contained living and multiplying spirilla. 6. The stomach of the louse was the chief seat of multiplication, and this was carried on in the face of active digestion and after the disappearance of all other cellular elements. Other organs become secondarily infected. The secretion expressed from the mouth of infected lice contained numbers of living spirilla, and they also existed in greater or less numbers in the upper alimentary tract. The ovary was frequently infected, but spirilla were not found in deposited ova. 7. With the increase of the epidemic among the girls, body lice became more in evidence. 8. With the subsidence of the epidemic amongst the boys the percentage of infected lice fell. 9. An attempt to infect a monkey by means of lice failed. These facts are sufficient to throw grave suspicion on the body louse as a transmitter of relapsing fever. Many epidemiological facts point to this mode of transmission as being a likely one, and the life history and habits of body lice show that these parasites well fulfill the necessary conditions for spreading the disease. Thus relapsing fever has always been associated with poverty stricken, overcrowded, and half starved communities, and it is just under such conditions that lousiness is at its worst. Again, in mixed communities the disease attacks the poor and dirty living in squalid tenements, to the exclusion of those of cleanly habits and better conditions of life. Relapsing fever is a "personal" and not a "place" disease, and among stricken communities the infection spreads from person to person very rapidly after only a few days' exposure, and mere contiguity without contact is not sufficient to carry on the infection. It is probable that the infected secretion of the louse's mouth is the medium responsible for transmission during the height of an epidemic, but whether the ovarian infection plays any part in the linking together of epidemics or in the carrying over of the disease during the off season it is impossible to say, but the failure to find spirilla in nits is against this theory.

**5. Return Cases of Scarlet Fever.**—Habgood states that of recent years it has been recognized that where return cases of scarlet fever occur the discharged patient will be found to have some purulent or mucopurulent discharge. While admitting the impossibility of being sure that all inflammation has ceased in the upper respiratory tract, he is inclined to believe that cases are occasionally sent out free from any nasal discharge and not infectious, but do again become infectious by the occurrence of an ordinary attack of nasal catarrh, which causes some remaining scarlet fever germs to renew their activity.

By H. J. ROBSON.

1. **Genitourinary Tuberculosis.**—Godlee in the Bradshaw lecture discusses prognosis in relation to treatment of tuberculosis of the genitourinary organs. As regards the most frequent form, tuberculosis of the testicles, he has come to the following conclusions: 1. That it is usually a chronic disease and that a majority of those cases which appear to be acute or subacute have been preceded by a slow enlargement of the organ which has escaped the attention of the patient. And this is based upon the facts that thickenings of the epididymis are often discovered accidentally, and that in operations on the acute or subacute cases more extensive cheesy masses are usually met with than it is possible to suppose could have been formed since the apparent onset of the disease. No doubt the acute process does occur, but it is exceptional. 2. That it is so common as to be almost the rule for the second testicle ultimately to be affected, whether the first has been removed or not. The writer has given up removing every tuberculous testicle, however quiescent, if no sign of the presence of tubercle could be found elsewhere, because it so often leads to disappointment, the patient returning with the other testicle affected. For the same reason he deprecates extensive operations upon the vas deferens and vesicular seminales. He does not hesitate, however, to remove one testicle which is completely disorganized, both body and epididymis, if it is causing much pain or inconvenience, and under such circumstances takes away as much of the vas as can easily be got at. Thorough curetting of the epididymis often gives excellent results. If after orchidectomy the other testicle is subsequently affected it should not be removed, but the obviously diseased portions should be cut away or scraped. The internal secretion of quite a small portion of the organ is sufficient to ward off the unpleasant results of complete castration. A very considerable deposit of tubercle may occur in the prostate without causing any symptoms whatever, and the process go on to almost complete atrophy of the gland. Sometimes an abscess forms, causing retention of urine, and, if it does not burst in the bladder, necessitating a perineal opening.

## 2. Gastric Conditions in Wasted Infants.

Miller and Willcox suggest that in dealing with wasted infants we take advantage of the modern methods of analysis of the gastric contents. As a result of their investigations they find that differences exist in the gastric secretion in infantile wasting, corresponding to three clinical groups, as follows: 1. Pure marasmus or atrophic dyspepsia. As a result of prematurity, immaturity, insufficient or improper feeding, etc., the infant wastes. There is a furred tongue, with a tendency to diarrhoea and vomiting, and progressive wasting, with no signs of any acute local disease. Post mortem no changes are found other than atrophy. Examination of the gastric contents shows a diminished activity of both acid and ferment secreting glands, no retention of food in the stomach, and no mucin. 2. Hypertrophic pyloric stenosis. Most usually in a male child vomiting starts in the first few weeks of life; the vomitus quickly becomes large in amount, forcible in character, and is accompanied by rapid wasting. Constipation is usually marked, the stools being small and marblelike. The tongue is generally very furred. The physical signs are definite gastric peristalsis and a palpable pyloric tumor. The contents of the stomach show, as a rule, a marked increase in the ferment activity, together with excessive secretion of mucin. There is also very obvious retention of food in the stomach. The total acidity varies, but tends to be below normal. After regular gastric lavage has been carried out for a short period, the gastric contents lose their abnormalities. 3. Acid dyspepsia. Here the symptoms tend to occur in children three months of age or over. The vomiting is large in amount and may be rather projectile in character, and the bowels are constipated. The wasting is considerable, but less than in pyloric stenosis. The tongue is clean, and the abdomen is usually full. No true peristaltic waves are seen, nor is the pylorus palpable. The gastric contents show an increase in their total acidity, the ferment activity being normal, or below normal. There is no mucin present, but there is obvious retention of food in the stomach. In atrophic dyspepsia pepsin and acids should be given. In acid dyspepsia alkaline gastric lavage, together with the administration of alkalies, such as bicarbonate or citrate of soda, are indicated. In pyloric stenosis the best diet is one of a noncoagulable nature, such as a whey and cream mixture. The smallest practicable doses of food should be given, so as to avoid setting up a fatal diarrhoea in the atrophied intestine.

## 8. The Eyelid and Lower Jaw Phenomenon.

—Robson discusses the following phenomenon, which is apparently never present in health: Upon protrusion of the tongue or depression of the lower jaw, there is a slight eversion of the lower eyelids, the lids resuming their normal state when the tongue is retracted or the mouth shut. The writer regards it as a new sign of disease with some diagnostic significance. Among his general conclusions are the following: 1. The phenomenon cannot be detected unless it is specially looked for, because, as a rule, the tongue and eyes are not inspected at the same time. 2. Whenever it is present in chronic cases some severe asthmatic condition will always be found.

to exist, or it will be found that the patient has been a martyr to pain for many years. 3. The phenomenon for a time almost disappears after the tongue has been protruded several times and also after stroking the forehead or touching the lower eyelid. 4. In all cases observed but one it was present in both eyes. 5. In three cases the phenomenon disappeared as the patients convalesced from their various maladies. 6. In two cases it has gradually disappeared coincidentally with a marked improvement in the general health of the patients. 7. In two acute cases it disappeared when the urgent symptoms passed off. 8. In most of the chronic cases the patients are affected with various cardiac and abdominal diseases. 9. The phenomenon is never present in health. It comes and goes with the onset and cure of disease, and is a clear index or sign of disease.

By C. FOIX and E. MALLEIN.
2. Faradization in Syncope from Chloroform,  
By JEAN M. VILLETTE.
3. Mercurial Pills,  
By ALEXANDER RENAULT.
4. Atoxyl and the Sleeping Sickness,  
By R. ROMME.

1. The Reaction of Bordet and Gengou in Respect to the Streptococcus in Scarlet Fever.—Foix and Mallein state that without entering into a discussion as to the streptococcic nature of scarlet fever they can give the following as established facts; 1. The serum of persons with scarlet fever contains antibodies to the streptococcus, antibodies which they have found ten times out of twelve by means of the reaction of Bordet and Gengou. 2. They have found this to be the case as early as the fourth day, and as late as the thirty-eighth day. 3. The reaction of Bordet fails in regard to the streptococcus in the other streptococcic conditions. 4. It remains to be established whether this is a specific reaction to the streptococcus of scarlet fever, or a reaction common to all or to many species of streptococci. 5. This reaction may be utilized as serodagnostic.

2. Faradization in Syncope from Chloroform.—Villette reports some of his experiments on dogs and alleges that the use of faradization in syncope from chloroform is of advantage in three ways: It produces a large and complete respiratory effect, the procedure is of a true physiological nature, and it furnishes the adjuvant action of sensory stimulation.

By E. JOHNSON.
3. Clinical Examination of the Outward Form of the Neck,  
By P. DESFOSSÉS.
4. Treatment of Delirium Tremens,  
By LEGRAIN.

1. Appendicitis.—Baumgartner reviews the questions which have arisen, as indicated by the title of his paper, and gives these conclusions: 1. Medical treatment may be permitted in the first attack of acute appendicitis, when no disquieting

symptoms are present, or when, after twelve, or at the most twenty-four hours, there is a manifest improvement which continues. 2. When any serious symptoms appear, or when improvement is not manifest after twenty-four hours of temporization, an operation should be performed immediately. 3. The operation should always consist of the ablation of the appendix, except in cases in which serious difficulties present a contraindication. 4. Every person who has had a clear attack of appendicitis should have the appendix removed, even though all morbid symptoms have disappeared.

2. Changes in the Terminal Phalanges in Cyanosis.—Jourdan describes with the aid of radiographs the alterations which took place in the terminal phalanges of a woman, twenty-two years of age, who suffered from chronic cyanosis due to valvular lesion of the heart. The changes in the bony tissue he ascribes to the lessened nutrition dependent on the trouble in the capillary circulation.

14. Impressions of America,  
By MÜLLER.

1. Dangers and Treatment of Placenta Prævia.—Zweifel thus summarizes the principal indications for treatment. Every severe hæmorrhage in the second half of pregnancy which suggests the thought of placenta prævia should be so treated, because of the very great danger that a second hæmorrhage may cost the life of the mother. To do this the woman should be tamponed for some time, at least a week, unless the birth takes place in a less time. For a long continued tamponade nothing can take the place of the colpeurynter. All material used for the tamponade must be aseptic. The best method to induce labor is the artificial rupture of the amnion, but this can be per-

formed only in cases in which the membrane bulges forward, and this is rarely the case in placenta prævia. As a rule the hæmorrhage is checked most certainly, and with the best maintenance of asepis by version performed as soon as possible, by the combined method of Braxton Hicks when the cervix is faultily dilated. Extraction should not follow until the cervix is nearly or quite dilated on account of the danger of lacerations of the cervix. At the same time this delay adds to the danger of the child and should not be persisted in to its detriment. Where a laceration is not to be feared active procedures should be taken, and as the laceration takes place only when the head is being drawn through it is possible while waiting in this stage of labor to prevent a laceration and yet to protect the child from suffocation by holding his fingers so that the child can draw air into its lungs by respiration, or by introducing a catheter into its mouth. In central placenta prævia one should first try to displace the flap of the placenta with the two fingers with which he performs the combined version, because this procedure is less injurious to the child than boring through the placenta. When this cannot be done the placenta can be perforated at any time, and as hardly a child survives there is no object then in hastening the delivery. Very often in placenta prævia the question is that of miscarriage, and then no active treatment should be undertaken, because this offers little hope of the life of the child and is more dangerous to the mother. The author deprecates the performance of either abdominal or vaginal Cæsarean section in these cases.

2. **Appendicitis in Children.**—Riedel states from a study of the cases met with in the clinic at Jena during the past twenty-one months that the mortality among children under fifteen years from appendicitis was 13 per cent., while that among adults was 2.9 per cent. The reasons he gives in explanation of this enormously greater mortality among children are the carelessness of parents and their dread to submit their loved children to an operation; the fact that it is more difficult to diagnose appendicitis in children than in adults; that from anatomical causes appendicitis is more dangerous in children than in adults, and that very little children are extraordinarily susceptible to infection from the appendix.

3. **Treatment of Pulmonary Phthisis and Alveolar Emphysema by Operative Mobilization of the Thorax.** Freund calls attention to the fact that he was the pioneer in this operation, that he performed it as long ago as 1858 or 1859, and asserts that if performed by competent surgeons it is not dangerous, and is able to relieve the conditions of tuberculosis of the apex of the lung and of alveolar emphysema.

4. **The Surgical Treatment of Certain Cases of Pulmonary Emphysema.** Stricker reports a case of emphysema in which he successfully performed Freund's operation and concludes that the operation is sure to be of benefit in certain cases of chronic pulmonary emphysema which are dependent on a primary rigidity of the thorax caused by degeneration of the costal cartilage.

5. **Acute Poisoning with Benzol Vapor.**—Lewin says that a man may be acutely poisoned by the inhalation of benzol vapor and recover; that long persistent sequelæ may afflict a man after a slight acute benzol poisoning; that chronic disease may be induced by repeated poisoning by benzol; that men who inhale a large quantity of concentrated benzol vapor may die in from a few minutes to an hour.

6. **Zinc Chloride in the Treatment of Endometritis.**—Hofmeier reports a case in which death from peritonitis followed the injection of a solution of zinc chloride into the uterus.

9. **Bolus Treatment of Diarrhœa.**—Görner has obtained favorable results with the administration of finely pulverized white clay and considers it particularly indicated in acute gastrointestinal catarrh.

10. **Treatment of Epididymitis and of Buboes with Hyperæmia.**—Stern speaks very highly of the results he has obtained by the use of hyperæmia in these conditions, and states that he has never seen any bad after effects. He produced the hyperæmia by means of large suction glass.

12. **Pubiotomy.**—Haun suggests that a pubio-pelvioplastic operation might be performed on young women with narrow pelves at the time of their first labor which would correct their condition once for all and render unnecessary a repetition of a pubiotomy with each succeeding pregnancy.

13. **Sterilization Apparatus for Laboratory Work.**—Prausnitz describes a sterilizer which he has used for twenty years in laboratory work. The sterilization is accomplished by means of steam.

7. An Analysis of 832 Cases of Scarlet Fever, with Observations on the Diagnosis and Treatment of the Disease, By W. N. BARLOW.
8. On the Necessity of Caution in Diagnosing Hysteria, By B. MYERS.

1. **Remarks on Appendix Abscess.**—Battle says that a waiting policy is not advisable in this condition, for a favorable termination can seldom be prognosticated with assurance. Many dangers may be avoided by the early evacuation of such an abscess, for (1) it may open into the bladder, large bowel, or rectum; (2) it may extend to the pelvis and left side of the abdomen, or into the hepatic region or even into the pleural cavity; (3) it may rupture into the peritoneal cavity; (4) it may cause general toxæmia; (5) it may be complicated by intestinal obstruction. Stress is laid upon the importance of rectal examination, especially in cases in which the symptoms are mistaken and the disease

signs few. It is thought that removal of the appendix is not indicated as a routine practice. The opening of the abscess is without danger if done by a competent person, but the search for the appendix in the wall of an abscess may cause serious trouble. The mortality of appendix abscess from all causes in a consecutive series is placed at 10 per cent., but if treated surgically from the first it should be under 5 per cent.

2. **Movable Kidney.**—Howell and Wilson find that in many cases of movable kidney no symptoms are present. In cases with pain this symptom varies within wide limits. The cases may be acute or chronic, and the former may be traumatic or acquired. In the acute cases the symptoms are referable to the mechanical obstruction of the renal vessels or the ureter, or of both at the same time. Resemblance to renal calculus is suggested by the paroxysmal character of the pain, by its frequent recurrence, by being made worse by exertion and relieved by rest, and by the presence of blood and albumen in the urine. An x ray examination will often assist in clearing up the diagnosis. Hydro-nephrosis is a possible result when there is rotation of the kidney. If the renal vessels are obstructed no tumor will be found in the loin, but the urine will contain blood, casts, and albumin. In the chronic cases pain which varies in severity is the most common symptom. Neurasthenia is often associated with movable kidney. Treatment in the majority of cases by the pressure of a well fitting truss will be satisfactory. In only a comparatively small percentage of cases is nephrorrhaphy indicated.

4. **Malignant Disease of the Testis.**—Howard states that the diseased testis should be removed as soon as the diagnosis is made, even though there is evidence of secondary enlargement of lumbar glands. No case in which the disease is thus advanced can be cured by operation, but death from subsequent recurrence in internal organs is thought preferable to the undisturbed progress of the primary disease. In only three of the author's recorded cases did recurrence take place in the scar of the wound. Operation is contraindicated if the lumbar growth is a large one, or if other organs are already infected. If the cord is infiltrated, removal of the organ will also be futile, as the growth will fungate through the wound, and the hæmorrhage at the time of operation may be very difficult to control.

5. **Suppuration in the Region of the Pharynx.**—Fitzwilliams recalls the fact that this subject has attracted the attention of many eminent writers. He analyzes a series of seventy-five cases observed among children, and divides them into the following groups: 1. Quinsy or suppuration in and around the tonsil, the pus being always superficial to the pharyngeal aponeurosis. 2. Retropharyngeal abscess, in which the suppuration starts in the retropharyngeal space. The abscess is outside the pharyngeal walls, between the buccopharyngeal aponeurosis and the prevertebral layer of the deep cervical fascia. 3. Postadenoid suppuration, which is between the lymphoid tissue in the mucous membrane and the pharyngeal aponeurosis. 4. Suppuration or caseation in the deep cervical glands,

and extending inward to the lateral pharyngeal wall. 5. Cold abscess due to spinal caries and lying behind the prevertebral layer of the deep cervical fascia. Opening of these abscesses by incision from the inside is desirable in the majority of cases. A general anæsthetic, to a moderate extent, should be employed, except in very young infants and in cases in which dyspnoea is urgent.

6. **Ascites Associated with Hepatic Cirrhosis.**—Ketchen and Thomson call attention to the fact that ascites due to hepatic cirrhosis is now better treated by surgical operation than repeated tapings. It is desirable, however, to first learn the cause of the ascites in a given case before submitting it to operation. Two classes of cases are recognized in connection with cirrhosis of the liver. In the first free fluid in the abdominal cavity shows itself when there are few symptoms of general systemic poisoning. Such cases are benefited by tapping. In the second class the ascites occurs in the late stages of the disease, when there is general systemic disturbance. The fluid in both varieties is due to peritonitis. In the first variety the peritonitis is not dependent on changes in the liver, but the same cause which produces the slow inflammatory changes in that organ also produces the peritonitis. Drainage is effective in such cases, and the disease may remain stationary for years. In the second variety the peritonitis is toxæmic; the poisons find their way into various organs, and removal of the fluid is in no way beneficial. If the patient's general condition is good, and the heart and kidneys in fair condition, an omentopexy will usually prove beneficial.

## Proceedings of Societies.

### MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

*Meeting of December 16, 1907.*

The Vice President, Dr. R. E. VAN GIESEN, in the Chair.

**Memorial of Dr. Seth D. Close.**—The report of the committee on the death of Dr. Seth D. Close, of the borough of the Bronx, who died on October 20, 1907, was presented by the chairman, Dr. N. B. Van Eetten.

**Bile Changes in Infective Diseases.**—This paper, by Dr. H. BALDWIN, gave the results of an investigation of 225 autopsies made in various New York hospitals in the years 1903 and 1904. The study was conducted in Professor Herter's laboratory, under a grant from the Rockefeller Institute for Medical Research, and was undertaken primarily for the determination of cholesterol. In no fewer than seventy-two instances there were found marked definite changes from the normal condition, and yet during life the symptoms had been so mild that cholecystitis had been diagnosed in only two of the cases. The various abnormal changes detected in the constitution of the bile and the presence of abnormal elements were described. In a considerable number of instances infectious bacteria were found, in seven instances leucocytes, and in two blood. The results obtained indicated that in the infectious disease the frequency of bili-

ary involvement and the danger of the formation of gallstones was not sufficiently recognized.

**Blood Reactions of Inflammation.**—In this paper the author, Dr. E. E. SMITH, spoke first of the absolute number of leucocytes, stating that it was an established fact that often during the active period of inflammation there was an increase in the absolute number of leucocytes in the circulating blood. This increase was known to be a reaction resulting from the production at the site of the process of positive chemotactic substances, which substances might be derived either from the tissue cells or from infecting bacterial organisms. As an illustration of such substances originating from the first source he mentioned the exudative stage of inflammation in an active appendicitis, where it was fair to believe that the chemical substances calling forth the leucocytes were almost wholly the product of the defending tissue cells. If, however, the tissue cells had been so lacking in vitality as to be incapable of defense, the bacterial invasion would have predominated and a degree of injury to the tissue cells resulted, such as would produce death of tissue, instead of calling forth the process of defense. The same result might follow an unusually virulent bacterial invasion, even though the initial vigor of the tissue cells was not impaired. Under such conditions the calling forth of an absolute leucocytosis was less marked than in an active inflammation. Clinically, there was in an active process a high leucocyte count in proportion to the degree of activity; in the less active gangrene the leucocytes were increased to a lesser degree. In considering the increased leucocytosis it must be borne in mind that generally there was an accompanying increase of leucocyte formation by the blood producing organs. The view, thus put forth, that leucocytosis was proportional to the active production of chemotactic substances by the tissue cells, and that it was not produced altogether or in most instances largely by the bacteria, the speaker said, explained some supposed failures of the absolute leucocyte count in diagnosis. It was occasionally noted that pus failed of recognition by this means. In such cases it would always be found that the pus was more or less of the stagnant variety, and the failure of leucocytosis was not due directly to the walling in of pus, but to the absence of active defense, which the walled off product no longer aroused.

In the leucocytosis of inflammation there was not only an increase in the absolute number of leucocytes in the blood, but also, usually, a relative increase in the proportion of those of the polymorphonuclear variety. The existence of this relative increase might be regarded as of even greater diagnostic import than the absolute leucocytosis, particularly as its entire absence was much less frequent in cases presenting conditions which would be expected to call forth a blood reaction. It seemed to the speaker that the possible explanation of the relative leucocytosis, without a corresponding absolute increase, was to be found in two factors: 1. A diminished rate of formation of the chemotactic substances. 2. A less active leucocyte formation. Whatever the cause, the relative polymorphonuclear increase was a certain indica-

tion that there was a factor operative in bringing forth the leucocytes which was not physiological. Moreover, the greater the relative increase the more urgent was the call of the diseased tissue; while, again, the less response by an absolute increase the less was the injured tissue able to declare its needs.

The conclusion of the paper was devoted to a third change which the blood might undergo in inflammation, namely, an increase in the amount of fibrin formed when the blood was removed from the body. This character, Dr. Smith said, was so marked in certain cases, its detection was so simple, and its indications were so definite, that it was surprising that it was not more frequently considered. Fibrin formation was due to the action of fibrin ferment on the fibrinogen of the blood. The fibrin ferment in turn was formed from its inactive precursor, prothrombin or thrombogen, by the action of thrombokinase, which was liberated from the leucocytes. The throwing into the circulation of thrombokinase not only tended to produce fibrin in increased quantity at the site of the inflammatory process, but gave to the systemic blood in general the property of forming fibrin in increased amount. This fact afforded a most valuable diagnostic feature of the blood, being an index to the extent and degree of the formation of fibrinous exudate in the body. This being the case, we should expect to find no increase of fibrin in slight localized inflammation or in suppuration, and a great fibrin increase in inflammatory processes in which there was much formation of fibrinous exudate. The value of this observation was not only to determine the character of the process in a given case, but also to diagnosticate changes occurring at different stages of the disease.

**Bacterial Vaccines and Curative Sera.**—The author of this paper was Dr. C. F. BOLDMAN, bacteriologist of the Research Laboratory of the New York City Health Department. Having referred to the generally acknowledged success of diphtheria antitoxine, he said it was obvious that such toxine as had already combined with the cells could not be neutralized by the antitoxine. Hence, in desperate cases, seen late, the antitoxine should be given in a massive dose intravenously, under aseptic precautions; and in this way lives might sometimes be saved which otherwise would have been sacrificed. As was well known, tetanus antitoxine had not proved nearly so successful, and this was mainly due to two causes: 1. In tetanus the diagnosis was not made until the onset of tetanic symptoms, where the specific toxine had entered into so firm a combination with the susceptible cells that no amount of antitoxine would prevent the toxic action. 2. The strong affinity which the toxine had for the vitally important cells of the central nervous system. There was, however, a distinct field for tetanus antitoxine, in which its use was of unquestioned value. This was in a prophylactic in cases in which tetanus infection seemed probable, and here its employment should become more general than was at present the case.

Considerable work had been done with specific antisera in cholera, typhoid fever, and other diseases. These sera were bactericidal, killing and

dissolving the bacteria against which they were specifically directed; but clinical trials soon showed that they had little therapeutic value, while laboratory experiments subsequently disclosed many difficulties in their practical application. Such sera had, however, been used with some success in immunizing against infection, especially when employed in what was known as the combined method. In the past few years it had become more and more apparent that the limitations of serum therapy were, for the present at least, practically insurmountable, and therefore attention had again been turned to treatment by active immunization. The scientific foundation for this was laid by Pasteur, but, believing that the production of immunity required the action of the living virus, Pasteur vigorously combated the idea that immunity could be brought about by means of dead virus or of lifeless products of growth of the viruses. To Salmon and Smith, of this country, belonged the credit of first clearly demonstrating the possibility of immunization with dead cultures. Active immunization could, then, be carried out in several different ways: 1. By means of living cultures (usually attenuated) of the virus. 2. By means of dead cultures of the virus. 3. By the so-called combined method—by first administering a dose of the specific immune serum and subsequently the virus. This method had been used in typhoid fever, cholera, and plague. 4. By means of the products of autolysis of the cultures. 5. By means of various combinations of these methods.

At first, active immunization was applied only to prophylactic treatment, and the first attempt to use this method in curing an infection already in progress was Koch's tuberculin treatment of tuberculosis. Having presented some explanation as to how active immunization could accomplish anything in the curative treatment of an existing infection, Dr. Bolduan went on to say that this kind of treatment of infections had been greatly stimulated by the work of Wright, who had reported favorable results in a large number of infections. Richardson, in a recent publication on the treatment of typhoid fever, stated that by using certain bacterial vaccines prepared after the method of Vaughan he had found that the typhoid process was apparently made longer, but milder, and that by continuing the treatment into convalescence the liability to relapse was diminished. In the use of bacterial vaccines there should constantly be kept in mind the nature of the bacterium employed and the kind of immunity desired to be brought about. Everything depended on the way in which the vaccine was prepared. Having given Koch's method of preparing tuberculin, the author said it was probable that the technique recently introduced by Pirquet and by Calmette would lead to the more extensive employment of tuberculin in the diagnosis of tuberculosis in the human subject. He then described Wright's method of preparing a bacterial vaccine (for example, a staphylococcus, typhoid, or streptococcus vaccine), and stated that the doses to be administered varied with different bacteria, and also according to the indications, opsonic or clinical. The ordinary dose for the staphylococcus vaccine was from 200 to 1,000 million organisms;

for the streptococcus, from 50 to 100 million; and for typhoid, from 750 to 1,000 million. All the injections were given subcutaneously, and it was usually advisable to repeat the injections every three or four days.

With regard to the value of the opsonic index, which he defined as the relative phagocytic power of the patient's serum compared with the average of several normal sera, he said that these determinations were very difficult to make and were subject to a number of unavoidable errors. His own experiments had shown that the results of duplicate or more determinations of the same serum, at the same time and under apparently identical conditions, often yielded widely divergent results, while frequently also there was a considerable variation in the opsonic indices of several normal persons. Finally, the opsonic index and the clinical course of the disease did not always run parallel. It would certainly be surprising, therefore, if the opsonic power were to prove the real measure of the degree of immunity, and at the present time he believed it would be inadvisable to control active immunization with bacterial vaccines solely by measurements of the opsonic index. Clinical observations must still occupy a prominent place in determining results.

#### **Poliomyelitis Anterior as an Epidemic Disease.**

—Dr. HENRY W. BERG, who read this paper, said that during the recent epidemic he had seen some twenty-five cases, most of them in consultation. The disease was not limited to any class of society, and was often found in children living under the best hygienic surroundings. While some of the cases were of the character classically recognized as infantile spinal paralysis, or anterior poliomyelitis, in many the affection presented itself clinically as a combination of the symptoms characteristic of anterior poliomyelitis with those of acute bulbar paralysis, so that it might well be termed a poliomyelencephalitis. The patients in whom there was a febrile temperature of long duration suffered from a paralysis of lesser extent than those in which the duration of the fever was short. From his experience in this outbreak Dr. Berg had become impressed with the idea that epidemic poliomyelitis was a radically different disease from sporadic poliomyelitis anterior; differing, indeed, in aetiology, pathology, clinical history, prognosis, and treatment, and it seemed to him that if this distinction could be maintained, much that was confusing and contradictory in recent clinical and pathological studies of anterior poliomyelitis, as compared with the older and equally comprehensive studies, would be explained. The recent pathological observations were almost exclusively studies of patients dying in epidemics of the disease, while the older classical conceptions were based upon autopsy findings in sporadic cases. In sporadic cases the permanency of the paralysis was a distinctive feature, while in the epidemic form of the disease the paralysis not infrequently disappeared within two months or less. This and other points would seem to emphasize the importance of the clinical study of epidemic cases as contradistinguished from the sporadic; and particularly in view of the fact that the recent epidemic in New York and its vicinity was the largest yet recorded of this disease.

It was an interesting fact that epidemics of this disease appeared to occur in the hot months of the year, and particularly in seasons when the rainfall was abnormally small. From reports by the United States Weather Bureau he had found that in New York the total precipitation during July, 1907, was only 1.18 inch, of which .55 inch occurred on a single day of the month; while the average precipitation for July for thirty-seven years past was 4.38 inches. During August, 1907, the total precipitation was 2.48 inches, against an average for August for thirty-seven years of 4.53 inches. In MacPhail's report of the large epidemic in Vermont he noted that the season had been exceptionally dry. The question of the contagiousness, or rather the communicability, of the disease had been studied in some epidemics, particularly those occurring in Norway and Sweden, and Dr. Geiersvold, who reported his investigations to the Swedish government, had expressed his conviction that the disease was contagious. Horbitz and Scheel agreed in this view, although they acknowledged that in the city of Christiania a painstaking investigation failed to demonstrate any connection between the cases. In his own experience during the past summer Dr. Berg did not see more than one case in any one family. Most of his cases were seen in the family practice of other physicians, and these patients, like the great majority of those met with in the city, were in close contact with other children. That, under these circumstances, no cases pointing to direct contagion should have occurred, was strong, if negative, evidence that this epidemic disease was not contagious. One peculiarity of the epidemic form of the disease, distinguishing it from the sporadic, was the fact that it occurred in older children as well as infants, while even young adults had sometimes been attacked. Of the nineteen autopsies in recent epidemic cases in Norway studied by Horbitz and Scheel, eight were on adults.

The symptomatology of the epidemic type of the disease was very different in many respects from that of the acute stage in sporadic cases. Thus, the fever was of longer duration and was a more prominent and constant feature. There was hyperaesthesia of the entire surface of the body, and in many cases seen on the first, second, or third day there was some rigidity of the neck and spine. The patellar reflexes were absent in most of the cases, and the initial rigidity of the back of the neck usually soon gave way to flaccidity of the muscles in this situation. In some of the older children (from three to eight years of age) there were incontinences of faeces and urine; symptoms not met with in sporadic cases of the disease. Three of Dr. Berg's patients had acute bulbar paralysis, and died of symptoms due to the involvement of the hypoglossal, glossopharyngeal, and pneumogastric nuclei. Fortunately, there are now at our command the records of many autopsies in cases of death from epidemic (so called) poliomyelitis anterior during the acute stage, with careful macroscopical and microscopic findings in the spinal cord, brain, and other organs. Although such autopsies were extremely rare, we also had at least four carefully recorded autopsies in sporadic cases of the disease

terminating during the acute stage. Comparing these cases with some of those of death in the acute stage of the epidemic disease, it would be found that, while in the sporadic cases the lesions were limited to special parts of the spinal cord, in the epidemic cases there was a general inflammatory process extending throughout the brain and spinal cord, as well as the pia mater of both the brain and cord. No microorganism had as yet been found for the epidemic disease. The cerebrospinal fluid obtained by lumbar puncture had always proved sterile, cultures made from it were negative, and animals injected with the fluid suffered no pathological change. From his study of the affection Dr. Berg thought that it should properly be termed epidemic meningomyeloencephalitis. In conclusion, he reiterated his conviction that sporadic poliomyelitis anterior was entirely distinct from this. The sporadic disease was not infectious, while the epidemic disease was in all probability infectious, but not contagious.

Dr. HARLOW BROOKS said that, while he desired to congratulate Dr. Smith on the best presentation of the subject which he had ever heard, he could not but disagree with the author in the roseate view which he had taken of the importance of leucocytosis. After all, this was nothing but a symptom. In a great many instances we did not observe it where we had a right to expect it, and often the reverse of this was true. The same was true, he had found, in regard to the polymorphonuclear increase also. He must differ, too, in regard to the fibrin reaction. He had tried this again and again, with very uncertain results. It did not seem to be the simple matter that Dr. Smith would have us believe, and no two men could be found to agree as to the fibrin formation. Sometimes, indeed, it was present, but, in his opinion, more often it was not.

Dr. N. B. POTTER said that experience seemed to show that affections in which there was a localized infection, as in anthrax, were often decidedly improved by bacterial inoculation, while the general diseases were not as a rule so favorably affected. He referred to six cases of streptococcal infection reported by Myers in which streptococci were recovered from the blood, and said that three of the patients had recovered, while the other three had died. In two cases of Dr. Bristow's, of Brooklyn, he had personally employed streptococcus vaccine, and both patients had recovered. The same was true of two cases of puerperal infection in the practice of Dr. Charles Jewett, and he had had similar results in other instances also.

Dr. E. S. SMITH, speaking on Dr. Berg's paper, said that, while the recent epidemic had been discussed very fully in many societies, he thought it would have been very desirable if the discussion of the whole subject could have been postponed until a year from now. We were now learning about the disease, and, with the completion of the systematic investigation which was in progress, we should then know a good deal more about it than we did at present. He could not agree with Dr. Berg that the epidemic form of the affection was essentially different from the sporadic, any more than epidemic cerebrospinal meningitis differed from the sporadic. The

only distinction was that when anterior poliomyelitis occurred sporadically we had very little opportunity of studying the early manifestations of the disease. This epidemic had shown us that the disease as now seen was not at all the affection described by Charcot. We must accustom ourselves to the fact that we had to do with a distinctly infectious disease. In one of the cases which he had seen all the clinical features of a multiple neuritis were present, and yet he believed that it was entirely identical with other instances of poliomyelitis. This patient had been taken ill in August, and was still in the hospital. In another case, that of a boy, there was hemiplegia and also facial paralysis. As to the relation of a diminished rainfall to epidemics of anterior poliomyelitis, this would seem to be a matter of importance if such relationship could be established. Learning of Dr. Berg's studies in this direction, Dr. Strauss had obtained through the government at Washington some meteorological statistics from Sweden, and from these it would appear that the rainfall in the seasons when epidemics had occurred in that country did not differ materially from the average. Great care should be taken to avoid false inferences in such matters.

Dr. W. M. LEEZYNSKY said that sporadic cases did not correspond to those seen in an epidemic. Were it not that an epidemic was present, a large number of the cases met with would not be classed as anterior poliomyelitis at all. He described two illustrative cases presenting peculiar types, and concluded by expressing the hope that when the present investigation had been completed the name assigned to this epidemic disease would be something else than anterior poliomyelitis.

Dr. N. B. VAN ELTEN stated that in his practice he had met with three cases in one family, the children being taken ill about three days apart.

Dr. BERG said that in his paper he had expressly contended that the disease of the recent epidemic was not poliomyelitis. This, he believed, was fully established by the series of autopsies he had described. In the four recent autopsies in sporadic cases which were given the conditions found were entirely different from those met with in the epidemic cases.

### Book Notices.

*A Textbook of Clinical Anatomy.* For Students and Practitioners. By DANIEL EISENDRATH, A. B., M. D., Adjunct Professor of Surgery in the Medical Department of the University of Illinois, etc. Second Edition. Thoroughly Revised. Philadelphia and London: W. B. Saunders Company, 1907. Pp. 535. (Price, \$5.)

Professor Eisendrath, in publishing his book, has filled a much felt want. The students are taught anatomy together with physiology and pathology as fundamental subjects of medicine, during the first two years of their course of education. Topographical anatomy is the bridge connecting these studies with the later ones, given in the clinics and clinical lectures. While anatomy is taught by post mortem dissection we very often see an entirely different picture *in vivo* on the operation table or the sick bed. A textbook of clinical anatomy, therefore, will be highly appreciated by both students and

practitioners. The present volume is the second edition, and is divided into chapters according to the anatomical region of the body, every chapter being introduced by an explanation of examination during life. The index is also of great help. The text is condensed without disadvantage to clearness, and gives a good description of the material. It is accompanied by well adapted and advantageously selected illustrations, which are clearly and distinctly executed. But why use the fig leaf? This device of prudish censorship may be called for—though we doubt it—in public places and museums, but it is out of place in books of art and absolutely absurd, not to say ridiculous, in medical works. Eisendrath's otherwise good book would gain immensely if these devices—which, by the way, are not even strictly carried through—were to disappear from future editions.

*Principles and Practice of Modern Otology.* By JOHN F. BARNHILL, M.D., Professor of Otology, Laryngology, and Rhinology, Indiana University School of Medicine, etc., and ERNEST DE WOLFE WALES, B.S., M.D., Associate Professor of Otology, Rhinology, and Laryngology, Indiana University School of Medicine, etc. With 305 Original Illustrations, Many in Colors. Philadelphia and London: W. B. Saunders Company, 1907. Pp. 575. (Price, \$5.50.)

A volume entitled *Modern Otology*, dedicated to all English speaking students and practitioners of medicine, and having in view, as the authors state, among other things, the modernization of the subject and the correction of certain strangely persistent beliefs in regard to aural ailments, attracts attention and challenges criticism. The authors have no reason to be dissatisfied with the results of careful perusal by an impartial reviewer. They have given a well written and particularly well illustrated presentation of the diagnosis and treatment of diseases of the ear, and, what is more, have laid more than usual stress on the subject of prophylaxis. Thus, the influence of nasal and nasopharyngeal disease, heat and cold, and of constitutional disorders are fully discussed in their practical bearing on otology. The operative and diagnostic technique is clearly described, and the cuts illustrative of the various procedures are excellent. The intracranial complications of otitic disease are discussed in the light of most recent clinical and pathological studies. The bacteriology of aural discharges, the surgery of the facial nerve, the relation of otitic suppurative to life insurance, labyrinthine syphilis, lumbar puncture, and the causation of ear diseases, are titles of chapters or subdivisions indicating the wide scope and completeness of the work.

*Pharmacology and Therapeutics.* By REYNOLD WEBB WILCOX, M.A., M.D., LL.D., Professor of Medicine at the New York Postgraduate Medical School and Hospital, etc. Seventh Edition, Revised, with Index of Symptoms and Diseases. Philadelphia: P. Blakiston's Son & Co., 1907. Pp. ix-885. (Price, \$3.)

In the seventh edition of this book a good deal of condensation has taken place as compared with the sixth edition, which appeared two years ago. It is a welcome reference book, and every physician will appreciate its value. *Materia Medica and Pharmacy*, by the same author, should be taken as its second volume.

## Public Health and Marine Hospital Service Reports:

*List of Changes of Stations and Duties of Commissioned and Noncommissioned Officers of the United States Public Health and Marine Hospital Service for the seven days ending December 28, 1907:*

- BAILEY, C. W., Acting Assistant Surgeon. Granted leave of absence for seven days from November 21, 1907, on account of sickness.
- CLEAVES, F. H., Acting Assistant Surgeon. Granted leave of absence for five days from September 23, 1907, under paragraph 210, Service Regulations.
- EARLE, B. H., Passed Assistant Surgeon. Granted leave of absence for ten days from December 24, 1907.
- GAHN, H., Pharmacist. Granted leave of absence for eight days from December 21, 1907.
- LLOYD, B. J., Passed Assistant Surgeon. Granted leave of absence for four days from November 22, 1907.
- NUTE, A. J., Acting Assistant Surgeon. Granted leave of absence for ten days from December 21, 1907.
- OAKLEY, J. H., Passed Assistant Surgeon. Reassigned to duty at Fort Townsend Quarantine Station, Washington, effective May 28, 1907.
- PARKER, H. B., Passed Assistant Surgeon. Reassigned to duty at Ellis Island, New York, effective December 7, 1907.
- ROSENAU, M. J., Surgeon. Granted leave of absence for six days from December 26, 1907, under paragraph 189, Service Regulations.
- RYDER, L. W., Pharmacist. Granted leave of absence for six days from December 21, 1907.
- STEARNS, H. H., Acting Assistant Surgeon. Granted leave of absence for nine days from December 7, 1907, on account of sickness.
- THOMPSON, W. R. P., Acting Assistant Surgeon. Granted leave of absence for twenty-one days from December 11, 1907.
- WILLIE, C. W., Passed Assistant Surgeon. Granted leave of absence for one month and twenty-two days from December 22, 1907.

## Promotions.

- BROWN, B. W., Passed Assistant Surgeon. Commissioned as surgeon, to rank as such from November 9, 1907.
- EAGER, J. M., Passed Assistant Surgeon. Commissioned as surgeon, to rank as such from November 9, 1907.
- FOSTER, A. D., Assistant Surgeon. Commissioned as passed assistant surgeon, to rank as such from November 28, 1907.
- ROBERTSON, H. McG., Assistant Surgeon. Commissioned as passed assistant surgeon, to rank as such from November 26, 1907.
- ROSENAU, M. J., Passed Assistant Surgeon. Commissioned as surgeon, to rank as such from November 9, 1907.

## Army Intelligence:

*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending December 28, 1907:*

- COLE, C. LER., First Lieutenant and Assistant Surgeon. Now at Lawrence, Kan., en route to Fort Thomas, Ky., will proceed to Jefferson Barracks, Mo., for temporary duty at that post, and upon the completion thereof will proceed to Fort Thomas, Ky., as heretofore ordered.

DAVIS, W. T., Captain and Assistant Surgeon. Granted thirty days' leave of absence.

SNYDER, C. R., First Lieutenant and Assistant Surgeon. Granted five days' leave of absence.

## Navy Intelligence:

*Official List of Changes in the Medical Corps of the United States Navy for the week ending December 28, 1907:*

BROOKS, F. H., Assistant Surgeon. Detached from the *Adams*, when placed out of commission, and ordered to the *Montgomery*.

DELANCY, C. H., Passed Assistant Surgeon. Orders of December 18th revoked; ordered to continue duty at the naval recruiting station, Chattanooga, Tenn.

HOYT, R. E., Passed Assistant Surgeon. Detached from the Naval Hospital, Canacao, P. I., and ordered to the *Chattanooga*.

THOMPSON, J. C., Surgeon. Detached from the *Chattanooga* and ordered to Washington, D. C., and report to the Secretary of the Navy.

ZALESKY, W. J., Passed Assistant Surgeon. Detached from the naval recruiting station, Chattanooga, Tenn., and ordered to the naval recruiting station, New Orleans, La.

## Births, Marriages, and Deaths.

## Married.

AUERBACH—MILLICAN.—In El Paso, Texas, on Thursday, November 28th, Dr. Leo B. Auerbach and Miss Lillie Pearl Millican.

DECKMAN—GANTZ.—In New York, on Wednesday, December 18th, Dr. A. C. Deckman, of Boston, and Miss Ethel St. C. Gantz.

ZINKE—KENNEY.—In Leavenworth, Kansas, on Thursday, December 19th, Dr. Stanley G. Zinke, U. S. Army, and Miss Beulah Few Kenney.

## Died.

BIEGLER.—In Rochester, New York, on Sunday, December 22d, Dr. Joseph A. Biegler, aged seventy-five years.

BODINE.—In Louisville, Kentucky, on Wednesday, December 18th, Mrs. Laura M. Bodine, wife of Dr. J. M. Bodine, dean of the Medical Department of the University of Louisville, aged seventy years.

BUTTERFIELD.—In Manlius, New York, on Monday, December 16th, Dr. Edward F. Butterfield, aged eighty-one years.

COVERT.—In Ithaca, New York, on Wednesday, December 18th, Dr. James L. Covert.

GREEN.—In Louisville, Kentucky, on Tuesday, December 24th, Dr. James Green, aged eighty-five years.

HOFFMAN.—In Reading, Pennsylvania, on Thursday, December 26th, Dr. John Y. Hoffman, aged forty-nine years.

HUNTING.—In Albany, New York, on Sunday, December 22d, Dr. Nelson Hunting, aged seventy years.

JOHNSON.—In Blairstown, New Jersey, on Monday, December 23d, Dr. John C. Johnson, aged seventy-nine years.

JONES.—In Pittsburgh, Pennsylvania, on Saturday, December 21st, Dr. Matthew O. Jones, aged eighty-six years.

LASSAR.—In Berlin, Germany, on Monday, December 23d, Professor Oskar Lassar, aged fifty-eight years.

LINJER.—In Minneapolis, Minnesota, on Wednesday, December 11th, Dr. Ole Edward Linjer.

LIPPITT.—In Elmington, Virginia, on Friday, December 20th, Dr. Charles Edward Lippitt, aged seventy-eight years.

MORRILL.—In Assouan, Egypt, on Friday, December 27th, Dr. F. Gordon Morrill, of Boston, aged sixty-four years.

PEASEN.—In Chicago, on Thursday, December 26th, Dr. Joseph Peasen.

SMITH.—In Vincennes, Indiana, on Monday, December 23d, Dr. Hubbard M. Smith, aged eighty-seven years.

SMITHEY.—In Burkeville, Virginia, on Friday, December 20th, Dr. Frank R. Smithey, aged twenty-five years.

SPOONER.—In Republic, Ohio, on Thursday, December 19th, Dr. Harry K. Spooner.

WATERS.—In Boyds, Maryland, on Thursday, December 19th, Dr. William A. Waters, aged eighty-one years.

WEAVER.—In Syracuse, N. Y., on Wednesday, December 18th, Dr. Lewis F. Weaver, aged fifty-eight years.

#### THE VOICE AS AN INDEX TO DISEASES OF THE THROAT, NOSE, AND EAR.\*

By G. HUDSON-MAKUEN, M. D.,  
Philadelphia,

Professor of Defects of Speech in the Philadelphia Polyclinic Hospital and College for Graduates in Medicine; Laryngologist to the Frederick Douglass Memorial Hospital; Laryngologist to the Chester Hospital, Chester, Pa.

Some one has well said that the voice is the mirror of the man, meaning, of course, that it reflects man's character, his physical and even his moral and intellectual states. Every physician will agree with this proposition in so far as it relates to the physical condition, for who has not noted the weak and almost inaudible voice of the very ill person and observed its gradual strengthening during convalescence. Indeed, the general physical condition influences the voice to such a degree as to render obscure oftentimes certain definite lesions of the throat, nose, and ear, and this is a fact that should be kept constantly in mind in dealing with this subject.

But the moral state of the individual is also reflected in the voice. He whose business it is, for instance, to teach piety will unconsciously and undesignedly acquire a pious tone or the so called ministerial voice. The physician, whose function it is to comfort and heal the sick, will develop a sympathetic voice, and the lawyer, the colder and more judicial tones.

Moreover, culture and refinement are reflected in the voice, and the lack of these acquisitions are no less apparent. The good man, as a rule, will have a good voice and the bad man can with difficulty conceal his badness when he speaks.

The nervous states are also reflected in the voice. The high, thin voice of the nervous type of man is in striking contrast to the lower and heavier voice of the more phlegmatic type.

Good morals and good vocalization, however, do not come by nature, but they are the results of education and training, and this fact has a very practical bearing upon the subject under consideration. Skill in the use of the voice may temporarily and effectively render obscure certain abnormal and even diseased conditions of the throat, nose, and ear, as it may occasionally conceal the evil in one's character. For instance, every practitioner of our specialty doubtless has been surprised at one time or another to find large tonsils, relaxed palates, and

elongated uvulas in the throats of good and even famous singers, obstructions that have been almost entirely overcome by skill in the use of the vocal organs. The question of training, therefore, or the lack of training, must be considered in studying the voice as an index to the diseases of the respiratory tract.

The various kinds of voice that we think of in connection with this subject are the hoarse, the throaty, the tremulous, the muffled, the whispered, the falsetto, and the nasal voice. The hoarse voice is always pathognomonic, of either intralaryngeal disease or an intralaryngeal expression of some disease of the central nervous system. It varies in degree all the way from the scarcely perceptible hoarseness of the beginning laryngeal involvement of a common cold, to the marked hoarseness of an acute laryngitis immediately preceding the aphonic stage, when only the whispered voice is possible. The hoarseness of the various stages of acute laryngitis is due not only to the inflammatory thickening of the cords, but also to the general tumefaction of the laryngeal mucous membrane, making it impossible oftentimes for the cords to assume the normal position during vocalization. A common cause for the characteristic hoarseness of incipient tuberculosis is the thickening of one or both of the ventricular bands, which interferes with the normal approximation and vibration of the cords. An illustrative case of this condition is one that I exhibited recently at a meeting of the Section in Otology and Laryngology of the College of Physicians in Philadelphia:

The left ventricular band was about twice the size of the other normal one. The young woman's hoarseness was only incidental, to her own mind, to a form of stammering which has annoyed her for years, but it was quite intractable and did not yield to any form of treatment. She had a morning cough with slight expectoration, but there were no characteristic bacilli. The chest signs were only "somewhat suspicious," to use an expression of Dr. Eshner, who also examined the patient. The local treatment now in my hands consists in the application of mild astringents to the larynx, the use of breathing and light calisthenic exercises, and the usual training and practice for the improvement of the voice and speech. This particular patient, in my opinion, can only be saved from the ravages of the dread disease, tuberculosis, by the strictest hygienic measures, and by the practice of well chosen respiratory and vocal exercises.

Hoarseness is also symptomatic of intralaryngeal tumors, both malignant and benign, and the character of the hoarseness will often suggest to the practitioner the probable nature and location of the tumor. A case for diagnosis, however, is a small boy now under my observation.

He is four years of age and has never used his normal voice since birth. He is a very intelligent and bright child.

\*Read before the Academy General Session, at the Academy of Ophthalmology and Otolaryngology, held at Lancaster, Pa., September 26, 27, 28, 1907.

He inherits a nervous disposition, with a history of consumption on his father's side. His tonsils are imbedded and slightly enlarged, and a satisfactory rhinoscopic or laryngoscopic examination has not been possible. I confess that I am in doubt as to the condition of the larynx that gives rise to this peculiar voice. Whatever it may be it has existed for several years, and it is only recently, with some little persuasion and training, that he has used the resonant voice at all, and even this is very hoarse. My first thought was of papillomata, but after a further study of the case I am quite in doubt as to the diagnosis. In the attempts to get a laryngoscopic image of the larynx I have found the epiglottis hanging low and folded upon itself. The use of the mirror seems to give him considerable discomfort and some dread of total obstruction to respiration. There is no history of dyspnoea, but only of acute colds, during which vocalization is so difficult that he practically refrains from talking at all. I have not yet tried direct laryngoscopy, and the symptoms have not been sufficiently urgent to warrant etherization.

Intralaryngeal ulcers, especially those having infiltrated edges with copious secretions, are productive of a sort of moist hoarseness which is quite different from the hoarseness of a comparatively dry larynx.

The tremulous or broken voice is characteristic of very old people, but we find it also in those who are debilitated by overwork, and especially by extraordinary vocal effort. It is the voice of broken-down and worn-out clergymen. I have recently had two such cases under my care. They are described in the literature as "disphonia spastica." There is a nervous element in the condition similar to that which we find in stammering. The voice wavers in the glottis most unexpectedly at times, and the patient knows neither its cause nor its remedy. Moreover, he is in constant dread of its reappearance. It becomes a nervous habit, a veritable fear neurosis, and it is often accompanied by peculiar psychic disturbances. The oropharynx and larynx are normal except for a marked hyperæsthesia of the mucous membrane, making a laryngoscopic examination almost impossible. In one of my cases the tremulous voice alternates with complete aphonia, making a most curious admixture. Somewhat akin to this condition is one illustrated by a young man now under observation who has a peculiar catch in his voice, with a hesitation of speech, due to intermittent unilateral paralysis of the abductor laryngeal muscles. Although this condition of the larynx is rarely met with in stammerers, it is one that we should be on the lookout for and one that may be very easily overlooked.

The whispered voice is well illustrated in hysterical aphonia, in which there seems to be a sort of paralysis of the abductor muscles, and it appears also in acute laryngitis where there is a mechanical obstruction to the normal action of the cords. Of course any one of the defective types of the voice which I have mentioned may be and often is aphonic. A curious example of this condition is that of the small boy to whom I have referred. In the majority of cases of hysterical aphonia there have been, in my experience, local conditions which have shared in the sum total of the causal factors. Acute laryngitis, for instance, may be the original cause and the hysterical element a subsequent development. This emphasizes the importance of a careful examination of the larynx in all so called hysterical aphonias. It should be remembered that

hysteria is generally an acquired psychological condition and often the result of a simpler local condition.

The voice of the deaf is particularly characteristic. It has a high pitch and it is monotonously throaty. It is an unmodulated voice, owing to the fact that the deaf cannot hear themselves speak. The exact degree of deafness in children may be exceedingly difficult to determine, and the character of the voice is often our only guide. The child that is only partially deaf will modulate the voice, while the totally deaf child will speak, if at all, in high monotonous and throaty tones. This fact is of great practical and diagnostic importance. Only the other day I saw at my clinic a child that had been at a State institution for the deaf for nearly a year and sent home again, because it was found that she had some hearing, a fact that was discovered only after a considerable experimentation. The child with a congenital deficiency of hearing will, as a rule, be backward, speak little, if at all, and that little will be defective and contain only those sounds that it happens to hear. On the other hand, the congenitally deaf child, of course, will not speak or phonate at all, until it is especially trained to do so. The adult person who has acquired partial deafness will generally speak loudly, although he censures others for speaking too loudly. What helps him most to hear is distinctness of articulation.

The muffled voice is one that is more or less devoid of head resonance. It is the voice of those having faucial and pharyngeal tonsils, hypertrophied turbinates, nasal polypi, or other nasal and pharyngeal growths. The nasopharyngeal resonators are dampened, so to speak, and the voice is muffled.

The falsetto voice is generally indicative of no special throat, nose, or ear lesion, and it is due entirely to an erroneous conception of the true tones and a consequent misplacement of the tones. There is in it no laryngeal or chest resonance, but the larynx is markedly elevated and the vibrations are focused high up in the head.

The nasal voice is due in the majority of instances to inadequacy of the velum palati, which allows too great a proportion of the vibrating breath to pass up through the nasopharynx, thus giving a preponderance to the nasal resonance. This is well illustrated by two patients who have recently come under my observation—one a woman of twenty-four and the other a boy of nine years. In neither case is there a sufficiency of action in the levator palati muscles during the process of speaking. In that of the small boy there is no action of these muscles whatsoever, and they do not respond even to electrical stimulation. Curiously enough, there is no history in either case of an infectious disease to account for the parasis, and the character of the voice is the only symptom of the condition. The voice in these patients is strongly suggestive of a cleft palate.

The purpose of this paper is to demonstrate the importance of the voice as a factor in diagnosis and to emphasize the necessity for a more critical study of the voice, especially in its relation to diseases of the throat, nose, and ear.

1627 WALNUT STREET

# THE ADVANTAGES OF SANATORIUM REGIME IN TUBERCULOSIS, WITH ESPECIAL REFERENCE TO THE TREATMENT OF EXTRAPULMONARY LESIONS.\*

By F. M. POTTENGER, A. M., M. D.,  
Monrovia, Cal.,

Professor of Clinical Medicine, Medical Department of the University of Southern California.

I shall endeavor to confine my remarks, for the most part, to the treatment of tuberculous lesions found in organs other than the lungs. But, inasmuch as many of these lesions exist as complications of tuberculosis of the lungs, and inasmuch as tuberculosis is the same disease wherever found, it will be necessary to discuss the treatment of tuberculosis in general to some extent.

In order to have the proper conception of these extrapulmonary lesions, we must bear in mind that tuberculosis is the same disease wherever found. The various manifestations differ only in that different organs are affected; the cause is the same, and the result from a pathological standpoint is the same. The pathology of tuberculosis of the kidney and bowels is the same as that of the lung and larynx.

Tuberculosis is a disease produced by a specific microorganism, and its cure, like that of all other infectious diseases, is brought about by the establishment of immunity. I do not mean immunity in that narrow sense whereby the term is usually understood as denoting an impossibility upon the part of an individual, either temporarily or permanently, of becoming infected; but immunity in that broader sense which means a degree of resistance whereby the organism through a response which is made upon the part of its tissue cells in reacting to the stimulation of some toxine, produces defensive bodies which have as their specific function the destruction of that toxine.

The symptoms of tuberculosis are produced, in part, by the tubercle bacilli and, in part, by the toxins which are produced by the bacilli and poured out into the circulatory fluids of the body. Its cure must come from the establishment, upon the part of the infected organism, of an immunity to both the bacilli and their toxins.

It has been shown that the action of the tubercle bacilli and their toxins is different, the former tending more to the production of fibroid tissue, the latter more to the production of necrosis. Hence, whether healing or necrosis shall occur, the resisting power of the patient being the same, depends very much upon the amount of toxine present. An infection caused by very virulent bacilli or by great numbers of bacilli pours out into the circulation a toxine of greater potency and toxine in great amounts and consequently causes necrosis, while an infection caused by bacilli of a less virulent strain or by a smaller number of bacilli is more apt to be followed by the formation of fibroid tissue and result in healing.

In support of this statement I would cite the fact that dead bacilli which are not producing toxins are more apt to be followed by the formation of fibroid tissue than the same bacilli when alive;

and the even more convincing experiments of Störk (*Wiener medizinische Wochenschrift*, July, 1907) whereby he has been able to produce fibrosis in 100 per cent. of pigs by injecting them with a culture of tubercle bacilli of low virulence.

This, then, gives us the key to the treatment of tuberculosis, which is to do all we can to lower the virulence of the infecting bacilli and to counteract the effect of and destroy their toxins. Anything which will do this must do it by the production of specific protective or immunizing bodies. These bodies are produced by the body cells themselves; therefore any measure or measures which will improve the nutrition of these cells and make them capable of producing more antibodies, or any products which will stimulate these cells to the production of more antibodies, will aid in bringing about a cure. It is needless to say that, aside from these, all distressing symptoms should be treated in the proper manner.

It can readily be seen, then, that fresh, pure air, good food, carefully regulated rest and exercise, hydrotherapy, suitable tonics, and favorable climatic conditions act by giving the patient well nourished cells, so that he is capable of responding in such a manner as to produce a maximum quantity of antibodies when the proper stimulus is afforded. The stimulus which is required to act upon the cells to cause them to produce these immunizing bodies is furnished in all infections by the specific germ causing the infection, and this can be furnished artificially as well as by natural infection. The introduction of dead germs or their toxins stimulates the cells to the production of immunity. In tuberculosis, by artificially introducing products made from the tubercle bacillus we are able to stimulate the cells to the production of two or three times as many protective antibodies as they will produce without this stimulation. The real scientific cure of tuberculosis, then, consists in building up the patient, making his cells capable of responding to the production of as many antibodies as possible, and then introducing some product made from the tubercle bacillus, such as tuberculin, bacillus emulsion, or bacillus extract, which will artificially stimulate these cells to the production of a maximum amount of these immunizing bodies.

The cure of tuberculosis is slow. Unlike the acute infections, which run their course in a few days or a few weeks, tuberculosis lasts for months and years. As its pathology indicates, it cannot heal rapidly. This fact adds to the difficulty of treatment and makes results much less satisfactory than the disease itself warrants.

Patients suffering from tuberculosis, even in the advanced stages, feel well a goodly portion of the time. This fact reacts against them and prevents them from having the best chance of cure, because during this time they tax their systems by doing foolish things. When acutely ill, as with typhoid fever or pneumonia, the patient feels so sick that he goes to bed and sends for his physician; when afflicted with tuberculosis, on the other hand, he manages his case alone or with the advice of a host of friends and neighbors and perhaps with a few indefinite instructions from a physician. Thus the tuberculous pa-

\*Read before the Kings County Medical Society, at a meeting held at Seattle, Wash., on October 7, 1907.

tient is usually badly managed, he goes from bad to worse, and nearly always dies of his disease.

That such a result should occur when so serious a disease as tuberculosis is treated in so unscientific a manner is a foregone conclusion; but such a result is entirely unnecessary, for tuberculosis is a disease which yields to rational, scientific treatment. Does it not seem almost beyond comprehension that the members of the medical profession should give careful attention to detail in treating the ordinary petty illnesses that make up a considerable portion of every man's practice and then turn the same patient away to rely on himself or the advice of his neighbors when he becomes afflicted with one of the most serious of all diseases? This apparent neglect, however, springs from and is a monument to the honor of the medical profession. The members of our profession have considered tuberculosis as hopeless, and have felt that they were helpless in undertaking to treat it, and rather than take money from patients to whom they felt unable to render competent service they have told these unfortunate sufferers that they could do nothing for them, and thus they have cast them adrift to find help or harm for themselves.

It is now time that the honor of the medical profession demands a change in its attitude. Tuberculosis is now known to be a curable disease. During the past fifty years, but more particularly the past ten years, favorable reports on the treatment of this disease have been accumulating, and now we can say it is the most curable of all chronic diseases.

The most favorable results in the treatment of tuberculosis have been produced in sanatoria, especially conducted for the purpose, and the results in these institutions vary greatly according to the conditions under which treatment is carried on and the methods employed. Thus the result in early cases ranges from 65 to 95 per cent. of apparent cures; in moderately advanced cases from 10 to 65 per cent., and in far advanced from none to 20 per cent.

When we compare these results with those obtained in treating tuberculosis in the usual ambulatory manner we can see that the results are almost beyond credence.

It is well for us to inquire, then, why sanatorium treatment offers such superior advantages in treating tuberculosis. Why is it necessary to send patients who do not seem or feel ill to an institution for treatment? Why especially should those who are in the early stages of the disease be sent to sanatoria? A glance at statistics from institutions where all stages of the disease are treated should answer the question, for these show that where early cases can nearly all be cured, later cases are cured with difficulty, and the very late nearly all die. But figures are not always convincing and sometimes remain to be explained.

Tuberculosis is a disease which heals slowly, and, as explained before, one whose healing depends upon the resisting power of the patient. There is a constant tendency for the disease to spread to new areas, and upon this fact, together with the complications resulting from it, the life of the patient depends. The greater the area of involvement the greater the opportunity for bacilli to escape and cause new foci, and the more detrimental the ef-

fect on the system; hence the more serious the disease. Whether or not the bacilli which escape from the foci of infection shall cause a new infection and whether or not the old infection shall heal depends upon the resisting power of the patient. A patient whose resisting power is good—that is, one whose cells respond to the stimulation of the toxins resulting from the presence of the invading bacilli, by the production of a large amount of antibodies, will, unless the virulence of the bacilli be too great, offer a strong resistance to the disease process present as well as a barrier against the bacilli which attempt to form new foci. On the other hand, one whose resisting power is low or oscillating between high and low is offering the disease focus new opportunity to progress and affording a very uncertain barrier to the extension to new areas.

The application is obvious to all. The tuberculous patient's resisting power must be kept as high as possible during the entire course of treatment. His protective antibodies must be constantly stimulating the old foci to healing and must be ever on guard to destroy bacilli that may be thrown into the circulation and go to form new foci in other tissues. This can only be offered by putting him under conditions which are especially directed to this end.

That it is possible to largely prevent this spread of infection has been strongly impressed upon me by my experience in treating advanced cases of tuberculosis. While about half of those who enter the institution have an involvement on the part of the larynx, and while a large percentage have symptoms of tuberculosis of the bowels, yet it is rare for these patients to develop such complications after they are put upon the hygienic dietetic and tuberculin treatment, unless it be a part of a terminal general military infection.

Our so called civilized methods of living are unnatural and, from the standpoint of health, barbarous. It is almost impossible for an individual suffering from tuberculosis to live in homes and boarding houses, and live a true hygienic life. Well people will not put up with the so called deprivations which are necessary for a tuberculous patient who is trying to live a hygienic life; neither, as a rule, will they allow him to do it. Rather than encourage him as they should, friends, as a rule, say "once breaking the rule will not harm," and urge the doing of those things which carry more or less risk.

The only successful way to keep the resisting power of these patients at a high stage long enough for them to overcome the disease is to place them in the proper surroundings, remove them from temptation, and then keep them interested in the cure until it takes place.

It is needless to say that such a method offers not only greater chances of cure, but the opportunity of obtaining the result in a much shorter time. Sanatorium treatment offers about 50 per cent. better chances of cure than ambulatory treatment and produces the result in a shorter time.

Another bad feature about treating tuberculous patients outside of sanatoria is the danger of secondary infections. Acute colds, bronchitis, la grippe, and pneumonia, like the poor, we always have with us. These are dangerous, and often fatal, enemies of the tuberculous patients; especially when

they are living in homes and boarding houses and associating with people in general, there is always more or less exposure to them, while in sanatoria such exposure is largely eliminated.

But even aside from these advantages of the sanatorium treatment the greatest advantage is that this method brings the patient under the direct control and constant guidance of the physician, where he can correct all things which tend to tear down and apply remedial measures that are of value in the most advantageous manner. Complications are seen and treated in their incipency, accidents are prevented, troublesome symptoms are relieved, and the cooperation of the patient is secured as cannot be attained in any other manner.

For many years medical science has recognized the curability of tuberculosis of the bones and joints. To a certain extent the curability of glandular tuberculosis has been accepted. Gradually it has been recognized that the pulmonary form is amenable to treatment, and evidence is forthcoming to show that all forms are sometimes curable and that many of those which have been considered hopeless are fairly readily healed by appropriate measures.

The curability of forms of tuberculosis other than pulmonary (save those of the bones, joints, and glands) has been established by sanatorium treatment. Such complications as tuberculosis of the larynx, upper air passages, urogenital organs, and even that of the bowels, will yield to appropriate treatment when carried out as it is done in properly conducted sanatoria. The cure of these may justly be said to be the contribution of private sanatoria to the curability of this disease. Public and philanthropic sanatoria have for years refused to take patients who were suffering with these complications, but private institutions have taken them and through persistent effort succeeded in curing many of them. When I speak of their curability, I do not wish to minimize the difficulties attendant upon treating such cases, for they are great; but the fact that they can be cured at all is a triumph of modern medical science. I wish now to discuss several of the most common forms of tuberculosis as we find it situated in organs other than the lungs, and endeavor to show some of the more hopeful aspects of their treatment.

#### *Tuberculosis of the Upper Air Passages.*

The most common form of tuberculosis other than pulmonary that we are called upon to treat is tuberculosis of the larynx. The larynx is involved much more commonly than is generally supposed. Careful post mortem observations on patients who have died of tuberculosis, and careful routine clinical examination of the larynx in patients who are suffering from advanced tuberculosis, show that more than 50 per cent. of patients in the advanced stages have some involvement of the larynx.

Unfortunately the tuberculous larynx is not diagnosed early. If the patient presents himself to the physician complaining of hoarseness and cough, and, upon examination, the larynx is found to show thickening with congestion of some portion, either the cords, the interarytenoid space, the arytenoids, or the ventricular bands, he is too apt to be treated for simple laryngitis. A tuberculous nature is not

suspected until there is breaking down with ulceration.

When we recall our pathology, we remember that ulceration does not occur as a primary condition. Only after infiltration has existed for some time does necrosis occur; consequently we must not look for ulceration, but we must learn to diagnose tuberculous laryngeal involvement early, during the infiltration stage.

The stage of infiltration lasts during a variable time. It may be a few weeks, in very virulent infections, or it may be months in less virulent infections, or it may never occur. I have known it to last for several years without ulceration occurring.

There is one point that should be insisted on in all cases where such suspicious conditions are found upon physical examination, and that is the establishment or elimination of tuberculosis elsewhere in the body and especially in the lungs. A careful expert physical examination will nearly always settle this matter very easily, and if there should be any doubt remaining a tuberculin test will show the local reaction and clear up all doubt.

Tuberculosis of the larynx is perhaps always secondary to tuberculosis elsewhere and nearly always secondary to tuberculosis of the lungs; and, while I recognize that all pathological conditions such as I have mentioned occurring in individuals afflicted with tuberculosis are not necessarily tuberculous in their nature, yet facts warrant us in suspecting all such cases and demand that a diagnosis be made.

Remembering that more than 50 per cent. of advanced cases of pulmonary tuberculosis show some infiltration in the larynx, our attention is called to this as being a very common complication and one for which we should always be looking.

Routine examination of the larynx should always be made at frequent intervals in all patients who are suffering from tuberculosis of the pulmonary form, and careful examination of the chest should be made where infiltration presents itself in the larynx, and if doubt still remains the local tuberculin reaction should be looked for.

The administration of the tuberculin test in laryngeal cases requires a knowledge of the action of tuberculin and an ability to examine the larynx. The reaction here nearly always shows early. A fever reaction is rarely necessary. Following the injection of the remedy, an increased congestion in the larynx occurs if the involvement is of a tuberculous nature; if it is not, no change is seen. The dosage in tuberculous laryngitis should begin with 0.1 to 1.0 milligramme, the same as is used for the tuberculin test in general. It is rarely necessary, however, to give as large doses as are required for a general fever reaction. One tenth to 1, 2, or 3 milligrammes will nearly always decide the diagnosis.

When tuberculosis of the larynx has been discovered, what prognosis can we give the patient? This depends, like tuberculosis of the lungs, upon the earliness of the diagnosis and the nature of the treatment instituted. Another important factor to be considered is the condition of the lungs. If the pulmonary condition is not too serious and the diagnosis is made early, the chances of cure with proper treatment are very good.

No doubt many cases of slight laryngeal involve-

ment are healed without either patient or physician knowing of their presence, but it is not safe to rely on such good fortune. Tuberculosis of the larynx calls for skillful, intelligent treatment, and of all measures which offer chances of cure I believe there is none equal to the inoculation of the patient with products made from the tubercle bacillus. In fact, the cure of this malady has been established by the use of tuberculin and its allies.

Tuberculosis of the larynx must not be treated as an entity, but as a part of the tuberculous process which affects other organs, nearly always the lungs.

This is the ideal place for tuberculin treatment, because the reaction is visible. The dosage should be so measured that only a slight reaction is caused, and it should not be repeated until all local signs have disappeared, and the dose should not be increased in amount until the amount which caused the reaction fails to produce local signs.

Aside from these bacillary products, the patient should have the benefit of all advantages that the sanatorium affords, such as open air, good food, properly regulated rest and exercise, hydrotherapy, and other tonic measures.

Locally, palliative measures only should be used. The parts should be kept clean and may be slightly stimulated by protargol or some such application. If ulceration is present, these measures are sufficient unless pain be a symptom, when the application of orthoform, or if cough is also troublesome, orthoform with 1/12 to 1/6 gr. of heroine may be used. The heroine should not be used unless absolutely necessary.

A cold compress to the throat relieves much of the cough.

Such measures as curettage and lactic acid are of little value as curatives. In fact, local applications must not be expected to cure the disease, nor must the physician flatter himself with a hope that he may remove all the tuberculous tissue by excision, for such is almost an impossibility, as has been shown by the return of the trouble in nearly all cases where these measures have been employed.

The cure must come about by stimulating the body cells to the production of sufficient immunizing elements or antibodies to overcome the action of the bacilli and their toxins.

Aside from tuberculosis of the larynx, we find infections of the pharynx, tonsils, tongue, and nose. All of these are curable in a certain proportion of cases, but they require constant watching and persistent treatment for a long period of time in order to accomplish the results. Favorable reports on such lesions are rarely obtained except in sanatoria, because it is almost impossible to give the required attention and impossible to hold the interest and co-operation of the patient except by the constant intimate association of the patient and physician.

#### *Glandular Tuberculosis.*

Tuberculosis of the glands is a form that needs careful consideration. In tuberculosis, the glands perhaps always play a part. In many instances they are infected, although they do not break down. These enlarged glands, however, cannot be looked

upon with unconcern, for they are centres of infection, and we know not at what time bacilli will be thrown out into the general circulation and be carried and deposited in some other organ, where they may start an active tuberculosis.

For years excision has been the recognized treatment for such glands, but it has rarely been employed until the glands have shown some sign of breaking down. Such a procedure is irrational, because in the first place the danger from tuberculous glands begins before the glands show signs of softening, and in the second place, by removal, only those glands which are found at the site of the operation are removed, while, as a rule, others are left behind, which often go on to softening; or, if they do not, remain as foci of infection from which the disease may spread to other organs.

Of the many patients whom I have treated in the past few years, many have had enlarged cervical and axillary glands, but in not a single instance has suppuration occurred. These usually respond to treatment by becoming smaller and assuming their normal size, or, if they are the seat of new tissue formation, they become smaller and remain as fibroid nodules.

Recognizing the frequency of tuberculosis of the glands in children, and knowing that tuberculous infection commonly affects the glands before it spreads to new tissue, I believe the time will soon come when we will treat the tuberculosis of children while it is still confined to the glands and before other vital organs are infected. The glands are the ideal place for the treatment of the disease, because the lymph, with its antibodies, comes in direct play upon the bacilli and their toxins. It is better to remove a bomb from under a house before it is lighted than to patch up the house after the bomb has exploded.

#### *Tuberculosis of the Genitourinary Tract.*

Experience with tuberculosis of the genitourinary tract is encouraging. I have seen tuberculosis of the kidney heal. The application of tuberculin to infection of the bladder and testicle is also offering good results when properly administered. We have had a unique experience in the institution I am connected with, so far as I know, in the way of an apparent cure of a tuberculous ovary.

The history of the case is as follows:

Two years previously the patient had been operated upon by a Seattle surgeon, at which time one ovary was removed. This proved to be tuberculous. The surgeon gave the opinion at the time that the other ovary would require removal later because it also showed signs of infection. Owing to a promise to the patient that only one would be removed, the second ovary was left. Immediately before coming to us the same surgeon examined the patient and advised removal of the remaining ovary, but instead the patient preferred to make an attempt to save the organ. She came to us and insisted that we should treat her. We informed her that we had never treated such a case, and could not promise any success; but she urged a trial.

Examination showed the ovary to be much enlarged and very tender. There was also a slight lesion in the lungs.

The patient was admitted to the sanatorium and treatment was begun. She was put upon the ordinary régime and given tuberculin. After one year's treatment the pulmonary condition was apparently cured, the ovary had reduced in size, all tenderness had disappeared, and it gave the impression of being healed. Owing to the inflammatory

condition present, adhesions formed which at first gave her some trouble. About six months after leaving the institution she became anxious about the matter and visited a physician who gave it as his opinion that the trouble was active again and that the ovary should be removed. She again came to the institution for examination, which showed the result the same as it was upon leaving. She was given large doses of tuberculin without any reaction whatever. It is worthy of note that during the course of treatment large doses of tuberculin often caused congestion with decided pain in the ovary. Her condition remains good and it appears that a cure has been effected.

#### *Intestinal Tuberculosis.*

Perhaps tuberculosis of the intestines is the most serious form of the disease. This is almost always a complication of the pulmonary form. It is more common than is generally believed, being found as a complication in from 50 to 80 per cent. of all cases of tuberculosis which come to autopsy.

This condition is often present without being recognized. It is usually thought that tuberculosis of the intestines manifests itself by diarrhoea. This is not necessarily true, in fact, whether or not diarrhoea is present depends very much upon the location of the lesion. There are two principal locations for tuberculosis of the intestines, one in the ileum in the region of the caecum, the other in the lower bowel near the rectum. The former may not manifest itself at all by diarrhoea, but in the latter the diarrhoea is often intractable.

The diagnosis is not as difficult as is generally believed. The patient should be cautioned carefully about swallowing sputum, then after forty-eight hours a sample of feces should be collected and examined. Feces may be examined by making a smear from a small particle, or a small particle may be taken, mixed with twenty times its volume of water, and centrifugized so as to throw down the coarser particles. The upper fluid is then poured off, mixed with twice its quantity of alcohol and centrifugized again, when the sediment is examined.

When tuberculosis of the intestines has been diagnosed, the patient should be treated most carefully. A liberal diet should be allowed, but one which will nourish without throwing extra burden upon the intestinal tract. Overfeeding should not be carried out—in fact, it has very little place in the treatment of tuberculosis of any kind. The bowels should be kept open and free from irritation. Where constipation is present, I have found olive oil, one teaspoonful to one tablespoonful after meals, to be valuable, with an occasional dose of castor oil if necessary.

When diarrhoea is present I open up the bowels at once with castor oil, and put the patient on a restricted diet, consisting of milk and vichy or the whites of eggs. If after a day the patient's condition is better, I gradually add milk toast, boiled rice, scraped meat, and tropon. Applications of hot cloths to the abdomen, changed every twenty minutes and kept up for one or two hours at a time, gives great relief to the patient and helps to control the trouble.

If the diarrhoea is intractable, high enemas of hot normal saline solution or of starch water and bismuth, or starch water and opium, may be used to advantage. In these cases the internal administra-

tion of bismuth from x to xxx grs., either alone or combined with from v to x gts. of deodorized tincture of opium, should be tried if the other measures are unsuccessful. As a last resort, there is perhaps nothing better than lead and opium, but I should not recommend it unless the others have failed.

By handling the occasional symptoms which are produced by the less serious infections of the intestines in the manner mentioned and giving the patient the benefit of rational treatment, as suggested in the early part of the paper, the disease will sometimes heal. I have seen several cases heal where the symptoms were pronounced and where diarrhoea with pain in the abdomen followed tuberculin reactions, thus confirming the diagnosis. While I look upon this as a most serious complication, yet I think that we have reason to believe that ere long we will have evidence enough at hand to show us that this condition is also occasionally amenable to treatment.

In the preparation of this paper I have simply given my own experience. The class of patients that come to us are, as a rule, far advanced in the disease. They have tried fresh air, and all the usual remedies, they have given various climates a trial unsuccessfully, and then when they have arrived at an advanced condition, with very often complications on the part of the larynx and bowels, they are ready for sanatorium treatment. While this has made our work difficult and precluded the possibility of obtaining the best results, yet it has afforded us an opportunity to study these complications, which have resulted in the evidence which I have placed before you.

And why should these tuberculous complications not heal? Tuberculosis has the same cause and same pathology wherever found. It is cured by the same measures wherever found. If cured at all it will be cured by raising the power of the body cells to the place where they will produce sufficient antibodies to overcome the infection, as I have shown; so, we must either assume that these complications are more virulent than the infection in the lung or expect them to yield to rational treatment.

I would not counsel delay until these various complications result, but insist on an early diagnosis and prompt intelligent treatment; but the point that I wish to make is, that a man does not need to be condemned to death because of some other organ than the lungs being involved as a complication of pulmonary tuberculosis, and especially is this true when the diagnosis of the complication is made early.

One word about tuberculosis of the bones and joints before closing. If we may judge from the after history of these cases we must admit that the results obtained by the ordinary operative and mechanical measures are not quite as good as can be desired. Very often secondary infection of other organs follow these primary lesions. The leaders of thought along this line are now beginning to suggest that their patients be given the benefit of sanatorium and tuberculin treatment along with the other measures. It is certainly rational and will doubtless add much to the permanency and thoroughness of the result.

## ACUTE PULMONARY ŒDEMA AS A COMPLICATION OF EPILEPTIC SEIZURES.\*

BY WILLIAM T. SHANAHAN, M. D.,  
Soneya, N. Y.,

First Assistant Physician, the Craig Colony for Epileptics.

The complication of a grand mal seizure mentioned in this short paper is that of a pulmonary Œdema which is sudden in onset and produces a serious condition in all instances and in some cases a fatal termination. In some cases this Œdema is recurrent. This state is one to which little or no attention has been called in treatises on epilepsy, although seen fairly frequently.

Riesman, in an excellent article in the *American Journal of the Medical Sciences*, January, 1907, has given a résumé of the literature on the subject of pulmonary Œdema and reports six cases of an acute recurrent form.

He mentions this Œdema as being associated with arterio sclerosis, Bright's disease, heart disease, angina pectoris, asthma, acute infectious diseases, pregnancy, paracentesis of thorax and abdomen, angioneurotic Œdema, and finally with obscure conditions of questionable causal relationship, such as hysteria, etc.

In every grand mal and in many petit mal seizures there is a more or less marked increase in the secretion of mucus along the respiratory passages with the subsequent frothing at the mouth which is commonly seen in such patients. In some cases there may be no actual increase, but simply an accumulation in the mouth of the normal amount which is then forced from between the lips during the accentuated respiratory air currents which accompany the stertorous type of breathing.

In a few cases this great outpouring of mucus becomes so marked that the patient is in actual danger of being drowned in his own secretions, this acute process producing a marked pulmonary Œdema. The acute Œdema should not be confounded with the frequently occurring terminal Œdema seen in many epileptics, as well as those suffering from the many other diseased states which have already been mentioned. In a large proportion of the autopsies done on patients who had died at the colony, a terminal pulmonary Œdema has been found.

The patients observed have been in fairly good physical condition preceding the occurrences of one or more grand mal seizures. During the stertorous period of the isolated seizure, or perhaps the second or third in a series of seizures, there suddenly appears an outpouring of mucus, perhaps blood tinged, from the mouth and nose, with a marked cyanosis and dyspnoea occurring concomitantly.

*Ætiology.*—Some of these cases occurred in patients who had an affection, which in all probability acted as a predisposing cause, but would never have been sufficient to have brought about the Œdema unless the circulatory changes accompanying the epileptic seizure had been added to it. Of the eleven cases reported in this paper, seven patients recovered and four died. In three patients the condition recurred, and in one of them the second period observed was fatal.

Dr. William H. Welch's theory of the cause of pulmonary Œdema is as follows:

A disproportion between the working power of the left ventricle and of the right ventricle of such character that, the resistance remaining the same, the left heart is unable to expel in a unit of time the same quantity of blood as the right heart.

An enfeebled action of the left ventricle, rather than a spasmodic action, is likely to be the cause of this disproportion under the conditions in which pulmonary Œdema ordinarily occurs. As a consequence of this there is soon a large excess of blood in the pulmonary vessels. The Œdema is one usually associated with venous hyperæmia. An increase of the intracapillary pressure is brought about in the lungs, and perhaps a decrease of the extracapillary pressure, or both. The asphyxia accompanying the seizure is caused by the local stagnation of the blood stream and in turn causes an increase in the permeability of the endothelial wall of the capillaries of the lung.

*Treatment.*—The most important procedure has been found to be a change of posture so as to aid in draining the respiratory passages of the great excess of mucus. If necessary, turn the patient over the side of the bed, removing all mucus from the mouth, nares and pharynx. Open the mouth with a gag or with the fingers protected by a towel. In addition, much benefit has been obtained by dry cupping and the use of atropine and strychnine hypodermatically. Venesection is of value in full blooded patients. Adrenalin was used without apparent result.

CASE I.—M. B. T., female; admitted to the Craig Colony May 22, 1899; age, twenty-seven years. Onset of epilepsy at seven years. Had both petit mal and grand mal seizures. Well nourished woman. At time of admission physical examination revealed a mitral murmur.

July 13, 1903.—She had a grand mal seizure, following which a marked acute pulmonary Œdema occurred. A venesection was done and patient quickly improved. Recovery uneventful.

December 6, 1906.—Slight bronchitis had occurred at intervals during past year. General health had been good, so that she worked in laundry regularly. At 1:15 a. m. she had a severe seizure, which was following by a marked cyanosis of face, dyspnoea, and elevation of temperature, 103° F. Examination of chest showed numerous dry râles, with some moist râles. There was some bloody saliva and mucus expectorated from time to time. Great restlessness and fear of death. She was turned on her side with head hanging over edge of bed, so that fluid would drain from air passages. Given atropine gr. 1/60 hypodermatically and dry cupped over entire right chest. In half an hour patient was quieter and dyspnoea much less marked. Pulse was of good volume, but not of particularly high tension. Moist râles were present for three days, after which she returned to her usual state of health.

CASE II.—H. J. L., male; admitted April 9, 1898; age, thirty-six years. Evidence of beginning pulmonary tuberculosis, but no heart lesion was present. Had both grand mal and petit mal seizures.

October 4, 1906.—Following serial attacks this patient developed an acute pulmonary Œdema. Loud moist râles were heard over entire chest, and mouth filled with frothy mucus. Pulse was full and strong and respiration noisy. Examination of heart unsatisfactory, owing to noisy breathing, but there was apparently a murmur accompanying second sound at apex.

October 5, 1906.—Condition became worse; seizures recurred until death occurred at 1:45 p. m. Temperature was not above 100.8° F. No autopsy permitted.

CASE III.—Lillian S., age, twenty-six years. Onset of epilepsy at thirteen years. Both grand mal and petit mal. Patient well nourished. No heart lesion and kidneys normal.

June 9, 1906.—This evening patient had one grand mal seizure, following which she had a very marked pulmonary oedema. Profuse blood tinged frothy expectoration. Patient received atropine gr. 1/50, strychnine gr. 1/30 hypodermatically, and was dry cupped over chest. Temperature 100° F., pulse 120, respiration 68. Foot of bed was raised. Condition improved rapidly, and patient was in usual condition in thirty-six hours.

CASE IV.—Chas. W. J.; admitted to the Craig Colony on March 1, 1901; age, nine years. Seizures grand mal in type. No heart lesion when admitted.

September 10, 1906.—Following serial attacks he had marked pulmonary oedema. Entire chest was dull on percussion, and coarse, moist râles were present in large numbers. Given atropine and whiskey hypodermatically, and mustard paste applied to chest. Temperature 105° F., pulse 150, respiration 60. Temperature lowered to 103° F. by alcohol sponge. Three hours later temperature was 105.4° F., pulse 140, and barely perceptible at wrist. Oedema slightly cleared up. Frequent seizures continued. Patient rapidly became weaker, and death occurred six hours later. Autopsy, by Dr. J. F. Munson, showed brain very moist, and on section surface moist and somewhat foamy. Small amount of fluid in each pleural cavity. Heart weighed 165 grammes. Left ventricle firmly contracted. Muscle felt firm and good. Mitral valve admitted forefinger. Mixed clot under mitral valve flapped and extended up into auricle, making a cast of their cavities. Valve edges were thickened, but not hardened. Pulmonary artery admitted thumb with difficulty. Flaps were normal. Thymus persistent.

CASE V.—H. M. C., female; admitted July 1, 1902; type, grand mal and petit mal. Onset in early childhood. Note on admission read first sound of heart was not clear.

January 31, 1906.—This patient had some severe seizures early today, and soon developed a pulmonary oedema. Temperature (rectal) at 7 a. m. 101° F., pulse 100, respiration 20. At 10 a. m. she was dry cupped on back along both sides of vertebral column, and was given atropine gr. 1/100 every three hours. Large and small mucous râles could be heard over entire chest, but especially posteriorly over left lung. Palpation readily showed fluid in air passages. Because of large amount of adipose tissue, percussion was unsatisfactory. Heart sounds were rather indistinct, but appeared normal; pulse was of fair volume. Patient was partially conscious in interval between seizures and took some milk by mouth. Pupils were even and not dilated. No evidence of paralysis. Breathing stertorous. At 2 p. m. temperature 99° F., pulse, 120, respiration 40. At 2:45 p. m., grand mal seizure. At 4 p. m., râles seemed more numerous. She had another severe seizure at 5:35 p. m., and was much worse thereafter. Heart sounds were quite good at 7 p. m., as was also pulse; temperature (rectal), 101.5° F., pulse 132, respiration 40. Condition grew worse, and death occurred at 8 p. m. Considerable cyanosis and laryngeal râles were present for some time before death. Autopsy was not permitted.

CASE VI.—B. M. J., female; admitted December 18, 1902; age, eleven years; type of seizures, grand mal. Onset at three and one half years. Second sound accentuated. Urine normal.

January 18, 1906.—At 5:45 p. m. yesterday this patient began having severe seizures in rapid succession; she had just finished her supper and had appeared as usual. At 6 p. m. rectal temperature was 99.4° F., pulse 118, respiration 34. Patient was unconscious, and facial muscles were in clonic convulsions, with no interval free from convulsions. High cleansing enema ordered to be followed by enema of chloral hydrate, grs. xx, and potassium bromide, grs. xxx. Seizures were so severe that after the fourteenth the physician administered chloroform by inhalation until seizures stopped. There were marked stertor and increase of mucus in upper respiratory passages. After seizures stopped the mucus was so profuse that it poured through nose, patient became markedly cyanotic and respiration irregular and shallow. She was turned on her side and her head allowed to hang over the edge of the bed with her face down. Her mouth was pried open with a spoon and held so with the handle of a tablespoon; then the tongue was grasped with a towel and pulled out far enough to permit air to pass through larynx. Mucus was expelled from nose and mouth. Her condition began to improve, and she began to return to conscious ness. Pulse continued of good volume throughout.

At 7 p. m. rectal temperature was 98.6° F., pulse 120. At 10 p. m. she was restless, tossing about bed. With this exception she appeared to be in her usual condition. The following morning she was up to breakfast and about as usual.

April 1, 1906.—No prostration followed another series of seizures shortly after the one described. Physical condition was good.

July 31, 1907.—The patient had eleven grand mal seizures between 7 a. m. and 8:35 p. m. The last seven occurred in rapid succession between 8 p. m. and 8:35 p. m. Given chloral hydrate, grs. xx; potassium bromide, grs. xxx, by enema. Foot of bed elevated six inches. 9 a. m. atropine sulphate gr. 1/50 hypodermatically. Mustard paste applied to chest for twenty minutes. Following the last seizure patient developed a slight pulmonary oedema. Examination of chest showed slight impairment of resonance over entire pulmonary area. Rhonchal fremitus over same area. Scattered large moist râles over both lungs, but most numerous over upper and middle lobes of left lung anteriorly. Pupils were dilated. Patellar reflexes were very slight. The remaining reflexes were unobtainable. Patient was unconscious and slightly cyanotic. Pulse at 11 p. m. 100, regular and full; temperature 100°, respiration 24. Normal saline solution, 1 pint, given by rectum and repeated every three hours until patient returned to usual condition.

August 1, 1907.—Patient was bright and wished to get up. Examination of chest was negative, except a few scattered moist râles over left middle lobe anteriorly and in left axilla. 8 a. m. temperature 100°, pulse 86, respiration 20.

August 2, 1907.—Examination of lungs was negative and patient appeared in her usual condition.

CASE VII.—C. P., male; age on admission, April 4, 1903, was twenty-four years. Onset at eight years; grand mal and petit mal. Patient was well nourished, and heart and kidneys were normal.

November 14, 1905.—This patient had had quite frequent seizures for past few days, having had thirteen in three days, and this morning he had eleven. He was mentally disturbed since the day before, was constantly muttering to himself, and frequently cried out. His temperature was 102°. He was transferred to the hospital. Examination showed both lungs filled with loud moist râles, and some dullness was noted over left lung in front. Tongue was coated with heavy brownish fur. There was some congestion of face and neck, which increased during the evening. Respirations were labored and noisy, abdominal muscles being brought into use. Mouth was filled with a thick viscid mucus which had to be cleansed quite often.

November 15, 1905.—He was disturbed during early part of night, but after 10 p. m. was quiet. Temperature rose last evening to 102° F., but this morning was 100° F. Free perspiration last night, and patient could not be aroused. Saline infusion into both mammary regions this morning. Pulse was rapid and feeble, the respirations being less frequent and more shallow, and patient died at 10:50 a. m.

CASE VIII.—I. M. B., admitted June 21, 1905; age, sixteen years; onset at six years; heart and kidneys were normal.

October 1, 1905.—This patient had four mild seizures yesterday and complained of pain in her abdomen. At about 4:45 p. m. she passed into a condition of status epilepticus, seizures beginning by head being turned to right. When seen by physician she was having a general clonic convulsion, was markedly cyanosed, breathing, stertorous, with an unusual amount of mucus in the upper respiratory passages; bathed in a profuse perspiration, pupils small and no reaction to light, corneal reflex absent, reflexes absent in extremities, pulse 160; rectal temperature at that time was 102.0° F. This morning she was in her usual condition. After convulsion she had a slight lateral sweating. Right pupil was considerably larger than left, but both responded quickly to light.

March 12, 1906.—At about 10 a. m. yesterday, night nurse found this patient in a condition as if she had had a severe seizure. Patients in same room said she had convulsed for half an hour. She was lying in a comatose position, with considerable mucus in upper respiratory tract. Pupils were moderately dilated. Pulse 150 per minute, but of good volume; rectal temperature 101° F.

Patient semiconscious and very restless. Knee jerks, wrist jerks, and elbow jerks were active; no ankle clonus; Babinski reflex present on both sides. At 11 p. m. temperature had dropped over two degrees. At 7 a. m. temperature 100.4° F. Tongue lacerated. Patient was pale, but otherwise in about her usual condition. Later in the year she had a similar condition develop following seizures. Recovery.

CASE IX.—E. F., female; admitted March 24, 1904; age, seventeen years. Grand mal. Onset at one year. Accompanied by second pulmonic sound. Urine normal.

May 5, 1905.—This patient had a grand mal seizure last evening. After the attack she developed a moderate hemoptysis which gradually became less marked. Ice was applied over her chest and she was given fragments of ice to place in her mouth. Morphine, gr.  $\frac{1}{4}$ , and atropine, gr.  $\frac{1}{150}$ , were given hypodermatically. Pulse was 120. This morning she was quite comfortable. Temperature 98.8° F., pulse 112, respiration 35. She had very large tonsils and probably adenoid in nasopharynx. This morning an examination of the chest revealed many coarse râles over right lung, especially along border of ensiform appendix.

CASE X.—J. K., male; admitted March 28, 1905; age, eleven years. Lungs normal. Status with pulmonary oedema every six to eight weeks. Occasional isolated grand mal seizures.

August 3, 1906.—Temperature 103° F. Seizures stopped on administration of chloroform, morphine, and atropine. Oedema cleared up in twenty-four hours.

November 25, 1906.—Status controlled by chloroform. Pulmonary oedema and marked bronchorrhoea, with quantities of mucus from mouth and nose. Under treatment cleared up in twenty-four hours.

CASE XI.—C. H., female; admitted April 30, 1896; age, twenty-one years. Grand mal. Onset at fourteen years. No heart lesion.

March 7, 1905.—This patient had several severe seizures last night and some today. This morning she was comatose and remained so all day. In the afternoon she had a slight elevation of temperature; pulse became very rapid, as did also respiration. Breathing was noisy, and laryngeal râles were present. Auscultation showed many râles in both lungs as a beginning of oedema of lungs. She was given atropine sulphate, gr.  $\frac{1}{60}$ , and strychnine sulphate, gr.  $\frac{1}{20}$ , hypodermatically. Latter drug repeated at intervals of two hours for three doses, then gr.  $\frac{1}{40}$  given every two hours.

March 8, 1905.—Condition was improved. Very few râles heard over either lung. Patient coughed occasionally, but did not expectorate. She took nourishment by mouth, and was much brighter mentally. She did not answer when spoken to. When smiling, muscles of right side of face contracted more than did those of left side. She had a few mild seizures, which consisted of head being turned to left; slight lateral nystagmus and chewing movements; no automatism or stertor; duration about five seconds.

March 10, 1905.—Patient has much improved, but did not talk. She took nourishment easily. Lungs were free from râles. Still some elevation of temperature.

August 10, 1907.—Patient had serial attacks yesterday morning at 5:30. In spite of the administration of chloral and bromide in large doses, and thorough flushing of the bowels, the seizures continued, and pulmonary oedema supervened. In the past twenty-four hours the patient had had forty-one seizures, and was in the morning at 8:00 in a critical condition; temperature 100.6°, pulse 152, respiration 48. The oedema of the lungs was increased in severity and the seizures recurred about every half hour. Nitroglycerin, gr.  $\frac{1}{100}$ , administered at 8:45 a. m.; copious enemata of warm water, dry cups. Since last note her condition had become progressively worse. She had ten severe attacks between 5:30 a. m. and 12:55 p. m., and died at 1:05 p. m.

Autopsy: August 11, 1907.—Froth about nostrils. Hypostasis fairly well marked and patchy in character present on upper chest and neck. Brain, large and soft, very moist, and congestion marked. Microscopical examination was negative. Both lungs showed moderate congestion and oedema. Heart weighed 230 grammes; there was large chicken fat clot in pulmonary artery; right heart contained mixed clot. Examination of valve was negative; endocardium was pale.

### CONCERNING THE FIRST WEEK OF INFANT LIFE.\*

By DE WITT H. SHERMAN, M. D.,  
Buffalo, N. Y.

The period of life which I have selected to discuss is one of much more importance than is usually considered, and really presents a subject too broad to be covered in its many manifestations in one paper.

The object of the paper is to recall to the mind of the busy practitioner some of the often neglected precautions which can be taken in behalf of the infant and to impress the necessity of asepsis in their management. As a class of patients, I do not suppose there is another one which is handled with so much carelessness, almost neglect, as the newborn babe. If it cries after birth, and starts to functionate, the physician, as a rule, seems to think his duties toward the child are finished, and it is turned over to the nurse or attendant without definite instructions as to its care, or any warnings as to the dangers which beset it. In its early hours or days we have appreciated that disturbance of the equilibrium of its vitality is to be feared, and we are beginning to appreciate more and more the dangers of specific morbid processes to which it is very susceptible.

Only by reviewing the statistics of infant mortality during the first month of life, and studying the causes of the high death rate, can we fully appreciate the responsibility imposed upon us in their care. Eröss gives the statistics of sixteen large cities of Europe, which showed 1,439,000 births, with a mortality during the first four weeks of life of 9.5 per cent., which means 130,610 deaths. If the vitality is measured by the weight, it is considered that  $6\frac{1}{2}$  pounds shows a fair vitality,  $5\frac{1}{2}$  pounds low, and  $4\frac{1}{2}$  pounds very low. To safeguard those of low vitality there are a few subjects worthy of consideration, and one of the most important is that of the body temperature, for it gives definite information of the child's ability to endure its new surroundings. In the small or sickly infants, then, the temperature should be taken every six to eight hours, for their heat radiating surface being relatively more active, as well as greater, than the adult, they easily become markedly depressed from chilling. Refrigeration produces a shock which is momentous to the newly born.

During the first day or two of life is the only time the surface temperature may be considered an accurate indicator of the actual temperature of the infant. Then, and then only, is the surface temperature at all justifiable; but even then the rectal temperature is more reliable, and should be the only one considered by the careful observer.

A. H. Parks, of Chicago, asserts that the groin

\*Read at a meeting of the Buffalo Academy of Medicine, November 12, 1908.

temperature in the normal infant varies only  $\frac{1}{2}$  degree F. from that of the rectum, and for æsthetic and other purposes is to be preferred. I cannot elevate myself to this high plane of æstheticism even in the female infant, and know of no other poorer or yet better reason than æstheticism for taking an infant's surface temperature. If the skin is thoroughly dried, and the one half minute thermometer is left in situ for from three to eight minutes, this slight variation of  $\frac{1}{2}$  degree F. may be true in the normal infant, but in the pathological states one sees the surface temperature often about normal with a rectal temperature that is very high. I consequently urge that the surface temperature be always considered misleading. The temperature per rectum should be kept above 98° F. The birth temperature is about 99 $\frac{1}{2}$ ° F., and in one hour is apt to be 96° or 97° F., and not for a week can the child easily maintain 98° F. or over.

A second fruitful cause of physical depression which may prove fatal is the disregard of the amount of food ingested by the very young. It is put to the breast, draws as strongly as its weak muscles will allow, and from fatigue falls asleep apparently satisfied, but in reality only having gotten a teaspoonful or two of nourishment. Soon it awakens, cries, and is again put to the breast for another almost dry draw, and takes another cat nap. Bad habits are formed, castor oil is given for supposed colic, and the infant is correspondingly more depressed and weakened, and the case becomes more complex. As a remedy all that is needed is a pair of scales to learn the amount of food the babe is getting, and to supply this want, if it is not being sufficiently fed. The stomach of the newborn holds 25 c.c., almost an ounce, and, like most human beings, it enjoys having it filled occasionally, especially after a day or two of almost complete fasting.

A third physical cause of depression is pain arising from the fact that too little water is given to the newborn, and too often is there a neglect to add to this water a small amount of an alkali. It is commonly known, and almost as commonly forgotten, that uric acid infarction of the kidney of the newborn is not infrequent. Post mortem examinations show the orange or light red color near the pyramids, usually due to the ammonium urate, amorphous urates, or uric acid crystals. They are easily washed away by water, especially if it contains an alkali, and this simple remedy promptly produces relief of pain, too commonly treated by castor oil given in doses for the newborn heroic. As a routine practice I give all my infants a little weak sodium bicarbonate water during the first couple of days of life.

As a fourth cause of physical depression some criticism is justifiable of the rougher methods of performing artificial respiration. Because many an infant can survive low body temperature and lack of food, so can many stand the rough handling of some of the methods, such as the swinging ones. But for the weak these methods are very exhausting, and in any case should be omitted, if possible.

A simple, not heroic, and very successful method, called Byrd's method, is to allow the infant to lie with its back on the palm of one's hand, with two

fingers supporting its head. The thumb encircles one side of the chest, and the fourth and little finger the other. The other hand grasps the legs. As the thighs are bent onto the abdomen, compressing it, the chest can also be compressed. As the thighs are extended and the body arched backward, the chest can be released. It can be performed in a warm bath, if advisable, and accomplishes good results with a minimum of fatigue. It compresses the chest, and by its rhythmical pressure massages the heart.

In the severe cases the violent methods may be necessary. In these where the reflexes are wanting it seems to me there is little avail—in fact, time is wasted—in resorting to Laborde's tongue traction method, which is supposed to irritate the superior laryngeal, the glossopharyngeal and the lingual nerves.

Sheili, of Dublin, recommends injecting a small amount of adrenalin through a silver cannula, inserted into the umbilical stump, the ligature having been loosened, to relieve shock and to assist the various methods of artificial respiration. It is so much of an operation that it is rarely feasible. The simpler and gentler the procedure of artificial respiration necessary to produce the desired results the better. In many of the conditions, such as malformations, injuries during labor, etc., we may be powerless to accomplish more in saving life than we are now accomplishing, but in many of the conditions, nervous, pulmonary, gastrointestinal, and the like, which are of a possible infectious nature, we may, by strenuous efforts, produce better results than we are now securing.

Many conditions previously thought functional disturbances are now considered infectious. To just what pathogenic bacteria some of them are due is not now known, for, as the result of a great deal of research, there is no single germ or series of germs always present in a given set of symptoms.

If the mortality from septicæmia can be so greatly reduced by strict asepsis, as has been done, especially in maternity hospitals, so can we, in both institutions and in private practice, help decrease the infant mortality by similar properly directed care.

In considering the sources of infection of the newly born we may start with the placenta, which has been proved to be a fairly reliable filter to prevent infection of the fœtus in utero, although the protection may not be complete. We have the transmission through it of syphilis, and it may be of tuberculosis, and some other infections, as well as the toxines of various diseases. This is a source we cannot well control, but the vagina, which we know often teems with bacteria, does come within our scope, and I see no reason why more attention cannot be paid, opportunity and time permitting, to cleanse and disinfect it. With the vagina fairly sterile we come next to the hands of the attendants, the careless use of which are undoubtedly the cause of very many of the conditions, properly considered infectious, those gastrointestinal and pulmonary included. Could the responsibility be definitely placed, the relief would be promptly afforded. The accoucher with hands contaminated from careless cleansing or from the fecal matter expelled from the bulging anus, or the nurse who cleanses the anus

for him or handles other infected articles, either one may jeopardize the child's life by introducing some pathogenic germ on the finger inserted into the child's mouth to remove the mucus or liquor amnii. Consequently let the mouth alone, whenever possible, or see to it by previous instructions that the nurse with sterile hands and a finger incased in sterile soft gauze be the only one to attend to this part.

In institutions the opportunity for dissemination of disease germs is recognized and vigorously met, but in private practice too little attention is paid to strict asepsis in the care of the infant. How many trained nurses are there who are told, after cleaning the lying-in bed, to sterilize their hands before washing out the newborn infant's mouth in its first toilet? They appreciate the necessity for asepsis in the care of the nipples to prevent inflammation or abscess of the mammary glands of the mother, but will show the physician a soiled diaper and soon prepare the nursing bottle with food or drinking water.

During the first three of four days the infant needs water to drink more than most any other time in its life. If sterile water with soda is given for the first twenty-four or thirty-six hours, plain sterile water can later be used, which may, with comparative safety, be allowed to remain in the drinking bottle on the radiator for immediate use. But think of the bacteria growth we may be administering if the plain or even filtered Niagara River water be left comfortably warm for an indefinite number of hours for this same immediate use. Undoubtedly many an infant has been made seriously ill by this one procedure.

In considering the port of entrance of infection it is often difficult to determine it definitely, but the mouth, according to Hamill, is probably the commonest gateway, the cord, lungs, and other avenues and parts of the body following in about the order mentioned.

Let us consider briefly some of the symptoms of infection often supposed to be other conditions. The first are the gastrointestinal disturbances. When pathogenic germs are inserted by mouth the common set of symptoms are those of intestinal indigestion or colitis. The child is not anxious for food, cries from pain, has loose undigested stools, generally containing mucus, and has fever. These symptoms appear anywhere from the third or fourth day to the fourteenth or eighteenth, and should, in the large majority of cases, be considered an infection rather than an indigestion from improper percentages of food strength. The breast milk, which may contain the source of the trouble, or the artificial food should be stopped for a few hours or a day, and the gastrointestinal canal cleansed with sterile water, calomel, or small doses of oil. Soon other good breast milk or different artificial food should be used, and used sufficiently long till the mother's breasts or milk seem normal, or the return to modified milk seems perfectly safe. By treating these conditions as *infectious* rather than indigestions, our measures will be more prompt, more thorough, more supportive, and more definitely directed to the point, thereby checking the disease in its incipency.

Another class of conditions for which we do not seem to hold ourselves responsible are the pulmonary

infections. We fairly often hear of inspiration pneumonia of the newborn. The diagnosis may be made from the rapid irregular respiration, cyanosis, high fever, and prostration rather than from definite physical signs. In these cases the autopsy reveals absolutely no pulmonary lesion, showing only that the condition is an infection through the respiratory tract, or brought to it from some focal point.

We can in the same manner account for other involvements, such as the skin with its numerous eruptions of varied types, the erythema, the ecchymoses, erysipeloid eruptions, and the petechiæ; or of the nervous system, such as muscular twitchings, rolling of the eyes, retraction of the head or convulsions, symptoms which cannot be accounted for by trauma or hæmorrhage, or pressure inside or outside the skull cap.

These nervous symptoms may be laid at the door of the kidneys, but can we say that the kidney involvement is primary and not secondary to some systemic infection? The kidneys of the newborn are easily vulnerable and may contribute. According to J. Lovett Morse, the presence of a small amount of nuclealbumin in the urine during the first four days of infant life is constant, and lasts often for two weeks. This albumin he considers due to the changes in circulation, to hyperæmia resulting in excessive metabolism after birth, to renal disease in the mother, and to uric acid irritation. While there is evidence that uræmia may sometimes be the causal factor, there is just as much evidence that the kidney involvement is a complication of the general infection. The treatment then includes the removal of the focal point of infection, as well as overcoming the symptoms of the nervous condition.

Gallant, in a thorough article on the umbilicus in the newly born, quotes Cholmogoroff, who demonstrated that the cord at birth is free from microorganisms. He differs from Hamill, and considers that umbilical infections are more common than by mouth, and refers to 1,000 infants, studied by Eross, in whom but thirty-two per cent. ran an afebrile course. Eross concludes that the greatest danger of infection is through shrapnel of the cord. The commonest microorganisms causing infection are the *Staphylococcus aureus* and *Streptococcus pyogenes*, and they are probably the exciting cause of four fifths of the cases, the staphylococcus producing, as a rule, the milder symptoms. Infection of the navel from the clinical aspect depends first upon the extent of the involvement, whether limited to the cellular tissue, arteries, or the vein, or commencing in one and extending to the others, and, second, the virulence of the microorganism. When the base of the stump is infected, the sloughing tissue, moisture, and warmth give favorable soil for their multiplication. The toxins eliminated by them are absorbed, causing toxæmia, with fever and symptoms pointing to some particularly affected part. Through the short thrombosis of the arteries or vein, which is only an inch or so in length, the infection reaches the other parts of the body, early attacking the liver and producing jaundice, or carried to the lung producing pneumonia, or if to the brain purulent encephalitis or cerebral abscess.

The icterus neonatorum is probably more often hepatogenous than hæmatogenous, especially if asso-

ciated with a mild fever, and occurring on the third to the fifth day. The point of danger is the attacked base of the cord, and the period of danger ends not with the separation of the cord, but with the cicatrizing of the granulation surface beneath it. The best dressing then is a dry, sterile gauze or linen without drying powder, so applied, if possible, as to prevent air contamination, and taking pains in applying new dressings not to touch, wipe, or handle the base. Gallant recommends balsam of Peru 1 part to 16 parts of castor oil, both sterile, applied to the base with a thick occlusive dressing of sterile gauze for the cord, the whole held to the abdomen by adhesive straps. It is to be changed when soiled, or every third or fourth day, and by the physician, and only under aseptic precautions.

A recent fatal case of malena neonatorum has impressed me with the virulence of the cause, if it is an infection, and also brought prominently into my consideration the possible effect, as a causal factor, of maternal intoxication upon the fœtus. Let me briefly relate the case:

This young woman had borne previously two healthy girls, and was in perfect condition, except for rather unusual periodical headaches, occurring about the time of menstruation. A healthy eight or nine pound boy was born after a short labor of four hours, during which only one vaginal examination was made. Immediately after birth a large amount of liquor amnii ran from the child's nose, and it ejected from its mouth a large mass of mucus. Its mouth was gently wiped out with sterile gauze by the nurse, whose hands had been carefully cleaned numerous times. The cord, which was thick, was thoroughly tied after stripping, but in an hour commenced to bleed. During the first day it was tied eight times, all promptly successful, but later ineffectual. When nine hours old the baby vomited a little rather bright red blood, and as the case was suspected as possibly being one of malena neonatorum, treatment was commenced at once. Careful physical examination of the infant at this time revealed nothing abnormal. As time advanced the cord continued to ooze, more blood was vomited, there were bloody stools, and petechial hæmorrhages appeared on the left thigh, and later on other parts of the body. Frequently the child seemed in great distress, cried out, presenting a typical facies of pain. Its temperature was never above normal, rather an unusual condition for ordinary infections, and its pulse and respiration were not much altered. In spite of energetic treatment, the child died when forty-four hours old, literally having bled to death.

The treatment of the cord consisted, besides frequent ligation, of pressure, applications of adrenalin, Monsel's solution, and the actual cautery, all without avail. The internal bleeding was treated by means of a 4 per cent. gelatin solution given by mouth in teaspoonful doses, also calcium chloride in gr.  $\frac{1}{2}$  doses, soon followed by ergot hypodermatically and normal saline hypodermochysis. As a supportive measure I fed the child on diluted, later whole, breast milk. The blood from the cord, stomach, and bowels was taken in sterile tubes and cloths and examined by Dr. C. A. Bentz. He reports finding the *Streptococcus pyogenes*, *Staphylococcus aureus*, and the *Bacillus coli communis*. There were no other growths on his cultures. A post-mortem examination was refused and hence further samples of blood were not obtainable.

Hamill, in discussing this subject, mentions six different microorganisms isolated, viz., *Bacillus pyocyaneus*, *Bacillus lactis aerogenes*, *Edin. bacillus*, *Staphylococcus aureus*, *Bacillus coli immobilis*, and the *Streptococcus pyogenes*. These are the ones most commonly found. He also mentions, as found by others, the pneumococcus, Pfeiffer's bacillus, the bacillus of Babes, *Bacillus hæmorrhagicus* or Kolb, bacillus of Gaertner, and the encapsulated bacillus

of Dugern. Of all these the streptococcus, the *Bacillus coli communis*, and the staphylococcus are most commonly encountered.

Almost all writers on this subject consider the condition due to infection, but there are others who lay stress upon maternal intoxication. In my case the symptoms were more those of shock from hæmorrhage than from infection, and the structural or anatomical defects possible from maternal intoxication are worthy of consideration. During the last two weeks of her pregnancy the mother experienced two or three headaches, and some pain along the course of the spinal column. Albumin appeared in the urine, and the kidneys functionated a little less actively, though on the whole they behaved fairly well. These probable uræmic symptoms were not severe enough to be alarming, and were expected to be only of short duration, since the date of the accouchement was only a few days off.

The factors we have in this case are maternal intoxication, probably of kidney origin, an apparently healthy infant born in a room thoroughly house cleaned, attended by persons carefully cleaned. The infant died of numerous free hæmorrhages shortly after birth, and at no time had had a rectal temperature over 99.5° F. It is a history and set of symptoms which may point to an infection, but also is very suggestive of a lack of coagulability of the blood or impaired ability of the bloodvessel walls to retain the blood, one or both possible conditions following maternal intoxication.

Malena neonatorum is supposedly a self-limited disease, commencing in almost all cases within the first ten days, in many cases on the second day, and lasting for five to nine days. As a rule, the amount of blood is not excessive, but is none the less a dangerous condition because the bleeding is continuous. Townsend, of Boston, found reports of 709 cases having a mortality of seventy-nine per cent. The intestinal hæmorrhages generally begin early, within the first three days, the umbilical hæmorrhages more commonly coming later, from the fourth to the seventh day. If the bleeding is from the female vulva and occurs alone it is generally not dangerous. Hæmorrhage in the newborn does not appear to have much relation to hæmophilia. McClanahan, of Omaha, in looking up this subject, mentions Grandidier's statistics of 576 hæmophilics, and only twelve of them had any history of early bleeding.

Edward P. Davis made a valuable contribution in reference to prenatal infection in diseases of infancy by examining the blood of twenty-six mothers and infants, and reached the following conclusions, viz.:

The infant's blood is not dependent upon the mother's plethora or anaemia for its cells or hæmoglobin; except in acute infections the placenta is usually sterile; the fœces of the infant before it has nursed may contain micrococci; the mother's milk before the infant has nursed may contain micrococci. In conditions of maternal toxæmia the same poison which affects the mother is transmitted to the child, in some instances by substances other than bacteria. There exists in infants a toxæmia of intestinal origin, mild cases of which are susceptible to treatment, while severe cases end in multiple hæmorrhage and death. In the latter a germ, resembling that asso-

ated with yellow fever, is capable of transmission through pregnant animals to their young and has been isolated.

So far as treatment is concerned, thorough lavage of the intestines with sterile saline solutions gives best promise of success. Should the mother's milk be infected, sterile modified milk or other foods known to be sterile should be employed.

680 WEST FERRY STREET.

## ON THE ABORTIVE TREATMENT OF GONORRHOEA IN THE FEMALE.\*

By FREDERIC BIERHOFF, M. D.,  
New York,

Attending Physician, Dermatological Department, German Dispensary; Member of the Academy of Medicine; Corresponding Member of l'Association française d'urologie, etc.

By the term "abortive," in relation to treatment, we mean that form of treatment which brings about a cure of the disease upon one or two applications. The term is used in contradistinction to the prophylactic, or preventive, methods, which do not come under the scope of this paper. While the latter methods seek to prevent the *development* of a gonorrhoea in a person who has been exposed to the possibility of an infection, the abortive method seeks to cure an already present gonorrhoea.

In order to be able to abort a gonorrhoea in a female, the disease must be recognized in its very earliest stages, and before any structure other than the urethra itself, or the urethra and vulva, or vagina, has become involved. In the early recognition of this disease we find our greatest difficulty to the successful accomplishment of an abortive treatment, for women very rarely present themselves to the physician for examination to determine the presence of a gonorrhoea.

This disease frequently runs so mild a course, the infection is of so mild a type, that the women usually ascribe the very slight symptoms which they notice to a possible urethral irritation or a slight "cold," rather than to the possibility of gonorrhoeal infection. When a woman, whose suspicion of gonorrhoeal infection has been aroused, presents herself to the physician for examination as to the presence or absence of gonorrhoea, the physician, in by far the large majority of cases, contents himself with a physical examination of the parts, and, should he not find distinct evidence of an acute inflammatory process, which he recognizes by a reddening of the vulva and meatus, and by the presence of a more or less purulent discharge, pronounces the woman to be free from infection.

Were physicians to rely *solely* upon the outcome of a microscopical examination of the scrapings from the urethral and cervical canal, they would find that a fair proportion of supposedly healthy women are, in reality, afflicted with gonorrhoea in a subacute or chronic form. Since I have based my diagnoses solely upon the microscopical findings in the cases of females, I have been surprised to find how many of them there will be found who, in the absence of any inflammatory reaction about the urethral orifice,

or in the absence of any visible discharge whatever, are still found to be infected with gonorrhoea, as shown by the presence of typical gonococci in the urethral and cervical scrapings. Were the initial stage of a gonorrhoea in a female accompanied by more severe symptoms—that is, more pronounced distress upon urination, as is the case in the male, so that the women were led to consult a physician early in the disease—and were physicians to rely for their diagnosis solely upon the findings under the microscope, I feel sure that a large percentage of the women examined would be found to be suffering with gonorrhoea, and an abortive treatment might be possible in a larger proportion of the cases found infected. Unfortunately, however, in almost all of the cases of gonorrhoea in females, the patient presents herself at a time when the process has already gotten a deeper foothold in the urethra, or when the urethral crypts, or the cervix uteri, have become infected. Then, of course, an abortive cure is impossible.

Frequently, too, it is difficult to decide whether the urethritis is in the early stage of an acute infection, or whether it is of a chronic character. In the decision of this point, I have found the following facts to be of great value to me. In acute urethritis the condition will be found such as Bumm has so beautifully described in his report upon gonorrhoea in the female, as a result of his inoculations with pure cultures of the gonococcus: "After the inoculations a serous, transparent, yellowish secretion appears, which contains but few pus cells, but myriads of epithelial cells. In these, and between them, the gonococci lie in large numbers, in colonies, and solitary examples." Similarly, in the female as in the male, Bumm's experiments have shown that these clinical signs occur about the third day after inoculation. Later on, during the first weeks, the proportion of pus corpuscles increases.

In chronic cases of urethritis in the female, I have found, in all instances, that we have to deal with more or less faint traces of mucopurulent secretion, which is found, upon examination, to consist of broken down pus corpuscles, epithelial cells, and mucus. The microscopic organisms are chiefly bacteria other than the gonococcus, and usually occur in the form of bacilli and diplobacilli. The gonococci are relatively few in numbers, but, upon careful examination of the specimen, points will be found where they have the typical form, and intracellular location. In the acute stage of the infection the gonococci are numerous, and many lie in the pus cells; the pus corpuscles will be found to be fresh in their appearance, and to retain their cell contours and their nuclear contours much more perfectly than in the chronic stage of the disease, where the cell bodies will be found to be broken and degenerated, and the nuclei very often riddled with vacuoles.

It will be seen from these observations that, in order to effect a cure by the abortive treatment, it is an *absolute necessity* to make the diagnosis early, and that, in order to do this, one must possess the requisite degree of bacteriological knowledge to determine the exact character of the condition to be treated. I have found that, in making the microscopical examination, the ordinary watery solution of methylen blue, or the alkaline methylen blue, is fully sufficient

\*Read, in abstract, before the New York County Medical Society, March 25, 1909.

to enable us to make a clinical diagnosis, where the question is one of distinction between the gonococci and other diplococci; but in the chronic stages it may become necessary to resort to the Gram distinctive stain, and where the question becomes one of medicolegal importance, the culture experiment must be resorted to.

The condition, *sine qua non*, then, of the abortive treatment of gonorrhoea in the female is, just as in the male, the microscopical examination. If, now, the patient presents herself at an early stage of the disease, and if it be found upon examination that the gonorrhoeal infection has not extended to the Bartholinian glands, or to the cervix uteri, then the attempt to employ the abortive method is justified, for, if we do not achieve an abortive result, we do not injure the patient, nor do we do anything that would favor the spread of the infection. Where the Bartholinian glands or the cervix uteri are involved, an abortive treatment is impossible.

That the urethra is, in a large proportion of the cases, the seat of gonorrhoea in the female, has been determined by careful examinations of competent observers, and this is in direct contradiction of the views which were formerly held. Steinschneider found the urethra involved in forty-seven per cent. of the cases; Horand, however, in seventy-five per cent., and Baum, Luczny, and Wolff in ninety per cent. The findings of other observers agree, in the main, with these statements—that, in by far the large majority of all cases of gonorrhoea in the female, the urethra will be found to be involved. Where the conditions for the employment of the abortive treatment are favorable (and I frankly admit that this is, owing to the circumstances which I have named, in but a small percentage of the cases of gonorrhoea coming to our notice), the procedures which I have employed with success are as follows:

I. A microscopical examination of the urethral secretion, or scraping, and of the secretion showing at the vulvar orifice.

II. Cleansing of the meatus, and irrigations of the urethra and surroundings with a solution of one quarter to one half per cent. solution of protargol. Either the hand syringe or the irrigator may be employed, but no great degree of pressure should be employed. In all about 150 c.c. are used for the urethra and surroundings, after which about 150 c.c. of the fluid are injected, through the urethra, into the bladder, to be later expelled by the patient. In this latter irrigation, the patient is instructed to relax the muscles, as though about to urinate, when the urethra feels distended, whereupon the fluid will be found to flow easily into the bladder.

III. Cleansing of the vulva with 150 c.c. of the solution.

IV. A vaginal scraping is now made and examined, the sterilized platinum loop being passed well into the vagina for this purpose.

V. The nozzle of the syringe is gently inserted into the vagina, the stream of the solution, during this time, passing into the vagina, and the nozzle inserted up to the point where the body of the syringe blocks the outlet. The syringe blocking the outlet to prevent the escape of the injected fluid, the injection is continued until the vagina becomes distended with this solution, which is then allowed to flow out.

About 300 c.c. of the solution are used for this vaginal cleansing.

VI. A sterilized speculum is inserted into the vagina—preferably of the duckbill type—and the vagina, particularly the fornices and the cervical orifice, cleansed by gently wiping with little cotton pledgets.

VII. A specimen of the cervical secretion, or a scraping from the cervical canal, is now made with the sterilized loop, and a microscopical examination thereof made. Should this be found to be free of gonococci, and to contain few or no pus corpuscles whatever, then the vagina is lightly tamponed with several yards of narrow, absorbent gauze strips, saturated in one per cent. protargol solution, and the speculum withdrawn. I employ the tamponade whether the vagina be infected or not. If it be infected, I employ a five per cent. solution. There is then an exfoliation of the superficial epithelial layers, and usually, in from twenty-four to forty-eight hours, the vaginal secretion will be found to be sterile. If the vagina be not infected, its infection is prevented by this tamponade.

VIII. A soluble urethral bougie of five per cent. protargol in cacao butter, made of a length of an inch and a half, is inserted into the urethra and left therein.

IX. While the index finger of the left hand maintains the urethral bougie in place by pressure of the finger against the meatus, a pad of absorbent cotton, saturated with one per cent. protargol solution, is placed over the urethral and vulvar orifices and kept in place with a "T" binder. As the patient has urinated in emptying the bladder of the fluid injected into it, she is now instructed to resist the desire to urinate, if possible, for several hours, so that the drug in the melting bougie may be kept in contact with the urethral mucous membrane for as long a period as possible. The pad covering the vulva is also kept moist with the one per cent. protargol solution.

X. Rest in bed, if possible, is of advantage in the treatment. Bland diet should be ordered; all intoxicating or carbonated drinks avoided, and all highly spiced articles of food omitted from the dietary. A daily warm sitz bath, in the evening, completes the treatment. The tampon is left in place for twenty-four hours, whereupon it is removed by the physician, and the treatment, as outlined, repeated. Should the patient desire to urinate, the moist pad is simply removed, to be replaced at once thereafter. Under this treatment, within twenty-four to forty-eight hours, if the cure is to prove a success, the urethral secretion must be free of gonococci, as must also the vulvar and vaginal scrapings. After two such applications, if there be no more gonococci present, it is my custom to begin the tests by omitting entirely the urethral irrigation and bougie, and by substituting a vaginal irrigation of bichloride of mercury solution, 1 in 4,000, or a solution of one half per cent. zinc sulphocarbolate for the irrigation with protargol, and the vaginal tampon is entirely omitted. The warm sitz baths are, however, continued for a few days longer. Should the test of the interruption of treatment be followed by no return of gonococcus bearing secretion, then we proceed to the alcohol test. Further control examinations must be made at intervals, and only when the

urethral and cervical scrapings continue free of gonococci, even after the next following menstruation, may we discharge the patient as definitely cured. Should discharge with gonococci reappear during the tests, then we simply continue with the treatment until the patient is cured.

51-53 EAST FIFTY-EIGHTH STREET.

### CEREBRAL CONTUSION.\*

BY CHARLES S. WHITE, M. D.,  
Washington, D. C.,

Superintendent, Emergency Hospital.

An injury to the head sufficient to cause loss of consciousness for a brief period is the strict limitation of concussion, but the more prolonged coma or manifestation of cerebral incompetency without fracture should be defined as cerebral contusion. It is very probable that so called concussion is but a slight degree of contusion, but it simulates the latter condition in its aetiology, pathology, and symptomatology, and Kocher maintains that there is no place in a medical vocabulary for the word "concussion."

The causative agent is trauma, applied directly or indirectly. A blow upon the vault or striking of the head upon an unyielding substance are the more usual factors, but the force may be transmitted through the spine, as severe falls upon the buttocks may be followed by severe symptoms of cerebral contusion. If the object through which the force is applied is of a yielding nature, contusion of the brain is likely to be a sequence, but fracture is improbable, hence the use of sandbags and lead pipes as weapons of assault is founded upon a rational basis.

The pathological changes following cerebral contusion vary from those of microscopic proportions to tremendous hæmorrhages. In the milder types of the affection the changes are not evident to the eye perhaps, but section will show minute rents in the white and gray matter, with here and there a pinpoint hæmorrhage. This would correspond clinically to the degree of unconsciousness popularly called concussion. In the more severe cases, the variations in the pathology are of degree rather than character. The lacerations may be invisible, but punctate hæmorrhages may be seen throughout the brain, varying in size from a pinpoint to the size of the lead in a pencil. In those cases which result in death, the lacerations may be evident to the eye, and the hæmorrhage, either cerebral, subdural, or extradural, may be of great magnitude; therefore the term diffuse cerebral contusion has been appropriately applied to this condition. While in the majority of cases the lesion lies immediately beneath the point where the greatest force was focused, in many instances it is widespread and no part of the cerebrum escapes the violent oscillation. On the contrary, the lesion may be one of contrecoup, and especially is this true of hæmorrhage. In a personal communication the deputy coroner of the District of Columbia, Dr. L. W. Glazebrook, states that in 500 autopsies he found death the

result of cerebral concussion or contusion, without a gross lesion, in seven cases, and in twenty-four cases there was hæmorrhage without fracture.

With hæmorrhage of any intensity there is increase of the intracranial pressure, many instances severe enough to retard the venous outflow; in other words, a passive congestion. Following this is an exudate from the vessels, œdema of the brain, the pressure of which modifies, but does not paralyze, the medullary centres, but retards or prevents the normal cerebation, both psychic and physical. The centres in the medulla are vital and are the last to succumb to the increased tension. With the increased pressure an anæmia is the physiological result, inasmuch as the calibre of the cerebral vessels is reduced by compression. The higher centres in the medulla feel this loss of arterial blood, and from the reflex stimulation the heart attempts to force more blood into the brain; hence the full bounding pulse and increased blood pressure. The œdema may be temporary or more or less permanent. To quote Osler: "The symptoms of compression following concussion or contusion, as shown by Cannon, are frequently attributable to cerebral œdema due to changes in osmotic pressure. . . . The anatomical changes are not unlike those of anæmia. (When the anæmia follows progressive atrophy, the fluid is chiefly in and beneath the membranes.) The brain substance is anæmic and moist, and has a wet, glistening appearance which is very characteristic. In some instances the œdema is more intense and local, and the brain substance may look infiltrated with fluid."

The gray matter of the brain does not regenerate, once destroyed, and the lacerations which follow contusions of the brain are permanent gaps in the communication from cell to cell, bridged over by fibrous tissue derived from the lymphocytes or wandering cells of the blood stream. The co-ordination of ideas or acts may be seriously interrupted by the distribution of fibrous tissue. The reparative process may seriously interfere with the circulation and a permanent œdema of the brain be the consequence.

*Symptomatology.*—Following an agitation of the brain or violent movement from direct or indirect force, there is a period of unconsciousness immediately supervening which may last from a few moments to as many weeks. The face is pale, cold, and often moist; the pupils usually dilated, reacting to light; the pulse full, compressible, between 70 and 90; the respirations free; the temperature subnormal, and the blood pressure below 110. There is no involuntary evacuation of fæces or urine, and the patient lies quietly. A period of reaction soon occurs, the skin becomes warmer, the pulse firmer, the person may become restless; he can be aroused by a vigorous shaking and perhaps give monosyllabic answers to questions shouted in his ear. In a case in which the contusion is slight or mild, the mentality is impaired for a brief period, and in an hour or two he may give intelligent answers and in other respects appear responsible. Headache and nausea may be an accompaniment, with mild constitutional symptoms.

The severe contusions are worthy of the greatest consideration, and the period and degree of uncon-

\*Read at the Emergency Hospital, Washington, D. C., November 14, 1910.

sciousness is the most reliable index of cerebral mischief. In the severe contusions of the brain, the coma is profound, pupils dilated or contracted, usually retaining the light reflex, pulse full, without a great variation from normal, breathing deep and even stertorous, feces and urine retained, dorsal decubitus and a cool moist skin. Vomiting is present in the great majority of cases. Bleeding from the ear is not an uncommon symptom, and contrary to the general opinion is not sufficient evidence to adduce the presence of fracture of the base, but more frequently signifies a rupture of the tympanic membrane only. Bleeding into the conjunctiva and from the nose is more dependable as a basal fracture sign. The reaction will be slow, occupying days. The coma is succeeded by an active, even maniacal, delirium, lasting from one to seven days, then a stage of irritation and imperfect judgment; later by a quiescent, calm period, but marked by inability to concentrate, a defective memory, and a lack of original ideas. The conjoined periods may occupy several weeks, and the ultimate recovery is postponed several months. The blood pressure is low at first, followed by a rise. A period of unconsciousness, brief or prolonged, after a head injury, followed by coma, indicates plus cerebral pressure due either to hemorrhage or oedema, and often can be foretold by the sphygmometer. The conscious period may be a few moments or even twenty-four hours, and a number of cases have been reported in which individuals have received cephalic injuries and afterward completed a day's work seemingly well, and shortly after expired from the effects of hemorrhage. Traumatic cerebral hemorrhage without fracture is not uncommon. An excessive rise of blood pressure is a reliable indication of compression.

Gorin quotes Phelps as saying: "The loss of consciousness which immediately succeeds a cephalic injury is always the result of a diffuse cerebral contusion. If unconsciousness is preceded by a conscious interval, however brief, or if after restoration of consciousness to unconsciousness soon recurs, it is occasioned by some form of intracranial pressure. . . . It will be recalled that the recurrence of unconsciousness after an early interval of sensibility is indicative of an increased or supervention of hemorrhage, and that at a later period more or less conscious intervals in a general unconsciousness results from lessening from time to time of the hyperemia or oedema of a diffuse cerebral contusion."

Symptoms dependent on increased pressure in the brain are not so frank as those of apoplexy, but a close examination will probably reveal sufficient grounds upon which to base a sound diagnosis. Paralysis may be slight, monoplegic, hemiplegic, or limited to a group of muscles. Spasticity of a limb or few muscles is valuable and the comparison of the tendon reflexes is of much assistance; an increase is likely to be noted in the affected region. The Babinski sign may be present. Focal symptoms dependent of the cranial nerves will likely be absent, and anesthesia without paralysis is rare. The alteration of the stereognostic sense will likely be noted in some cases. The temperature will be

elevated after the initial fall, and a considerable rise is an unfavorable symptom. A very slow pulse becoming rapid or a rapid pulse becoming very slow are alarming symptoms and often precede dissolution.

*Diagnosis.*—The diagnosis rests on the degree of unconsciousness, alteration in the reflex arc, and motor nerves, consideration of temperature, pulse, and blood pressure. The differential diagnosis is not made easily, and it becomes necessary to exclude opium poisoning, alcoholism, apoplexy, uræmia, diabetic coma, epilepsy, and hysteria. It so often happens that an individual suffering from any one of these conditions may have the odor of alcohol. Likewise it may be impossible to determine if the onset of the coma resulted from a fall or vice versa. Only by a careful elimination, one by one, can a diagnosis be arrived at. The uranalysis is often misleading, as in old persons casts and albumin are frequently found, and in others after drinking bouts the amount of urea in a given specimen may be 0.2 per cent. instead of two per cent.

*Prognosis.*—The prognosis regarding life in the majority of cases is good. Moderate degrees of unconsciousness are compatible with a perfect recovery, and even a comatose state lasting from six to ten days often has a happy termination. Rise of temperature, great acceleration of the pulse, Cheyne-Stokes respiration, irresponsive pupils point to an unfavorable outcome.

The remote effects may be transient or permanent, and among the most serious is epilepsy, usually of the Jacksonian type. It is not necessary that the skull be fractured in order to produce this condition, as noted in a case reported by Starr. Such cases are not numerous enough to cause great apprehension, but the possibility must ever be borne in mind, as this deplorable sequela is not always amenable to surgical interference. The earning capacity of the individual who has suffered from a cerebral contusion may be materially lessened. About five per cent. of men who have had this lesion are unable to follow their occupations, while from ten to fifteen per cent. earn less than formerly. Seventy-five per cent. return to their trades, though not entirely free from subjective symptoms. It has been estimated that fifty to ninety per cent. of severe injuries to the head, including fractures, always bear a stigma as the result of such a trauma, in the form of headache, vertigo, changes in taste and disposition, alluded to by Bailey as *cerebrasthenia*, a term denoting a "diminished functional power, without impairment sufficiently to be called insanity. The prominent symptoms are headache, dizziness, irritability, insomnia, changes in temperament, lessened mental activity, and intolerance to alcohol.

Possible headache is one of the most sensitive and distressing symptoms. It may be frontal or occipital, likely to be dull, and throbbing. Dizziness upon standing or stooping, often due to men working upon buildings in close and hot ventilation. Irritability is especially prone to be present upon occasions when considerable stimulation is necessary. The individual is annoyed by trifles which previously would have been unnoticed. The condition becomes plain to the friend. Even the

disposition changes, and lifelong habits may be changed after cerebral contusion. A person of sunny temperament may become morose, and a spendthrift may develop miserly habits. The diminished capacity for intellectual work is noted and a sense of oppression, both physical and mental, is common. Fatigue seems not to be limited to the brain. The intolerance of alcohol sometimes becomes striking, and a small amount of whiskey may make such a person hysterical or even maniacal.

The question of insanity is an important one, but probably overrated. Much less than one per cent. of insane cases can be traced directly to cerebral contusion. We cannot accept each case of insanity, in which is given a history of a blow some time inflicted, as one of traumatic insanity, as there is scarcely any one who has reached adolescence, however sane, that cannot recollect having had a blow upon the head. All in all, the condition of cerebraesthesia is transient in about seventy-five per cent. of the cases, but in the remaining twenty-five per cent. a legacy of some description is seen. It is conceded that in those persons with a hereditary taint the occurrence of insanity after cerebral injuries is more frequent. The form of insanity is variable.

*Treatment.*—The treatment of cerebral contusions must consider the immediate and urgent symptoms first. Moderate stimulation, preferably with strychnine, rest, ice cap to the head, and hot bags to the body are indicated in the shock attendant upon this condition. Should active or maniacal delirium be present, it is best controlled by hyoscine and the bromides. In the milder cases rest in bed, purgatives, and sedatives are all that is necessary. In my hands morphine has not given good results, and is generally contraindicated, as there is a tendency to produce cerebral congestion. In the more profound cases, close observation is necessary and symptoms of pressure should be met by prompt trephining. Should the indications be those of arterial extravasation, trephination over the middle meningeal is the course to pursue. Should no injury be found, the use of the trephine on the opposite side is justifiable. The operation is not attended with much risk. In cases showing no focal symptoms, with nausea present from the beginning, rising pulse, and temperature, an opening should be made in the injured side, the dura opened and drained. If the appearance is normal, trephine on the opposite side, following the same technique. It is not well to postpone operative interference too long, as this simple procedure may be followed by the happiest results if practised early. Should the oedema have become general the outlook is bad. Corner reports the case of a compound fracture of the vault; a week had passed without symptoms, but at the end of this time the child became drowsy and finally unconscious. The diagnosis of extradural abscess or meningitis was made. With the horseshoe flap, the dura was exposed and found to have been wounded. It was incised, the brain was bulging, and the trocar did not locate pus. The brain was pale and oedematous and not inflamed. It was a condition which many did not believe in, and to which had been given the name

"spreading oedema." It is not necessarily of septic or infective origin, and has its analogy in cellulitis in other tissues. The prognosis is grave.

Bloodletting is of questionable value, as the compensatory high pressure in the general circulatory system is not present in the cranial cavity. Frazier states that venesection is of little avail, as determined upon animals to overcome cerebral anæmia.

Lumbar punctures may afford relief in this condition, but after considerable pressure has accumulated in the cranium the medulla is forced down into the foramen magnum sufficiently to act as a wedge and cut off free exchange of fluid in the spinal canal and brain ventricles. The efficiency of the ice bag can be questioned also. A large proportion of cases of cerebral contusions run a limited course and will recover without treatment, but in the severer ones surgical methods are the ones to be considered curative.

The treatment of cerebraesthesia is along lines to improve the general health—fresh air, sunlight, good food, and attention to the bowels. The bromides may be useful. Those cases showing a tendency toward hypochondriasis are often benefited by resuming work as soon as the physical condition permits.

The cases I wish to report are but two selected from a large number, and both of very recent date:

CASE I.—D. S., a child of seven years, was knocked down by a vehicle on October 22, 1907, his head striking the pavement. He regained his feet, seemed conscious that he was hurt, and told some one to send for the physician who generally treated him in his illnesses. He was brought to the Emergency Hospital in a restless, semiconscious state. A contusion was found over the right parietal bone, with no apparent depression. The child became quiet and could be aroused with difficulty; the pupils were regular, temperature normal, the dorsal decubitus assumed, and paralysis absent. In view of the approaching coma, trephining was deemed advisable and performed about two hours after admission. A flap was turned back to expose the skull under the contused scalp. A stellate fracture was found without depression, and a linear fracture extending from this point over the vault and involved the left parietal to what extent is unknown, but the line was followed almost to the level of the left ear. A button of bone was removed from the right parietal, the dura opened and drained. The amount of cerebrospinal fluid which escaped was small and not bloodstained. The boy reacted in about twelve hours and made an uneventful recovery. I am convinced trephining relieved an impending oedema.

CASE II.—M. W., male, white, seventy years, was struck by a car November 4, 1907, receiving a lacerated and contused wound of the scalp in the right frontal region. He seemed unconscious when first attended by the ambulance surgeon, but before the hospital was reached he was able to give a fair statement of his name, address, residence, etc. His general condition was very good. The following day there was some mental confusion, no paralysis, good pupillary reaction, pulse between 74 and 80, and temperature 99° F. or less. On November 6th he was worse; there was delirium, followed by a state of lethargy, from which he could be aroused. No focal symptoms were present. His pulse rose to 100, and temperature reached 100° F. in the afternoon. His blood pressure was 200 at 4 p. m. The coma deepened, and he died about 5 p. m.

The autopsy, made under the direction of the coroner, was typical of cerebral contusion with hæmorrhage by contracoup, as the notes made at the time indicate. Inspection revealed a small lacerated scalp wound three inches above the right supraorbital ridge, one inch external to the median line. Reflection of scalp showed slight hæmorrhage in the immediate vicinity of the wound, and a small amount of blood oozing from a foramen in the occipital bone near the vertex. No fracture of the vault was present. After removal of the upper portion of the

cranium, a considerable extravasation of blood under the pia covering the cerebellum and both lower occipital lobes, decidedly marked, however, over the lower left occipital region, at a point diametrically opposite the scalp wound. The cerebellum was covered with plastic lymph. On section the cerebellum was cut with little resistance and gave evidence of degeneration. It also exhibited extensive extravasation of blood into the lobes. At various levels the cerebrum was the site of numerous punctate hæmorrhages, very evenly distributed. The ventricles contained a sanguinous fluid. After removal of the brain, the presence of blood in the middle and posterior fossa was observed, but no basal fracture was present.

#### Conclusions.

My general conclusions are:

Cerebral contusions, when fatal, are due to laceration or hæmorrhage.

Prolonged coma is a reliable indication of increased pressure.

A conscious period followed by coma indicates hæmorrhage.

High blood pressure is an early and reliable symptom of pressure.

Trephining is indicated in plus intracranial pressure from hæmorrhage or œdema.

Venesection is of doubtful value.

FIFTEENTH STREET AND OHIO AVENUE.

#### HOSPITAL DIETETICS.

By DUDLEY ROBERTS, M. D.,

Brooklyn, N. Y.,

Associate Physician, Brooklyn Hospital.

As the standing committee on diet at the Brooklyn Hospital it has devolved on the writer to make somewhat of a study of the general question of hospital dietetics in its varied aspects. The systems in vogue in different institutions vary widely; there are those encumbered by a most complicated system of individual ordering; on the other hand, many institutions run their dietetic affairs with no discoverable system and about as little consideration of the scientific aspect of the problem as is given to the average boarding house table. It is true that the system must be suited to the equipment and service of each institution, but it has seemed to me many institutions conscious of these difficult problems may find in our experience a partial solution of some of their troubles.

Were economy unnecessary the ideal plan in the preparation of food for the sick would be the separate preparation of each individual dietary to appeal to the individual taste while meeting the requirements of the condition. Economy of the strictest kind is usually necessary, and it demands that kitchens be reduced to a minimal number, preferably one, and in this one there be a division of labor suiting the worker to the work with consequent saving. Waste of material and labor is very evidently proportionately less when food is prepared on a large scale.

From the standpoint of economy it is important that the work of food preparation be equally distributed throughout the day. If the principal meal of all inmates and workers be served at the same hour, a larger kitchen force is required at that hour than at any other time, and the equipment must also

be greater. A simple arrangement in accordance with this principle has been instituted by Miss Osborne, the valued executive head of the Brooklyn Hospital: Dinner for ward patients and help is served at 12 noon; luncheon for private patients and staff is served at 1 o'clock; supper for ward patients and help is served at 5 o'clock, and dinner for private patients and staff at 6:30 o'clock. Such an arrangement reduces the necessary force to a minimum and makes for better order in the kitchen at all times.

The arrangement of a comprehensive system of diet lists is advantageous in many ways. If through a system we are able to supply proper food to the majority of patients in need of no especial dietetic care, our efforts can be spared for those distinctly in need of the most painstaking attention. The *per diem* cost of food for an institution is a matter that is very largely under its direct control. The question resolves itself into just how much it is possible to expend for food materials, and how much equipment and labor it requires to prepare it. By the employment of more competent caterers and cooks an actual saving may be accomplished, the more economical foods can be agreeably prepared.

Any system of diet lists must be constructed with the idea of having one general house diet suitable for the large proportion of patients. This makes for economy and obviates the necessity of unnecessary individual dietetic ordering. Such a diet list, then, must be made up of preparations suitable for the average taste and needs. It must be sufficiently nourishing. It must have no undesirable action on the gastrointestinal tract or other parts of the body. It may be said that hospital dietaries are usually too constipating, and this is entirely unnecessary. There are natural cathartics cheaper than drugs. Any diet should be changed from day to day to avoid tiresome sameness. Finally, its components should be, in some part at least, suitable for those diet lists that may be spoken of as lighter; this applies, particularly to soups, desserts, and meats.

In arranging the diet lists of lighter grade it is essential that the importance of regularity in amount of food and times for its administration be borne in mind. Patients on light diet are not obtaining much nourishment, and if such matters are left to the discretion of the untrained, serious harm may be done. The diet lists of lighter grade must have, however, a certain flexibility. It should be possible to use any one absolutely, or if conditions demand it should be amenable to changes at the discretion of those in charge. The natural transition is from liquid nourishment gradually to more solid and nourishing preparations.

If any system of diet lists is to meet the purpose of its construction it is absolutely necessary that it be understood and adhered to by all responsible for its preparation, administration, and ordering. I have often found that those who should be entirely familiar with the established system are grossly ignorant of its provisions. A patient ordered on a certain diet in one ward receives a very different diet from that given in another. By the use of

printed lists on folding cards this difficulty is overcome; each nurse, each orderly, each executive head knows the diet of the institution.

For the more definite instruction of the staff it has been found convenient to have typewritten copies of the day's menu in the hands of each head nurse, while the staff is making house rounds in the morning. Certain food preparations, as the soups, the meats, the breads, and desserts, are changed from day to day, and those which on a particular day

preparations listed are usually well borne. The meals are all made small and frequent. To the fluids ordered between meals special articles may be added at the discretion of the staff and attending physician. By the restriction of certain articles and the addition of others it is possible to suit this list to a considerable proportion of patients needing careful attention. The diet list of private patients is necessarily more liberal and expensive.

The trouble lies often far less in the food than

#### BROOKLYN HOSPITAL DIETARY.\*

1. The original list this special list appears on the other side of the card for convenience in handling.  
2. Doctor will send sample cards on request.

are found to be unsuitable for a certain patient are ordered omitted and other preparations substituted from a list of alternatives. By such a system the diet of every patient is under the direct daily control of the proper authority.

Only certain brief comment on these tables is necessary. Diet No. 5 has been constructed to meet the demands of the surgical staff for suitable fluids to allay hunger and thirst. Nutritive and consequently fermentable content has designedly been omitted.

The fluid diet designated No. 3 has much to recommend it in place of plain milk. It offers some variety and appeals to some averse to taking milk. The cereal admixture increases digestibility and nutritive value. So well are these gruels borne that they may be given at every feeding. They are easily made by adding the well cooked cereal to hot or cold milk, salting later to taste.

The convalescent diet has been arranged with the idea of supplying a highly nutritious diet in concentrated form, free from articles of doubtful digestibility. Of course this term is merely relative. The

in the accessories. Attention must largely be devoted to the judicious betterment of things making an indirect appeal to the gustatory organs.

84 REMSEN STREET.

#### THE CAUSES OF APPENDICITIS.\*

BY ALFRED W. ARMSTRONG, A. B., M. D.,  
Canandaigua, N. Y.

It is probable that more has been written on the subject of appendicitis during the past ten years than has ever been written concerning inflammation in any other part of the body. The diagnostic signs have come to be well known and the treatment differs, with the best men of the profession, only in minor details, but there seems to be a wide variation in the opinion of those who see the most of these cases in regard to the etiology of this common disease.

As predisposing causes of appendicular inflam-

\*Read before the Society of Physicians of Canandaigua, November 1, 1907.

mation should be mentioned: 1. The degenerate condition of the organ itself. 2. The structure of the appendicular walls and their blood and nerve supply. 3. Its form and direction. 4. Normal drainage. 5. Diet and chronic constipation. 6. Mechanical obstruction and stricture of the lumen. 7. Constitutional diseases. 8. Disease of the pelvic organs.

The list of exciting causes is shorter, including as it should: 1. Traumatism. 2. Intestinal parasites. 3. Enteritis. 4. Direct infection.

The appendix persists as the remains of the larger cæcum of lower animals an anatomical protest against vegetarianism. From the standpoint of evolution it would appear to be becoming obliterated. It represents a portion of the intestinal canal which, at an early period of fetal life, was a continuation of and differed little from the colon. At a later period its development ceased, and it then became merely an appendage of the cæcum, with an inherent tendency to degenerate.

In structure the appendix resembles the other parts of the intestine in possessing four coats, but differs in its minute anatomy. Its mucous lining is crowded with solitary lymphoid follicles; thus inviting infection; the muscular coat is scanty, and between its scattered fibres direct communication is permitted between the submucous and the serous coats. Inflammation of the mucous membrane may therefore spread without hindrance to the peritoneum. The blood supply is derived from the ileocolic branch of the superior mesenteric artery. In the female there is an additional supply from the right ovarian artery, and this is thought by (1, 2) some to account for the fact that appendix disease is less common in women than in men (3). At best the blood supply is poorer than that of other parts of the intestine, thus making it less resistant. The nerve supply is derived from the superior mesenteric plexus. Any conditions which bring about a change in the blood or nerve supply, such as kinking or bending of the appendix or twisting of the mesentery, embolism, or thrombosis of the vessels, tend to weaken the resistance of the organ and invite inflammation. In early life the appendix possesses a canal which is continuous with that of the cæcum, but in later years this connection is sometimes cut off, and in many cases partial or complete occlusion takes place, this tendency increasing with the age of the patient.

The normal appendix, if such an organ exists, varies in length from 1 inch to  $9\frac{1}{2}$  inches, in diameter from  $\frac{1}{8}$  to  $\frac{1}{2}$  an inch. Many congenital variations of form occur. The club shaped, long, narrow or short, thick, kinked or twisted appendix, is the result of accident or of degeneration of this rudimentary organ. Hence a person may be destined from birth to have appendicular inflammation, if subjected to certain exciting causes. These irregularities are, like many other minute anatomical peculiarities, hereditary, and that may explain the apparent hereditary features of the disease. Personally, I have observed within a year two patients, sisters, who had similar attacks of appendicitis in which there was a striking resemblance between the two appendices, both anatomically and pathologically. A long appendix is more likely to

become twisted or kinked. As to direction, the appendix may lie in almost any axis. Authorities do not seem to agree upon the most common position, but the (4) four positions, "inward," "behind cæcum," "downward and inward," and "into true pelvis," will, without doubt, include 90 per cent. of the cases. The ætiological importance of this rests in the supposition that appendicular inflammation is more commonly met with when the appendix is so placed as to admit material which is with difficulty expelled—that is, when it is directed inward or downward.

The mucous membrane of the cæcum is continuous with that of the appendix, and the secretions from the latter are drained into the intestine through the narrow opening, which may or may not be guarded by a fold of mucous membrane, known as the valve of Gerlach. Holmes, in his monograph on appendicitis, places particular emphasis upon the construction of this valve. He states that the normal congenital construction of the valve is a constant menace to health, and believes that any increase in this narrowing of the lumen, as by external traumatism, unusual activity of the muscles of the cæcum, or injury of these muscles, or congestion by impaction of fecal material and its subsequent dislodgment may bring about a condition of appendicular inflammation. "An abnormal construction of the valve may admit foreign material and prevent its exit." This valve was described by Gerlach in 1847 as a "semilunar fold of mucous membrane guarding the appendicocæcal orifice." Some present day (5) anatomists declare that it is "inconstant and unimportant" (6), others deny that it ever exists (7). Treves does not mention it in his *Applied Anatomy*. That which concerns us most as clinicians is the fact that normal drainage is essential to the health of the appendix, and anything which lessens the calibre of the lumen may prepare the way for an acute attack.

Chronic constipation contributes its share to the causation of appendicular inflammation in a somewhat indirect way. Hesitation in the passage of fecal matter along the intestinal tract allows more time for decomposition and the multiplication of bacteria. The increased pressure in the colon may force material into the appendix, which, owing to the position of the organ, the weakened condition of its walls or resultant swelling from slight traumatism, cannot be returned. This condition, present within the appendix, is ready to furnish the fuel for a conflagration when acute conditions demand. However, statistics do not seem to show that appendicular inflammation is common among races who are subject to constipation. In an editorial in one of the current issues of the *Medical Record* (8), the editor quotes statistics to show that inflammation of the appendix is very rare among Orientals, in whom constipation is very common. One observer, Dr. Naby, reports that out of 6,800 natives of Mesopotamia, who suffered from various diseases, only two had inflammation of the appendix. This would seem to suggest that constipation in itself is inadequate to cause the disease. On the other hand there are those who believe that there is an unmistakable relationship between meat eating and appendicular inflammation. It is stated

that it is the excessive eating of meat that causes the white races to lead in the statistics of appendicular disease, and that the increased consumption of meat in Germany has been attended by a considerable increase of morbidity from appendicular inflammation. Nothing is said of the way in which this is brought about, and until the pathology is explained the mere fact that the increase in the consumption of meat and the number of cases of inflammation of the appendix has been constant, does not make the one the cause of the other.

The presence of foreign bodies within the appendix may often be looked upon as accidental and insignificant as regards the causation of inflammation, but the variety of substances found is interesting. The following are a few which have been recorded: Pills and capsules containing medicine, seeds of various kinds, gallstones, portions of peanut, pins and needles, pips and skins of fruit, cherry and date stones, hair, bristles from tooth brush, intestinal worms, fish bones, faecal concretions, and shingle nails. Personally, I have observed many of these substances within the appendix, and one case seen recently through the courtesy of Dr. Clapper and Dr. Beahan illustrates the variety of seeds which may be stored up in this little organ. There were six grape seeds, three tomato seeds, three raspberry seeds, several strawberry seeds, a tooth brush bristle, and several very hard masses resembling gallstones, all in a large amount of faecal matter. The appendix was  $5\frac{1}{2}$  inches long, of large diameter, and directed downward. A few hæmorrhagic areas were present along the mucous membrane, where the concretions were located, and the lumen was large and free from scars or constrictions.

The coexistence of an ovarian hæmatoma brought up the question of relationship between the two conditions. It is not improbable that the long, heavy appendix brought about the condition of the ovary. It seems more likely, however, that there was no cause common to the two conditions. Out of a series of 124 autopsies made by Bryant for other reasons than disease of the appendix, 67 per cent. contained abnormal material. One case is reported in which 150 bird shot were found in an appendix which was apparently free from disease.

The presence of concretions or of foreign material large enough to obstruct the lumen or injure the walls is without doubt most important. A scar once formed within the appendix never ceases to be more or less of a hindrance to the free passage of faecal matter in and out of the organ. Van Zwelenburg has reported some interesting experiments upon living dogs, which seem to establish some facts concerning this subject. He was able to produce typical inflammation of the appendix in the dog only when three conditions were met: constriction or obstruction, distention, and the presence of a pathogenic germ. The frequency of necrosis or gangrene indicates mechanical obstruction. Simple infection does not produce gangrene. The condition of distention is present in the early history of every case. If the obstruction is soft or small enough, the pressure within the appendix may become sufficient to force it back into the bowel, and the symptoms will gradually disappear. If the

course of least resistance is not in the direction of the cæcum, it is only a question of time when gangrene will destroy the wall and a perforation result. The concretion may form a sort of ball valve which will admit fluids and prohibit their escape. Once closed the appendix continues its attempts to empty itself and appendicular colic results.

It is such a common thing to find appendicular inflammation as a complication or sequel of various constitutional diseases that these primary conditions are often named as causes. They should be mentioned as predisposing causes only, for it is not likely that any one new germ is introduced into the body for this purpose or that any novel condition is brought about by any of these diseases, but if the proper conditions prevail within the appendix, any one of these conditions, by its weakening influence upon the entire body, might precipitate an attack. True it is moreover that (9) measles, la grippe, rheumatism, typhoid fever, fatigue, digestive disturbances, exposure, excessive physical exertion, and improper food, not infrequently precede an appendicular storm.

The frequency with which disease of the pelvic organs is associated with appendicular inflammation is interesting, and it is often impossible to say which is cause and which is result. It is not at all uncommon to find the appendix firmly adherent to the fallopian tube, the ovary, or the broad ligament. If it is evident that the inflammation has begun on the outside of the appendix, it would seem that the pelvic condition originated the trouble, but if the disturbance is within the appendix it is hard to understand why the pelvic condition should be blamed.

Traumatism, whether from a blow upon the abdomen over the appendix, or brought about by a strain upon the muscles, which may pinch the organ and interfere with its circulation, must be dealt with in this discussion. Pressure upon the intestine, as by the act of lifting when the body is in a certain position and conditions are right within the bowel, might easily force material into the appendix which could not be expelled. The frequent occurrence of appendix disease in nurses, waiters, and others who must do considerable lifting, especially among those who have given up a sedentary occupation for this work, is significant.

Intestinal parasites are, without doubt, present in the intestinal tract more frequently than many physicians believe, and some of our best men, including Dr. Stockton, of Buffalo, hold them to be a not infrequent cause of appendicular inflammation. One case reported in the *Hospital Record* for February, 1906, was operated, at the Canandaigua Hospital, where it was found that the appendix contained more than fifty pin worms, which had without doubt been the exciting cause of the inflammation.

Enteritis, especially when it occurs during the summer months, when indiscretions in diet, especially along the line of fruits and vegetables, and the eating of foods, which are, for want of proper care after coming into market, in an early stage of decomposition, would be agreed upon, perhaps, as the condition which is most often present at the beginning of acute inflammation in the appendix. It

has seemed to me that the very worst cases are those which develop while a condition of enteritis exists. The infection seems to be of a more virulent type, and many cases of general peritonitis are found, even though the case is operated early. The condition is more difficult to interpret, and operation is sometimes delayed beyond the point of safety, because bellyache has been considered to be a rather unimportant symptom, constant in enteritis. It is not uncommon, moreover, to find cases in which the history will reveal the fact that early in the attack, with the diagnosis of "acute indigestion" clearly made, an anodyne has been given to relieve the pain, and the symptoms have been masked, while the ravages of the infection have been going on in the appendix, and the patient's life endangered while he is enjoying the effects of the opiate which is killing him. Bellyache *does* mean a great deal at the present time, and in but few instances should it indicate the use of the hypodermic of morphine.

After all this discussion of conditions, real and imaginary, known and unknown, it remains to be said, that the presence of a pathogenic germ is the one thing constantly necessary to the production of this condition. Simple necrosis of an organ so functionally inactive and useless as the appendix would not be expected to give rise to serious symptoms, it must rather become infected. There is no special germ, however, that can be charged with the burden of having been introduced into the appendix for this special occasion—in fact, the germs involved in the process are normally present in the appendix in health, awaiting the time when some accident shall bring about a condition suitable for their work. The *Bacillus coli communis* and the ordinary pyogenic cocci are most commonly present, and whatever the assigned cause may be it must be remembered that appendicitis is an infective malady.

## THE INSPECTION AND CHEMICAL EXAMINATION OF THE BALTIMORE MILK SUPPLY.

By WILLIAM E. HOFFMAN, JR., PH. D.,  
Baltimore,

Chemist to the Baltimore Health Department.

During the past year there have been consumed in Baltimore, as nearly as can be estimated, about ten million gallons of milk. The supply comes almost entirely from the farms and dairies lying within a radius of thirty-five miles of the city, the majority coming from the near vicinity of Baltimore. Until recently there were cows kept even in the city, but since the introduction of a clause prohibiting this, there is no longer any such state of affairs. The physical condition of the cows and

the sanitary condition of the dairy farms outside of the city limits are under the control of the State Board of Health and the State Live Stock and Sanitary Board.

The working force for the examination and control of this milk supply is provided by the city through the Health Department, and consists of a chemist, his assistant, and two inspectors. Each inspector every morning visits one railroad station, and there, with a lactometer, examines as much as is possible of the milk while the cans are being removed from the incoming trains and reloaded onto the dealers' wagons. If, in the judgment of the inspector, the quality of any of the milk does not meet with the requirements of the law (which are 1.029 specific gravity at 60° F., three per cent. fat, twelve per cent. solids), he spills it, after having taken a sample for analysis in the laboratory. He then marks these empty cans with a conspicuous tag stating the reason for spilling, and returns them to the shipper. Also, if any cans are unclean or if the milk is in any way unfit for use, it is spilled. In addition to examination with the lactometer, each inspector collects at least six samples from the station at which he may have been and delivers them to the laboratory for analysis.

After having finished the work at the stations, the inspectors then cover certain districts of the city, examining the milk at dairies, in wagons, and at all places where it is sold, and carefully looking into the conditions under which the milk is kept. Samples are obtained from these places, when deemed necessary, and taken to the laboratory for further investigation. In cases where certain milk supplies are referred to the Health Department for investigation, an inspector is especially detailed to do this work and to make a report on the results.

In the samples which are brought into the laboratory by the inspectors, determination is made of the specific gravity, fat, and total solids, and of the presence or absence of preservative or artificial coloring matter.

Since the early summer of 1907, all those cases in which a preservative was used have been prosecuted, and the results have shown that as a rule its use was without any malign purpose and through ignorance of injurious effects. During the three summer months of 1906, fifty per cent. of the samples of milk analyzed were found to contain preservatives, while in the summer of 1907, after the publication of the first few prosecutions, less than three per cent. of the samples analyzed contained preservatives. Through the cooperation of the Maryland State Board of Health with the city Health Department, prosecutions for this offense have been rigidly carried out. As a result, the producer has been shown that it is better policy for him to be particular and to take proper precautions in the care of milk, than to rely on preservatives and thereby run the risk of a fine with the attending publicity.

In the past year, of the ten million gallons of milk consumed, about twenty per cent. was inspected, and five thousand samples were analyzed. Of course, a vast amount of work remains to be accomplished before Baltimore can have a pure milk supply, but toward that end a beginning has

been made. In previous years very little attention was paid to the condition of the railroad cars in which milk was shipped to the city, but during the past year this phase of the question has been taken up, and at the present time the sanitary condition of these cars is fair. In fact, no further improvement can be made in this direction until the railroad companies can be induced to provide refrigerator cars. Then, too, the sanitary condition of all the dairies and small stores, where milk is sold, is being investigated, and the owners are being instructed as to the proper way to remedy existing evils.

The system of inspection and control, in its present state of progress, is very imperfect. However, by a new set of laws and ordinances, which has been compiled from those of the principal cities of the United States, and which is soon to come up for consideration before the city council and State legislature, it is hoped to overcome in the near future the difficulties, and to improve vastly the quality of Baltimore's present milk supply.

15 SOUTH GAY STREET.

#### OBSERVATIONS MADE AT THE BIER CLINIC IN BERLIN.

BY MARY HESS BROWN, M. D.,  
New York.

As this treatment had been the subject of much discussion in America, at the suggestion of Professor Prausnitz, of London, and at Professor Bier's invitation, I went to Berlin the latter part of July to see the practical demonstrations of Professor Bier and his assistants, Dr. Klapp, Dr. Schmieden, and others. Dr. Schmieden speaks English fluently, so if your German vocabulary is limited, you still find it worth while to take time to visit the hospital daily and see the patients being treated in the wards and dispensary.

CASE I.—One of the first patients seen was an acute case, a patient with an infected scalp wound, fracture of superior maxilla, and destruction of right eye. In the very beginning a prophylactic dose of antitetanic serum had been given. The patient had a high temperature. Passive hyperemia of head was produced by applying a rubber tape about one inch wide about the neck, an ordinary hook and two eyes being first adjusted to either end of tape, so that it could be applied and held steadily in place, yet not with discomfort to the patient. Gauze pads were placed under the tape where it crossed the great vessels, so undue pressure would not be exerted over them. The red hyperemia gradually appeared and caused no pain or alteration in temporal pulse, and sleep ensued. This dressing remained in place for eighteen or more hours out of the twenty-four, the patient always being advised to inform the nurse as soon as it became uncomfortable. Each succeeding day the tape was applied for a shorter length of time, as patient slowly but definitely improved, and in one week the temperature was normal and the use of rubber tape was discontinued. Simple aseptic dressings were used for face, and no strong, antiseptic solutions.

CASE II.—The second case was that of a young laborer who had suffered from a lacerated wound of the forearm. When the accident occurred the skin was very dirty, and, of course, an infected wound was imminent. The wound, however, was thoroughly sutured and a rubber bandage applied above the elbow, which remained in place for eighteen hours out of the twenty-four. The red hyperemia, of course, followed the application of the bandage, together with swelling of the forearm, but as the pain diminished the elevated temperature decreased, and pulse was not altered; the bandage was continued, sometimes being re-

moved and reapplied in a slightly different location. The discharge from the wound was not drained by gauze or strips of rubber tissue, but a cup was applied, and by means of suction all the discharge was removed.

The cup may be applied for four or five minutes, then removed and reapplied, continuing this process for about forty-five minutes, this generally sufficing for twenty-four hours. While the rubber bandage and cups are applied, a simple, loose, sterile dressing covers the forearm, but no firm dressing.

Each day the condition of forearm improved, and the temperature decreased, thus avoiding the necessity of opening the wound, which would no doubt have occurred under the old method treatment. The patient was encouraged to move his fingers, and when I last saw the case, about two weeks after injury, the temperature was normal most of the day, and induration had almost entirely disappeared; the function of forearm and hand being perfect.

The cupping is the second hyperæmic method used by Professor Bier, and thus avoids drainage by gauze, etc., which no doubt has many times caused the tissue to become necrotic. The cupping glass in this way saves the long, free incisions, especially in cellulitis and mastitis cases, for the discharge can be drawn out through the small openings.

CASE III.—The next acute case, which seemed marvelous in the light of the old methods of treatment, was a gonorrheal wrist joint, together with involvement of metacarpal joints, with acute pain, edema, and redness. A hypodermic injection of morphine had previously been given to quiet the patient, who was a strong, robust young woman, but after the application of the rubber bandage above the elbow all pain ceased, and the patient was encouraged to use her fingers to some extent, which she did, without discomfort. The dressing remained on the arm for most of the twenty-four hours and patient was quiet and happy. Elevation of temperature gradually subsided, and duration of application of bandage lessened.

I must not neglect to speak of the acute mastitis cases, only a stab incision being made when pus was suspected, and a large cupping glass with the rubber bulb to exhaust the air and cause suction. The glass, of course, is boiled before application, so it is perfectly sterile, and sterile petrolatum is applied to the edge of glass. The suction is continued for forty-five minutes, the cup being reapplied every five minutes. The application is made generally only once a day, although it may be used twice. The breast is thus saved from numerous sweeping incisions, and often the infant can nurse without any danger whatever.

Large carbuncles, which formerly had always been incised with a sweeping cut, were stabbed and a cupping glass applied with most excellent results, with much less destruction of tissue and less pain.

The chronic conditions were no less interesting, but, of course, a longer observation would have been more satisfactory.

CASE IV.—A tuberculous knee joint with contractures was treated first by an extension apparatus to reduce the contraction, and the application of a rubber bandage above the knee for one hour, twice a day, which caused no pain or discomfort and no change in the pulse. The joint was not immobilized, but passive motion was undertaken to some degree; however, old adhesions were not broken up, for extravasations of blood into the joint would only cause new adhesions to form. The child was allowed to walk on crutches, and thus keep the foot from the floor. The joint was freely movable and the general condition of child much improved, although I only observed the case for two weeks.

Professor Bier's theory is not that tuberculosis

January 11, 1908.]

causes destruction of the joint, with ankylosis as a result, but treatment by immobilization produces it.

CASE V.—A tuberculous elbow with an open sinus was another case. The sinus was cupped each day for a period of forty-five minutes, reapplying the cup every few minutes, with the result that the elbow was improving. The patient knitted, thus using her elbow joint some, but not tiring it.

The third method of passive hyperæmic treatment was the use of a hot air chamber, which I saw used in an ankylosed joint after an old fracture and after an old dislocation.

One case of arthritis deformans was very much benefited by the hot air treatment.

541 WEST ONE HUNDRED AND TWENTY-THIRD STREET.

### Therapeutical Notes.

**Injections of Calomel for Syphilis.**—At a meeting of the Société de thérapeutique, held November 10, 1907, and reported in the *Bulletin* (cliv, No. 21), M. L. Lafay advocated the use of a 40 per cent. solution of calomel in a specially prepared oily excipient as a desirable substitute for the grey oil commonly used of late for the hypodermatic administration of mercury in the treatment of syphilitic conditions. The calomel employed must be of the purest quality in the finest state of subdivision and have been washed with pure sulphuric ether free from water. It is important to use a completely dehydrated ether; the ordinary sulphuric ether, or the alcohol (boiling) used in Italy will not answer the purpose, according to the author. In the operation of levigating and washing the calomel care should be taken to exclude light, which has a redreasing action on it. The excipient consists of a mixture of anhydrous wool fat and pure liquid petrolatum (albolene), containing 5 per cent. of camphor. The author does not add any anæsthetic, since it has been found that anæsthetics, such as guaiacol and others, are absorbed and dissipated a long time before the pain of the injection begins to be felt. The formula employed by Lafay is as follows:

R Calomel, finely levigated, and washed with ether, . . . . . 0.40 grammes.

Woolfat, anhydrous, containing 5 per cent. of camphor, . . . . . 3 parts.

Liquid petrolatum (or albolene), containing 5 per cent. of camphor, . . . . . 7 parts.

Mix and sterilize.

Each cubic centimetre of the oil thus prepared contains 0.40 grammes of calomel, which represents the equivalent of 0.34 grammes of metallic mercury. It has the appearance and consistency of thick cream, is fluid at ordinary temperatures, and will keep indefinitely if not exposed to light. The author advises the use of a specially graduated syringe, the stem of the piston being spaced into divisions corresponding to 0.01 grammes of the medicament. The part into which the needle fits is calculated to measure 5 centimetres. The needle should be long and fine and of just as wide a diameter as will permit the passage of the oil; when the calomel is properly levigated a diameter of six tenths of a millimetre will be found sufficient. The doses usually employed were 0.08 grammes, 0.08 grammes, and 0.10 grammes.

Apart from the good results obtained with the

calomel injections, they were found to be better tolerated and decidedly less painful than injections made with the old formula.

**Calx Chlorinata Confounded with Calcium Chlorate.**—A note in a recent number of *Therapies der Gegenwart* directs attention to a source of danger in the prescribing of calcium chlorate. For a case of bleeding hemorrhoids a physician prescribed as follows:

R Calc. chlor. crystallizat. pur., . . . . . 40.0 grammes.  
Aque destillatæ, . . . . . ad. 200.0 grammes.

M.

The pharmacist committed the error of using chlorinated lime instead of calcium chlorate, and the result of the injection of such a solution on the patient may be imagined. Great pain ensued, which led to an investigation, when the cause of the trouble was discovered. The prescriber advises physicians to be careful to write out the name of the salt desired in full, followed in parenthesis by the warning, "avoid chlorinated lime." [We may remark that calcium chlorate is not to be found in American pharmacies, but a similar danger to that noted exists with regard to the possible ignorant substitution of calx chlorinata (so called chloride of lime) for calcium chloridum.—Ed.]

**For Acute Coryza** Boular employs a solution of atropine sulphate of a definite strength applied to the nasal mucous membrane by means of a swab. According to *La Clinique*, for September 6, 1907, he has employed this method in the case of adults for years with excellent results. The solution is made according to the following formula:

R Atropine sulphatis, . . . . . 0.001 grammes.  
Aque laurocerasi, . . . . . 20.0 grammes.  
Aque destillatæ, . . . . . 20.0 grammes.

M.

Absorbent cotton tightly wrapped around the end of a match [or wooden toothpick] is soaked in the solution and swabbed on the nasal mucous membrane, repeating every half hour at first, and then every hour if necessary, but not oftener than eight or ten times in the day. It is not advised to use the treatment where there is obstruction of the nasal passages.

**Treatment of Dyspepsia in Tuberculous Cases.** Renon (*La Quinzaine thérapeutique*, December 10, 1907) advises cutting down the diet and aiding the digestive functions by the administration of peptic ferments combined with a mild laxative and bitter tonic as in the following combination:

Pancreatium, . . . . . 0.20 grammes.  
R Peppermint, . . . . . 0.25 grammes.  
Powdered calomel, . . . . . 0.25 grammes.  
Sodium phosphate, . . . . . 0.20 grammes.

M. fine emulsion.

Sig. One after every meal.

**Ointment for Ulcer of the Leg.** An ointment which has given Danlos better results than all other means he has tried for the treatment of ulcer of the leg has the following composition:

R Ung. terræ peroxid. hydrat.  
Ung. atrament.  
Ung. oliv.  
Ung. pallas. confectio.

M.

This is applied in a thin, or better still, as a protective

## THE CLINICAL STUDY OF CANCER.

The *Fourth Report of the Caroline Brewer Croft Fund Cancer Commission of the Harvard Medical School* has recently been published, completing the first volume. The work which it represents was concerned entirely with the study of spontaneous and inoculated tumors in mice, and seems to have been wholly performed by Dr. Ernest E. Tyzzer. A hopeful view is taken of the possible beneficent results of the study of such growths. We have not space for an analysis of Dr. Tyzzer's papers; it is rather our present purpose to mention certain remarks that are to be found in the introductory section, written by Dr. J. Collins Warren.

Dr. Warren tells us that early in their investigation the commission recognized the importance of proceeding from an aetiological point of view, but do not wish to be regarded as underrating that of the study of the disease from the clinical standpoint. But, he says, "to carry on clinical investigations on a scale which would bring out new and valuable data would require resources far beyond what most commissions have at their disposal." Large endowments, he adds, would enable investigators to "place the clinical and the laboratory work in close juxtaposition in such a way as to produce results which it is not possible to obtain either at the hospitals or with the material of private practice which practitioners of the present day have at their disposal;" and he alludes to the large expenditure of money

which would be entailed by special wards for the study of cancer.

We have in New York two hospitals for the treatment of cancer, in one of which diseases of the skin also are treated. Something tangible has been accomplished in each of them in the way of adding to our knowledge of malignant disease, but, since they exist for the prime object of aiding sufferers from cancer—as many of them as possible and with the least practicable expenditure of time—it can readily be understood that for purposes of investigation they must fall short of the facilities which Dr. Warren has in mind. The disease should be studied, he says, "not only in its incurable stages, but at its very inception, when it is most susceptible to the action of remedial measures." But the incurable cases should not be neglected. There may be means of inducing persons with incipient cancer to seek for hospital relief in greater numbers than at present; certainly it would not be denied them. The hospitals must do the best they can for the greatest number of those who have any apparent prospect of cure or amelioration, and that duty necessarily restricts the number of advanced cases that can be kept under observation. The study of advanced cases may not be so useful as that of incipient examples, but doubtless it is of importance, and it could be pursued in an avowed research hospital more properly than in one designed solely for therapeutic purposes, and in conjunction with laboratory work.

Such an institution, of course, would involve great expense, and its funds would have to be supplied rather by persons looking for ultimate results than by those interested only in the present benefit of cancer victims. According to Dr. Warren, the Croft Commission feel that "the investigation of cancer has now reached a point where it is possible to take a new departure in this (the clinical) direction on a far more extended scale than has ever been attempted and on lines even broader than those which have been laid down for the study and control of tuberculosis." It is but human to entertain the idea that one's own efforts for the welfare of humanity are not meeting with their fair measure of support, and therefore we cannot wonder that Dr. Warren says "A moderate portion of the vast sums of money which are being used in the crusade against tuberculosis would be of the greatest value at the present moment in the attack upon perhaps the next most dreaded disease of modern times." Without entering upon a consideration of the comparative importance of tuberculosis and malignant disease as regards the need of investigation, we heartily express the hope that there may be forth-

coming all the funds required for an adequate clinical study of cancer.

## VIVISECTION IN THE STATE OF NEW YORK.

A number of our professional brethren seem to have misapprehended in some respects the article on this subject which we published in last week's issue. It will be remembered that we commended a certain bill entitled An Act to Prevent Cruelty by Regulating Experiments on Living Animals, soon to be introduced into the legislature of the State of New York. Those of our friends to whom we now have reference fear that the bill will be so changed before its actual introduction or so amended afterward that it will no longer merit whatever approval it may now meet with at the hands of the medical profession. Of course such changes are quite possible, and we had no idea of giving our support in advance to unknown alterations. What we said was with this understanding, not necessarily expressed.

Others of our friends, while under no misunderstanding as to our view, dissent from it, and we must acknowledge that their attitude is founded on reasons which are too cogent to be overlooked. They say that the bill is speciously drawn and really intended only as an entering wedge to open the way for more drastic and inquisitorial legislation. In particular, they object to Section 2, relating to reports required to be made of experiments, pointing out that such reports will furnish *ad captandum* material with which fanatics may in the future incite in the public mind a ruthless opposition to all forms of experiments on animals, as a consequence of which we shall be reduced to the comparative impotence which for several years now has hampered our colleagues in England. It may well be that they are right. On the supposition that they are, we must withdraw our support of the bill and simply advise our readers to await developments and the close discussion that the matter is likely to draw out.

When the bill was brought to our attention there was shown to us an endorsement of it bearing the signatures of a number of medical men of renown in the profession. On the strength of those signatures we felt that we could not but support a bill that could command them. It has come to our knowledge now (since our article was published) that these gentlemen have revised their opinion and withdrawn their commendation of the bill. Mindful of the old saying, *l'homme coupable, c'est celui qui ne change jamais*, they have not hesitated to renounce a stand of which they have recognized the untenability. We cannot, therefore, longer base

an opinion, even in part, on their first judgment; consequently we must withdraw our support of the bill. Indeed, we are now convinced that no legislation on the subject is called for, since the law as it stands is quite sufficient for the punishment of persons guilty of cruelty to animals.

## TWO GREAT SURGEONS OF EDINBURGH.

Within a little more than a fortnight past the people of Edinburgh have had to join with the medical profession of their town, renowned in medicine—and, we may truly add, with our profession throughout the world—in mourning the death of two of their great surgeons, Mr. Thomas Annandale and Sir Patrick Heron Watson, who, to their great credit, were commonly known respectively as "Tommy" Annandale and "Pat" Watson. We do not speak thus familiarly of men of exalted position save as in terms of endearment. Edinburgh, like Philadelphia and all our southern cities, knows its medical men and honors and loves them, while such seething and reckless communities as that of New York take little, if any, note of personalities that are not intimately associated with great commercial, political, or military doings.

Professor Annandale, English by birth, but genuinely Scotch by education and in the activities of his career, was an operator of exceptional skill and boldness and a diagnostician of almost intuitive perception. He was a man of lively sympathy, always in close touch with whatever movements made for the interests of the institutions that commanded his support, helpful to his students, and gracious and cheery with the sick, whether their condition was exalted or of the humblest. It is no wonder, then, that all Edinburgh mourns for him. His end was sudden; he was found dead in bed after a day of protracted work and an evening spent largely in making telephonic arrangements for the following day's duties. He died during the night of December 19th-20th, at the age of sixty-nine.

Sir Patrick, whose life lasted a few years longer—he was born in 1832—was of equal professional renown, though for a considerable period preceding his death he was unable, by reason of failing health, to take an active part in professional work. He died on December 21st, of angina pectoris. During much of his early professional career he was in military life. He served with distinction as a medical officer in the Crimean war. For many years past his name has been of frequent appearance in the periodical medical literature of Great Britain. He was knighted in 1903. He is described as of courtly manners and a military bearing, "an authority in the *science* [sic] of royal etiquette," says the *Scotsman*, but at the same time "a genial com-

panion and not without a touch of humor in his conversation."

Though not so much resorted to now by students from various parts of the world as she was a hundred years ago, "Auld Reekie" has by no means ceased to implant sound knowledge of medicine in those who still turn to her as a source of learning. And so she will continue. She has lost many a learned and brilliant exponent of our art in the past, but the ranks are always replenished.

#### ANAPHYLAXIS AND ANAPHYLAXINES.

One of the most striking and important developments of bacteriological science has been the keen stimulus felt in the search for fundamental facts concerning poisons in general and certain organic, poisonous substances in particular. Of recent years, C. Richet, of Paris, has found in actinians and mussels certain substances showing peculiar poisonous reactions, to a mixture of which he has given the name of mytilocongestine. In studying the properties of this substance he has been impressed with certain peculiar affinities which it seems to possess with some bacterial toxins, and he has been led to a review of the problem of immunity seen in the light of a new type of poisoning which he describes.

In a comparatively recent study (*Annales de l'Institut Pasteur*, July) he writes that poisons may be divided into two main groups—the members of the one killing immediately or very rapidly, as chloroform paralyzes circulatory structures, strychnine destroys nervous structures, curare acts on neuromuscular terminal organs, mercury destroys cellular metabolism, etc., while those of another group kill, as it were, at a long distance, perhaps after several weeks, and by a mechanism which seems different from any other which has heretofore been observed. These poisons are not immediately operative, but they provoke within the body the formation of toxic substances of a sort which, after injection of the poison, develop a true disease. Or, stated in another way, the disease—i. e., the ensemble of morbid phenomena which results from a microbe infection, is a slow intoxication. It is doubly slow; in the first place, because the poison produced by the microbe is slowly and progressively secreted, so far as, and in the same manner as, the microbe proliferates, and, further, because this poison itself acts slowly.

Richet calls attention to the fact that the substances extracted from actinians, from sponges, and from mussels have this character of being able to develop a special morbid state, with an evolution resembling that of a disease. If one injects this substance in large doses into the venous system of

an animal (a rabbit or a dog), it will die in from four to five days; the injection of doses one fifth as great, however, brings about a chronic action which persists from twenty to thirty days at least. The contrast between the action of this type of poison and that of the ordinary crystalloid poison is very striking, for, as is well known, in the latter class, strychnine being taken as an example, amounts of one fifth that of a lethal dose either cause only nominal symptoms or are innocuous. On the other hand, Richet's mytilocongestine in amounts of one fifth of the lethal dose causes a grave form of chronic intoxication, which frequently persists for thirty days.

During this period of chronic poisoning, which Richet has termed anaphylaxis, the body is more highly sensitive to the action of the poison than it was before the poisoning. With mytilocongestine, the sensibility of the body in the greater number of cases is rendered five times as great, in some instances the sensibility being enhanced at least twenty-five fold. Richet thinks that the presence of a toxogenic substance is the cause of this increase in the toxicity of mytilocongestine. *In vitro*, the mixture of mytilocongestine with the anaphylactic serum of dogs is more toxic than this same poison when in watery solution, and the serum of an anaphylactic dog, when injected into a normal dog, can produce anaphylaxis.

Anaphylaxis, then, he argues, is due to the presence of a sensitizing substance (toxogenine) which, by reaction with mytilocongestine, develops a poison which acts immediately. Anaphylaxis is established only after a certain length of time, and persists for about forty days in the animals used by the experimenters, for, after this length of time, the animals become relatively immune, so that injections of large doses of poison are not followed by symptoms of poisoning.

The general relations of anaphylaxis to immunity, as postulated by the author, are highly suggestive. He considers anaphylaxis as a preliminary stage to immunity, rendering the latter possible, for animals react to the injection of toxic substances of the nature of toxalbumins by producing sensibilizing substances, or toxogenines, which create an anaphylactic state, and at the same time that this state is engendered antitoxines are formed, but much more slowly. When, in five or six weeks, the toxogenines disappear, the antitoxines persist. Anaphylaxis is a sort of rapid defense for small doses, permitting the organism to rise vigorously to feeble doses of poison secreted by microorganisms, and thus to defend the organism so long as the attack is not an energetic one. It is a precursor of immunity and one of the factors which make it possible.

### Obituary.

NICHOLAS SENN, M. D.,  
of Chicago.

This great surgeon died on Thursday, January 2d, after an illness of several weeks' duration in its acute stage, from a cardiac affection supposed to have been aggravated by his recent mountain experiences in South America. He was sixty-three years old. Dr. Senn was born in Switzerland, but was brought to this country when he was a very young child. The family settled in Wisconsin, on a farm. With only the advantages of the local schools for

NICHOLAS SENN, M. D.

a preliminary education, and doing out his resources by teaching school, he went through the course in the Chicago Medical College, where he took his medical degree in 1868. He served a term on the house staff of the Cook County Hospital and then settled in practice in Fond du Lac. He subsequently practised for twenty years in Milwaukee, where he made a national reputation as a surgeon. Then he moved to Chicago and was made professor of surgery in the College of Physicians and Surgeons of that city, and subsequently in the Rush Medical College. Early in his career he evinced an aptitude for military service, and his services in the National Guard of Wisconsin, in that of Illinois, and in the army during the war with Spain won distinction for him.

It was not only as an operating surgeon that Dr. Senn was distinguished; he was the author of many important additions to our literature. He was of a frank and martial mien, and his personality made him liked as well as esteemed in the profession. In

the later years of his life he was able to indulge his fondness for travel, but in his journeyings he always kept professional matters in mind and gave his impressions vividly in contributions to the journals.

ROBERT WILLIAM TAYLOR, M. D.,  
of New York.

Dr. Taylor died after a brief illness on Sunday, January 5th, at the age of sixty-five years. He was born in England and brought up in New Jersey, but came to New York when he was a young man. Like many other eminent physicians, he began life as a pharmacist. He studied medicine under the direction of the late Professor Willard Parker, and was graduated from the College of Physicians and Surgeons in the class of 1868. For a number of years he was professor of venereal diseases in that institution, and at the time of his death he was consulting genitourinary surgeon to Bellevue and the City hospitals and consulting surgeon to the French Hospital.

At the outset of his medical career he was in general practice for a few years, but even then his attention was chiefly devoted to skin and venereal diseases, in which he soon achieved distinction. So

ROBERT WILLIAM TAYLOR, M. D.

early as in 1871, only three years after his graduation, his classic essay on Dactylitis Syphilitica was published in the *American Journal of Syphilology and Dermatology*, and it at once established his reputation as an acute clinical observer and as a critic of the writings of others. His contributions to our literature thereafter were numerous and weighty, both in the form of journal articles and in that of books. His published representative work all

ways cogent, and his style of writing was exceptionally attractive. In verbal debate, too, he was remarkably forcible. As a diagnostician in skin and venereal diseases there was not his superior in the world, and as a therapist he was unusually successful.

Dr. Taylor had many close friends, and not a few will be grieved to learn of his death. No warmer heart than his ever beat in a human breast; he was the embodiment of loyalty, and no trouble was too great for him to take in furtherance of a worthy cause or in imparting hope to an afflicted friend. In his death the profession has met with a loss of the first magnitude.

ALBERT HOFFA, M. D.,

Of Berlin, Germany.

While only of middle age, Professor Hoffa has been cut off in his successful career. Born in Richmond, Cape of Good Hope, on March 31, 1859, he studied medicine at the universities of Marburg and Freiburg, and was graduated in 1883. In the same year he became assistant at the Julius Hospital in Würzburg, and three years later he was admitted to the medical faculty of the university at Würzburg as *Privatdozent* in surgery, and in 1897 was appointed assistant professor. In 1902 he was called to Berlin as professor of orthopaedic surgery and chief physician of that department at the university dispensary, which position he held at his death. From 1886 till 1902 he had a private hospital for orthopaedic patients in Würzburg.

Hoffa at the beginning of his career paid special attention to bacteriology, and his researches in anthrax should be mentioned (*Die Natur des Milzbrandgiftes*, Wiesbaden, 1886), but soon entered the field of surgery, where he became the founder of modern orthopaedics in Germany. It was Hoffa who explored the theory and treatment of scoliosis and congenital hip luxation and deformities, designing and very often making himself apparatus for his patients, following and adding to the theories of Hesselig. Later he directed his attention to the influence of nervous diseases upon orthopaedic pathology, and to the treatment of joint diseases, especially the pathology of the knee joint.

During his visit to the United States, in 1904, the Jefferson Medical College conferred an honorary degree upon Professor Hoffa.

### News Items.

**Changes of Address.**—Dr. William H. Mackinney, to 1831 Chestnut street, Philadelphia.

**College of Physicians and Surgeons, New York.**—Dr. George Thomas Jackson has been appointed professor of dermatology to succeed Dr. George Henry Fox, who has resigned.

**The Hospital Saturday and Sunday Association of St. Louis.**—The total collections of this association for the year 1904 were \$7,841.15, against \$7,850.11 less than the amount collected in 1903.

**The Society of Medical Jurisprudence, New York.**—The two hundred and tenth regular meeting of this society will be held at the New York Academy of Medicine on Monday evening, January 13th, at eight o'clock.

**Syracuse, N. Y., Academy of Medicine.**—A meeting of this academy was held on January 7th. The retiring president, Dr. A. B. Miller, delivered an address, and Dr. F. C. Curtis, of Albany, read a paper on Smallpox and Diseases Confounded with It.

**Food Inspection in New Jersey.**—During the month ending December 31, 1907, 171 specimens of foodstuffs were examined under the direction of the State Board of Health in the State Laboratory of Hygiene, 21 of which were found to be below standard.

**Richmond County, N. Y., Medical Society.**—The regular monthly meeting was held at the Staten Island Academy of Medicine on Wednesday evening, January 8th. The paper of the evening was read by Dr. W. T. Jenkins on Disinfection as a Preventive of Dissemination of Smallpox.

**The Jefferson County, Ky., Medical Society** held its annual meeting on December 23d in Louisville and elected the following officers: President, Dr. Benjamin F. Zimmerman; vice presidents, Dr. Charles W. Hibbitt and Dr. J. Rowan Morrison; secretary, Dr. Virgil E. Simpson; treasurer, Dr. John J. Moren.

**The Northwestern Medical Society, Philadelphia,** held a meeting on January 6th, when the following papers were read: Lobar Pneumonia Complicated by Pulmonary Hemorrhage; Cancer of the Uterus Treated by Electrothermic Hemostasis, by Dr. A. J. Downes; Dilatation of the Parturient Cervix, by Dr. John Cook Hirst.

**Two of Scotland's Leading Surgeons Dead.**—Professor Thomas Annandale, regius professor of surgery in the University of Edinburgh, died suddenly of heart disease on December 20th, aged sixty-nine years, and on December 21st Sir Patrick Heron Watson died, also from heart disease, at the age of seventy-five years.

**New York Academy of Medicine.**—A stated meeting of the academy will be held on Thursday, January 16th, at 8:30 p. m. Dr. Beverley Robinson will read a paper on Laryngeal Phthisis, and there will be additional contributions on the subject by Dr. Joseph Gleitsmann, Dr. A. Jacobi, Dr. Walter Chappel, Dr. S. A. Knopf, and Dr. R. C. Myles.

**Floyd County, Ga., Medical Society.**—At the annual meeting of this society, which was held recently, the following officers were elected for the ensuing year: President, Dr. J. C. Watts, of Rome; vice president, Dr. Isaac Sewell, of Cave Spring; secretary, Dr. W. L. Funkhouser, of Rome, and treasurer, Dr. William De Lay, of Rome.

**Buffalo, N. Y., Academy of Medicine.**—A meeting of the Section in Surgery was held on January 7th. Dr. Bransford Lewis, of St. Louis, Mo., read a paper on Practical Cystoscopy, with a presentation of cystoscopes, examining, catheterizing, and operative, and Dr. David E. Wheeler, of Buffalo, gave an exhibition of lantern slides of skin and genitourinary diseases.

**The Fourth Harvey Lecture.**—As has been previously announced, the fourth lecture in the Harvey Society course will be delivered at the New York Academy of Medicine on Saturday, January 11th, at 8:30 p. m., by Professor Ernest H. Starling, of the University of London. The subject will be The Chemical Control of the Body. All interested are cordially invited to be present.

**Deutsche Medizinische Gesellschaft der Stadt New York.**—A meeting of the German Medical Association of the City of New York was held at the Academy of Medicine on January 6th, when the following papers were read: The Operative Aims in Modern Obstetrics, by Dr. A. Stein; Inhalation Therapeutics, by Dr. F. Ruppert, and the Treatment of Migraine, by Dr. A. Herzfeld.

**Charitable Bequests and Donations.**—By the will of Eliza M. Wray the Philadelphia Home for Incurables receives \$200.

By the will of Mrs. Mary A. Brannon the Carney Hospital, Boston, will receive \$500.

The German Hospital, Brooklyn, has received a check for \$7,500 from the Aid Society of the hospital.

**American Philosophical Society.**—The annual meeting of this society was held on January 3d, and the following officers for the ensuing year were elected: President, Dr. William W. Keen; vice presidents, Mr. George

F. Barker, Mr. William B. Scott, and Mr. Simon Newcomb; secretaries, Dr. I. M. Hays, Mr. Arthur M. Goodspeed, Dr. James Holland, and Mr. Amos P. Brown.

**The Philadelphia Medical Examiners' Association.**—At a meeting of this association, held on January 7th, the evening was devoted to a symposium on the Heart and Life Expectancy. Dr. Robert N. Willson demonstrated the Physical Examination of the Heart; Dr. William E. Hughes spoke on Observations as to Intracardial Lesions, and Dr. Judson Daland described the Recognition of Extracardial Lesions.

**The Elmira, N. Y., Academy of Medicine** held its annual meeting on Wednesday, January 8th, and elected officers for the ensuing year. Dr. H. W. Fudge delivered the presidential address, and papers were read as follows: The Present Status of Opinion Concerning the Etiology of Tuberculosis, by Dr. C. W. M. Brown, and Some Considerations of Systemic Infections Through Diseased Tonsils, by Dr. G. M. Case.

**The Hospital Ship "Relief."**—Dr. Charles F. Stokes, a surgeon in the United States Navy, has received orders directing him to assume command of the hospital ship *Relief*, which is being fitted out at the Navy Yard, Mare Island, Cal., with a full hospital equipment for special duty with the battleship fleet. It was the issuance of this order which led to the controversy which resulted in the resignation of Admiral Brownson.

**Consolidation of Two Louisville Colleges.**—The combination of the Louisville College of Medicine and The Hospital College of Medicine went into effect on January 1st. Dr. L. S. McMurtry is president of the new college; Dr. C. W. Kelly is dean of the faculty, and Dr. W. F. Boggess, associate dean. The institution is known as the Louisville and Hospital Medical College, Medical Department of the Central University of Kentucky.

**The Philadelphia Academy of Surgery.**—At a meeting of this academy, held on January 6th, the following papers were read: Gunshot Wound of the Stomach with Posterior Drainage, by Dr. Edward B. Hodge, Jr.; Report of a Case of Stab Wound of the Diaphragm, by Dr. Francis T. Stewart; Report of a Case of Tuberculosis of the Cæcum, by Dr. John H. Jopson; Renal Diagnosis and Efficiency, by Dr. B. A. Thomas.

**The Medical Society of the County of Ontario, N. Y.**—The quarterly meeting of this society will be held in Canandaigua, on Tuesday, January 14th, when the following papers will be read: A Rare Case of Dermatitis Exfoliativa, by Dr. W. A. Howe; Legal Status of Physicians' Fees, by W. C. Ellis, Esq., of Shortsville, N. Y.; Prostatic Hypertrophy, by Dr. W. B. Jones, of Rochester, N. Y.; Treatment of Lobar Pneumonia, by Dr. C. W. Selover.

**The Pathological Society of Philadelphia.**—At a meeting of this society, held on January 9th, the following papers were read: The Coordination of Gastric and Intestinal Digestion by the Action of the Pyloric Sphincter, by Dr. Walter B. Cannon, of Harvard University; and Bacterial Vaccines of Staphylococcal Strains, by Dr. Harlan Shuemaker. Dr. Judson Daland gave a demonstration of the Strongyloides Intestinalis from a Philadelphian.

**Repairs at Ellis Island.**—A bill has been introduced into Congress providing for an appropriation of \$550,000 for urgent repairs and construction at the immigration station at Ellis Island. The bill suggests that the appropriation come out of the emigrant fund. It provides \$35,000 for refitting the plant, \$125,000 for a steam ferryboat, \$250,000 for completing the wing to the hospital, and \$150,000 for the completion of the contagious disease hospital.

**New York Pathological Society.**—The anniversary meeting of this society was held on January 8th, when the following papers were read: Tuberculosis of the Ductus Thoracicus, by Dr. Richard Weil; Ureteritis Cystica, by Dr. Otto H. Schultze; Diptheritic Laryngitis, Tracheitis, and Bronchitis, by Dr. Thomas Flournoy, and Enteritis Obliterans, by Dr. I. Levin. Officers were elected and committees were appointed for the ensuing year.

**The Western Surgical and Gynecological Association.**—The seventeenth annual meeting of this association was held in St. Louis, Mo., on December 30 and 31, 1907, and officers for the ensuing year were elected as follows: President, Dr. W. W. Keen, of St. Louis, Mo.

presidents, Dr. Willard Barlett, of St. Louis, and Dr. Harry A. Sifton, of Milwaukee; secretary and treasurer, Dr. Arthur T. Mann, of Minneapolis. The next meeting will be held in Minneapolis on December 30 and 31, 1908.

**A Tuberculosis Exhibit in New York.**—The exhibit of the Committee on the Prevention of Tuberculosis of the Charity Organization Society, which was at the Jamestown Exposition, was opened to the public on January 8th, in a building in East Twenty-third street. The exhibit consists of photographs and models of hospitals, sanitariums, day camps, tenement conditions, diet kitchens, sweat shops, etc. Informal talks will be given each noon on the subject of tuberculosis, and stereopticon views will be shown at night.

**College of Physicians of Philadelphia.**—At the regular meeting, held on Wednesday evening, January 1st, officers were elected for the ensuing year as follows: President, Dr. James Tyson; vice president, Dr. G. E. de Schweinitz; secretary, Dr. Thomas R. Neilson; treasurer, Dr. Richard H. Harte; honorary librarian, Dr. Frederick P. Henry. Colonel W. B. Bannerman, of Bombay, India, was elected an associate fellow. The honorary librarian reported an addition of fifty-six volumes to the library during December.

**The Health of Pittsburgh.**—During the week ending December 21, 1907, the following cases of transmissible diseases were reported to the Bureau of Health of Pittsburgh: Chickenpox, 18 cases, 0 deaths; typhoid fever, 103 cases, 17 deaths; scarlet fever, 13 cases, 3 deaths; diphtheria, 20 cases, 5 deaths; measles, 65 cases, 3 deaths; whooping cough, 8 cases, 1 death; pulmonary tuberculosis, 7 cases, 6 deaths. The total deaths for the week numbered 155 in an estimated population of 403,330, corresponding to an annual death rate of 19.98 per 1,000 population.

**A Special Meeting of the Medical Association of the Greater City of New York** was held on Monday, January 6th, under the direction of the chairman for the Borough of the Bronx. Dr. Thomas E. Satterthwaite, president of the association, read a paper entitled Some Phases of Myocardial Disease; Dr. Louis Faugeres Bishop read a paper entitled Instruments of Precision in the Management of Diseases of the Heart; Dr. William H. Porter read a paper on the Diagnosis of Diseases of the Heart, and Dr. Reynold Webb Wilcox delivered an address on the Use of Drugs in Diseases of the Heart. A general discussion followed.

**The Mortality of Chicago.**—According to the report of the department of health for the week ending December 28, 1907, there were during the week 569 deaths, as compared with 575 for the corresponding week in 1906. The annual death rate in 1,000 of population was 14.08. The principal causes of death were: Apoplexy, 8; Bright's disease, 36; bronchitis, 23; consumption, 44; cancer, 30; convulsions, 6; diphtheria, 9; heart diseases, 47; influenza, 6; intestinal diseases, acute, 32; measles, 1; nervous diseases, 23; pneumonia, 103; suicide, 4; scarlet fever, 16; typhoid fever, 7; violence (other than suicide), 28; whooping cough, 3; all other causes, 141.

**Scientific Society Meetings in Philadelphia for the Week Ending January 18, 1908.**—Monday, January 13th, Section in General Medicine, College of Physicians; Wills Hospital Ophthalmic Society. Tuesday, January 14th, Philadelphia Paediatric Society; Botanical Section, Academy of Natural Sciences. Wednesday, January 15th, Philadelphia County Medical Society (Business Meeting open to members only); Section in Otology and Laryngology, College of Physicians; Association of Clinical Assistants of Wills Hospital; Franklin Institute. Thursday, January 16th, Section Meeting, Franklin Institute; Medical Society of the Woman's Hospital. Friday, January 17th, University of Pennsylvania Medical Society; American Philosophical Society.

**The Mortality of New Jersey.**—According to the report of the State Bureau of Vital Statistics for December, 1907, there were 2745 deaths reported in New Jersey during the month ending December 15, 1907, which was 291 less than the monthly average for the past year. There were 155 deaths among infants under one year of age, 100 deaths of children over one year of age and under five years of age, and 84 deaths of persons sixty years of age and over. Pneumonia caused 210 deaths, as compared

47 over the previous month, and there were 30 deaths from typhoid fever, a decrease of 7 from the previous month. Among other important causes of death were the following: Diseases of the nervous system, 352; tuberculosis of the lungs, 270; cancer, 112; diseases of the circulatory system, 318; Bright's disease, 203; infantile diarrhoea, 195. There were 36 deaths from suicide, which was 7 more than the average for the preceding twelve months.

#### Infectious Diseases in New York:

*We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending January 4, 1907:*

	-December 1831-		-January 1, 1907-	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever	121	25	121	25
Scarlet fever	121	25	121	25
Measles	121	25	121	25
Whooping cough	121	25	121	25
Diphtheria	121	25	121	25
Tuberculosis (pulmonary)	121	25	121	25
Cerebrospinal meningitis	121	25	121	25
Total	121	25	121	25

**Southern Medical College Association.**—The annual meeting of this association was held in New Orleans recently. Three medical schools were added to the membership, viz.: the Atlanta College of Physicians and Surgeons, the Medical Department of the University of Kansas, and the College of Physicians and Surgeons of Little Rock, Ark. Officers for the ensuing year were elected as follows: President, Dr. Christopher Tompkins, dean of the Medical College of Virginia; vice president, Dr. W. S. Rogers, dean of the Memphis Hospital and Medical College; secretary and treasurer, Dr. L. C. Morris, of the Birmingham Medical College; chairman of the executive committee, Dr. J. S. Cain, of Sewanee, Tenn.

**A Proposed Hospital for Inebriates.**—At a meeting of the Philadelphia County Medical Society, held on Wednesday, January 8th, the first steps were taken in a movement to secure for the State of Pennsylvania a hospital for the treatment and care of inebriates and persons addicted to the use of drugs. The subject was introduced by Mr. Robert A. Woods, president of the board of trustees of the Foxboro, Mass., Inebriate Hospital, and Dr. John B. Carrell, of Haboro, Pa., read a paper on the Necessity for the Establishment of an Inebriate Hospital for the Care of Alcoholics and Drug Habitués. A number of State senators and representatives were present, and plans were discussed. It is proposed to prepare a bill to be presented to the next legislature, asking for an appropriation to cover the cost of erection and maintenance of such an institution. The object of the meeting was to arouse sentiment and interest the medical profession, as well as the public, in the undertaking.

**Personal.**—Dr. H. Brantley, of Spring Hope, N. C., is registered at the Philadelphia Polyclinic and College of Graduates in Medicine.

Miss Annie M. Rykert has been appointed superintendent of the New York City Graduate Hospital.

Dr. Gordon Wilson, of Baltimore, has been placed in charge of the medical department of the consumptive hospital at Bayview Asylum.

Dr. William Starr, of Washington, D. C., who recently celebrated his one hundredth birthday, has been elected a member of the Confederate Veterans' Association.

Major Charles F. Mason, of the Medical Department of the United States Army, will deliver a series of lectures on First Aid, at the Young Men's Christian Association, Washington, D. C. The first lecture was delivered on Friday, January 10th, and a lecture will be given each Friday, at 8 p. m., until the course is completed.

Dr. John P. Moore, head of the Queens Borough Health Department, has resigned, and will resume his private practice.

**Lectures on Nutrition.**—A course of twelve public lectures on nutrition will be given at the Teachers' College, 120th street and Amsterdam avenue, for the benefit of those who are interested in the problem of food in the home and in institutions. The first lecture will be given on Monday, January 13th, at 4 o'clock, and the other lectures will follow every Monday at the same time and place for twelve weeks. There will be five lectures on digestion and assimilation by Dr. William J. Gies, of the College of Physicians and Surgeons; four lectures on nutritive require-

ments and the selection of food, by Dr. Henry C. Sherman, of the School of Chemistry, and three lectures on the relation of foods in household practice, by Miss Anna Barrows, of the department of domestic science of the Teachers' College. The lectures will be illustrated.

**Newark, N. J., Medical League.**—At the regular meeting of this organization, held on December 9th, Dr. Willy Meyer, of New York, delivered a lecture on Bier's Hyperæmic Treatment. In a preliminary talk, Dr. Meyer dealt with the subject in a general way, and then read two papers, one on Acute Mastitis, representing the acute diseases in which Bier's treatment may be applied, and the second on Chronic Tuberculosis of the Knee, showing the use of Bier's method in chronic diseases. Dr. Meyer exhibited the suction glasses used in acute mastitis, and showed a mask made of celluloid, to be worn over the nose and mouth in tuberculosis of the lungs. After the lecture a dinner was served in honor of Dr. Meyer, after which he illustrated the application of the rubber band and cupping glasses on the arm of a member. At the annual meeting of the league, held on December 23d, the following officers were elected for the ensuing year: President, Dr. David A. Kraker; vice president, Dr. Herbert W. Long; treasurer, Dr. E. Steiner; secretary, Dr. Louis Weiss.

**The Health of Philadelphia.**—During the week ending December 21, 1907, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Typhoid fever, 78 cases, 7 deaths; scarlet fever, 47 cases, 3 deaths; chicken pox, 56 cases, 0 deaths; diphtheria, 106 cases, 10 deaths; cerebrospinal meningitis, 3 cases, 0 deaths; measles, 54 cases, 2 deaths; whooping cough, 13 cases, 2 deaths; pulmonary tuberculosis 75 cases, 50 deaths; pneumonia, 91 cases, 68 deaths; erysipelas, 12 cases, 0 deaths; puerperal fever, 5 cases, 3 deaths; septicaemia, 4 cases, 2 deaths; mumps, 6 cases, 0 deaths; German measles, 2 cases, 0 deaths; cancer, 20 cases, 11 deaths. The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 9; tetanus, 1; diarrhoea and enteritis, under two years of age, 14. The total deaths numbered 499 in an estimated population of 1,500,595, corresponding to an annual death rate of 17.21 in 1,000 population. The total infant mortality was 104; under one year of age, 86; between one and two years of age, 18. There were 36 still births—17 males, and 19 females. The total precipitation was 0.05 inch. The temperatures were rather high for the time of year, a maximum of 47° being recorded on the 21st.

#### Society Meetings for the Coming Week:

**MONDAY, January 13th.**—New York Academy of Medicine (Section in Neurology and Psychiatry); Society of Medical Jurisprudence, New York; New York Ophthalmological Society; Society of Alumni of St. Mary's Hospital, Brooklyn; Corning, N. Y., Medical Association; Waterbury, Conn., Medical Association.

**TUESDAY, January 14th.**—New York Academy of Medicine (Section in Public Health); New York Obstetrical Society; Newburgh Bay Medical Society; Medical Society of the County of Schenectady, N. Y. (annual); Practitioners' Club of Jersey City, N. J.; Medical Society of the County of Rensselaer, N. Y.; Buffalo Academy of Medicine (Section in Medicine).

**WEDNESDAY, January 15th.**—New York Academy of Medicine (Section in Genitourinary Diseases); New York Society of Dermatology and Genitourinary Surgery; Woman's Medical Association of New York City (New York Academy of Medicine); Medicolegal Society, New York; New Jersey Academy of Medicine (Jersey City); Northwestern Medical and Surgical Society of New York; New York Society of Internal Medicine; New Haven, Conn., Medical Association (annual); Buffalo Medical Club.

**THURSDAY, January 16th.**—New York Academy of Medicine; German Medical Society, Brooklyn; Newark, N. J., Medical and Surgical Society; Æsculapian Club of Buffalo, N. Y.

**FRIDAY, January 17th.**—New York Academy of Medicine (Section in Orthopedic Surgery); Clinical Society of the New York Post Graduate Medical School and Hospital; East Side Physicians' Association of the City of New York; New York Microscopical Society; Brooklyn Medical Society.

## Pith of Current Literature.

## THE BOSTON MEDICAL AND SURGICAL JOURNAL.

January 2, 1908.

1. Renal Tuberculosis and Indications for Operation,  
By LINCOLN DAVIS.
2. The Value of Vaccine Therapy to the General Practitioner in the Treatment of Bacterial Diseases,  
By CLEVELAND FLOYD and ARTHUR M. WORTHINGTON.
3. Some Personal Experiences with Specific Vaccines in the Treatment of Bacterial Disease,  
By MARK W. RICHARDSON.
4. Certain Aspects of the Treatment of Infections with Bacterial Vaccines,  
By ROGER J. LEE.
5. Vaccine Therapy: A Report on Sir Almroth E. Wright's London Clinic,  
By HELEN C. PUTNAM.

1. **Renal Tuberculosis.**—Davis says that abundant clinical experience has shown, and particularly that of the last few years, that in properly selected cases nephrectomy gives splendid results in tuberculosis of the kidney. There would be little justification for nephrectomy if it was true that the renal disease was secondary to a primary focus in the bladder, which would remain after the operation to infect the other kidney. Our present knowledge, however, that the kidney is practically always the primary focus, and that the disease secondarily affects the ureter and bladder, not only puts the operation of nephrectomy on a rational basis, but strongly indicates an early operation before the secondary changes in the bladder have become irreparable. In fact, radical removal seems to be the only treatment for this condition, offering hope of permanent cure. Spontaneous healing of tuberculosis of the kidney, unlike tuberculosis in various other organs, appears to be extraordinarily rare, if not unknown. Conclusive cases are lacking in the literature. More light is greatly needed on the subject. It seems to be pretty generally agreed, however, that hygienic measures which are so valuable in treating tuberculosis situated elsewhere in the body, seem less effective in arresting the process when in the kidney. Why this should be so is hard to say. The author quotes Senator, of Berlin, who said: "When renal tuberculosis is not amenable to operative treatment, we know of no other termination than death; at least recovery must be rare." If this is true, remarks Davis, the question presents itself at once in every case, Is operative treatment indicated, and if so, what form of operation is best? Resection of the tuberculous focus is dangerous on account of hæmorrhage, and uncertain as to removal of the entire disease. Nephrotomy is merely a palliative measure, and should be followed by a nephrectomy to obtain a cure, the secondary nephrectomy being as a rule more difficult than a primary one would have been. Complete nephrectomy, with removal of ureter when diseased, is the operation of choice for unilateral tuberculosis of the kidney.

3. **Specific Vaccines in the Treatment of Bacterial Disease.**—Richardson adds fifty more cases to his report published October 3, 1907. He has now 163 routine cases, with thirty-five, or 21.4 per cent., of relapses, as compared with forty inoculated cases, with 2 or 5 per cent. relapse.

## THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

January 4, 1908.

1. Medicine and the University, By WILLIAM H. WELCH.

By A. D. MEWBOURN.
7. The Frequency, Mortality, and Treatment of Placenta Prævia,  
By I. L. HILL.
8. The Effects of Hydrastis and Its Alkaloids on Blood Pressure,  
By WILLIAM WHITTRIDGE WILLIAMS.
9. The United States Pharmacopœia,  
By ROBERT A. HATCHER.
10. Evacuation and Depletion of the Tympanic Cavity as Aids to Drainage in Acute Middle Ear Suppuration,  
By LEROY FRIDENBERG.

7. **The Frequency, Mortality, and Treatment of Placenta Prævia.**—Hill observes that among multiparæ placenta prævia can hardly be called a rare complication. In 1,800 cases, of which 87 per cent. were multiparæ and the average number of pregnancies 4 plus, he has found the ratio to be 1 to 225. The mortality has been understated recently because of too broad generalization on a few highly favorable case reports. There has been very little reduction in the foetal death rate, which is still from 40 to 50 per cent. In the presence of hæmorrhage in the last third of gestation the cervix should immediately be dilated sufficiently to allow of a diagnosis by the finger, and if placenta prævia is present the uterus should be emptied without delay. Tamponade of the cervix and vagina is useful as a preliminary step. The Braxton-Hicks version is effective in controlling hæmorrhage and is the safest procedure for the mother, but it does not give satisfactory results for the child. When the dilatability of the cervix makes us positive that delivery can be effected with little or no tearing of the cervix we may elect rapid delivery by version or forceps, packing the uterus and vagina if there is bleeding after the third stage. In cases presenting long, rigid cervixes, complete prævia and a viable child, if the surroundings are favorable, Cæsarean section should be chosen in the interests of the child. The advance in treatment for placenta prævia has been remarkable in reducing the maternal death rate even though the saving of the patients has not been brought so near to being an exact science as some authors would suggest. It would seem that progress must be directed to decreasing the foetal mortality.

8. **The Effects of Hydrastis and Its Alkaloids on Blood Pressure.**—Williams states that the most constant and conspicuous effect of the intravenous injection of hydrastis is a prompt fall of blood pressure. With small doses the pressure promptly returns to normal, and there may be a slight rise above normal. With larger doses (from 0.07 c.c. to 1 c.c. per kilogramme of body weight) there is only partial recovery from the fall of blood pressure or it may remain low. The pressure phenomena are attributable to depression of the cardiac muscle causing the fall and to stimulation of the vessels causing the rise. Very large doses depress

and paralyze the vagus and vasomotor system; otherwise there is no evidence deduced from the myocardiograms and oncometer that the vasomotor system plays any important rôle in the blood pressure changes. The two principal alkaloids of hydrastis, hydrastin and berberin, cause qualitatively the same blood pressure changes, although berberin is the more active and is responsible for about 85 per cent. of the effect of hydrastis, hydrastin causing the remaining 15 per cent. Hydrastis given by mouth or hypodermically causes no change in the blood pressure, heart rate, or respiration. Hydrastinin—an artificial alkaloid derived from hydrastin—causes a rise of blood pressure above normal, which is usually preceded by a slight fall when injected intravenously. The rise is well sustained and is principally caused by stimulation of the cardiac muscle.

10. **Evacuation and Depletion of the Tympanic Cavity as Aids to Drainage in Acute Middle Ear Suppuration.**—Fridenberg remarks that the conditions for free drainage afforded by the external auditory canal are ideal, and any attempts to improve them are not only illusory but defeat their own ends. Insufficient drainage is never due to conditions in the canal but invariably to the state of affairs in the tympanic cavity, the size, position, or permeability of the opening in the drum, and it stands to reason that these conditions can not be affected by measures which stop short of the middle ear, and in practice, at all events, do not even reach the drum. For there can not be much doubt of the mechanical difficulty, not to say impracticability, of inserting the end of a gauze drain into the paracentesis opening, and yet this is seriously laid down as a step in the drainage method. The drain can, however, be crowded up against the drum, and here it lies, stopping up the paracentesis opening and damming back secretions. Immediately after paracentesis there is a large admixture of blood with the fluid evacuated. This is apt to clot, and if a tampon is used retention is still more apt to occur. This also applies to the sticky secretion which is not only found in the otitis of influenza, but may be present in the more common types. The occlusive drain accomplishes two purposes, but they are not those of drainage and anti-phlogistics alleged for it by its adherents, but rather act as an occlusive bandage and as an infected poultice. Even if this drain is changed three or four times a day, which will require the services of a nurse, there is no guarantee that retention will be avoided. Secretion from the middle ear is often so profuse as to render such a reliance entirely visionary. Syringing is grateful to the patient, keeps the ear clean and free from discharge for some time, and can be entrusted to the patient or to some member of the family after one or two demonstrations. After the acute symptoms have subsided and the secretion has become less profuse and thick, the antiseptic solution may be changed for a slightly astringent one, such as zinc sulphate, 0.5 per cent., or a solution made by adding pulvis antisepticus (N. F.) one drachm to a pint of water. This will prevent swelling of the canal and check any tendency to the formation of granulation tissue

in subacute cases. Eczema of the auricle and external meatus may be caused by irritating secretions, and possibly by repeated syringing, especially with too highly concentrated or too hot solutions. This may be avoided by carefully drying the skin and applying a little zinc oxide ointment after each irrigation.

#### MEDICAL RECORD.

January 4, 1908.

1. Poliomyelitis Anterior as an Epidemic Disease, By HENRY W. BERG.
  2. Bacterial Vaccines and Curative Sera, By CHARLES BOLDUAN.
  3. The Early Diagnosis and Treatment of Pulmonary Tuberculosis, By JOHN H. PRYOR.
  4. Some Points in Medical Education Considered from the Standpoint of the Student, By BENJAMIN MICHAILOVSKY.
  5. The Term "Stauungs-Hyperæmie," By ALFRED REGINALD ALLEN.
1. **Poliomyelitis Anterior as an Epidemic Disease.**—See abstract on page 42.
2. **Bacterial Vaccines and Curative Sera.**—See abstract on page 41.

4. **Some Points in Medical Education Considered from the Standpoint of the Student.**—Michailovsky remarks that the present improved methods of medical teaching fall very far short of the possible achievements that might be obtained for two great reasons. In the first place, the student body is but indifferently prepared for the reception and use of new knowledge; the remedy, of course, lies in more purposeful teaching in the academic courses. In the second place, those who are to make use of the means and methods of instruction are not sufficiently conversant with the general fundamental principles of pedagogics; the remedy for this lies in individual recognition of the fact and attempts to correct it, or in the establishment of special educational courses in the universities, of which the medical college may be a part, and elsewhere. In addition, the general arrangement of the medical course ought to be so modified as to allow the greatest possible opportunities for correlating and harmonizing the various branches of instruction, thus assisting in the final end and aim of the work, the adequate preparation of young men in the art and science of medicine.

**The Term Stauungs-Hyperæmie.**—Allen remarks that since the advent of Bier's treatment, the English speaking scientific world has been casting about in search of a concise descriptive term in its own tongue, with but questionable success. We find a number of adjectives used to qualify this hyperæmia, such as obstructive, artificial, passive, congestive, and venous, as also the noun, stasis hyperæmia. These terms are all open to the same criticism in that they fail to give a mental picture of the mechanics of Stauungs-Hyperæmie; stasis hyperæmia, besides, conveys a scientifically wrong impression. To the philologist there is nothing more apparent than the fact that where one language possesses a single word descriptive of a condition or thing, another language, in order fully to convey the same idea, may have to use a phrase or a whole sentence. The Germans at times apparently avoid this by forming a colossal word by the agglu-

tinuation of several components. The condition present in the partial obstruction of venous outflow with a retained arterial ingress, the amount of blood thereby being increased in the part, but the circulation thereof never ceasing, is perfectly expressed by the German term *Stauungs-Hyperämie*, and but inadequately or falsely expressed by the use of any two word combination in the English language that he has observed so far in literature. He thinks for this reason it were well to take over bodily this term into our language rather than use any of the English terms which but ill portray what we desire to express.

2. Has a Purin Free Dietary Any Special Therapeutical Value? By C. Watson.
3. A Case of Cerebral Tumor Associated with Subjective Sensations of Smell, By H. C. Thomson.
4. Medical Practitioners and Public Health, By T. Fowler.
5. A Plea for the Study of Bacteriology by the General Practitioner, By J. A. Jones.
6. Cremation, By J. W. Riley.
7. Protection of India from Invasion by Plague, By J. A. Thompson.
8. Primary Sarcoma of the Vermiform Appendix, By T. Carwardine.
9. A Case of Septicæmia with Interesting Reactions to Treatment and Recovery, By C. F. Fothergill.
10. The Post Mortem Statistics of Middle Ear Disease in Young Children, By J. Miller.
11. Observations on Blood Films with Special Reference to the Presence of Hæmoglobin, By F. Porter.

1. **Tuberculosis in Childhood.**—McCaw formulates the following rules to protect children from the ravages of tuberculosis: 1. The notification of all births within twenty-four hours. This would enable health inspectors to examine into the state of the child's surroundings; to have the child removed, or precautions taken, should any case of tuberculosis exist in the house, and to give suitable directions for the care of the child and especially to encourage breast feeding. 2. Complete control of the milk supply by the State. This should include the application of the tuberculin test to dairy cattle, and the removal of all such as react to this test; cleanliness in the collection of all milk, and in the transmission of it from the dairy to the consumer; the removal of all dairies from the centre of large towns and cities. 3. Medical inspection of school children and school premises. First, to detect and remove children who are actually ill or unfit to attend school; and, secondly, to ensure proper ventilation and sanitary arrangements in the schools, and to prevent over crowding. The elementary principles of hygiene should be taught to even young children; to older children the principles of domestic hygiene and economy should be added. 4. Housing reform. Dwelling houses in the poorer districts should be made more sanitary, especially with regard to the free access to them of sunlight and fresh air. A leveling up of the social and domestic conditions of the poor is urgently required, for of the 1,200,000 children born each year in Great Britain, fully one fourth to one third of them are born to want and squalor. 5. Segregation of advanced cases. All advanced cases of phthisis

should be segregated as far as possible and treated in special institutions set apart for that purpose. Children who are allowed to live in the house with a consumptive are exposed to serious risk. 6. Notification of the disease should be compulsory. By this means health officers would know where the disease existed, and it would enable them to take suitable precautions against the spread of the disease, by disinfection and other means. The large proportion of tuberculosis in children comes within the purview of the surgeon to whom the treatment may be safely left. Our increased knowledge regarding the opsonic index has brought treatment with tuberculin within the realm of safe therapeutics, and the clinical success which has attended the employment of this treatment has firmly established its position as a remedial agent of the first importance.

2. **Purin Free Dietary.**—Watson has studied the question as to whether a diet, free of purins, has any special therapeutical value. Purins are substances constructed on the base  $C_5N_4$ . Those of chief clinical importance are uric acid, xanthin, hypoxanthin, adenin, and guanin. The pathology of purins centres largely around gout and gouty disorders, that disease being now generally regarded as a disorder of intermediary purin metabolism. Many authorities attach special value to the administration of a purin free diet, but the writer has come to the conclusion, from practical experience, that such a diet has no special therapeutical effect. The benefit that is derived from such a régime in certain cases would be equally attained by the use of a carefully planned system of feeding framed without special reference to purin contents. In some cases the restriction in amount of animal protein food is of special value, in others the diminution in the carbohydrate, and especially the sugars, is equally efficacious, and in others the restriction of various alcoholic liquors will suffice. Very often complete relief from gouty symptoms follows measures directed to increase the functional activity of the liver, kidneys, skin, or thyroid gland.

9. **Septicæmia.**—Fothergill reports a case of septicæmia showing the following interesting features: 1. The extreme virulence of the infection. 2. The general symptoms became progressively worse until the use of antistreptococcal serum, which almost at once acted beneficially. 3. Brandy was, without doubt, of great benefit in two syncopal attacks, but when the patient was given brandy every four hours it was found to raise both temperature and pulse, and made him more restless, and was, therefore, discontinued. 4. That although the temperature and pulse had been normal or subnormal for nineteen days after the abatement of the general symptoms, yet, when the amputated finger was examined, it was found that not only had all the cartilages of the interphalangeal joints been eroded, but the bone was also eroded into the cancellous tissue, thus proving that temperature and pulse in such a case are no guide to active disease, but that the presence of continuous pain is far more important. 5. The citric acid mixture proved wonderfully efficacious in lowering the abnormally high coagulability of the blood, and seemed directly re-

sponsible for improving the character of the pus and bringing about the rapid and thorough recovery of the wound.

**11. Hæmoconia.**—Porter has studied hæmoconia, those small micrococcal bodies seen in the blood, clear and highly refractile, and with the power of very rapid movement. They are never at rest and appear to have the power of endless motion—a swift tremulous movement, scintillating like heat rays. From his observations he has concluded: 1. Hæmoconia are present in all human blood. 2. Cremated corpuscles and shadow corpuscles are degenerated cells. 3. A certain proportion, if not all, of microcytes are degenerated cells. 4. Blood plates are debris of red and white corpuscles. 5. Leucocytes. Eosinophiles degenerate first; secondly, the polymorphs and lymphocytes are the longest lived (and youngest) of the white cells. 6. Hæmoconia. Some are escaped nuclei of leucocytes, some escaped granules of leucocytes, others are the result of disintegration or alteration of red corpuscles, and all are produced by some change in the blood constituents.

LANCET.

December 21, 1907.

1. Some Experiences of Intracranial Surgery,  
By C. A. BALLANCE.
2. A Note on Gastric Echymosis, Gastrostaxis, and Simple Gastric Ulcer; Their Possible Relations to Hæmorrhagins and Mucolysins,  
By E. C. HORT.

By B. G. A. MOYNIHAN and F. C. MOORE.
5. The Tuberculin Ophthalmoreaction of Calmette,  
By J. W. H. EYRE, B. H. WEDD, and A. F. HERTZ.
6. Notes on a Case of Bone Abscess Caused by an "Intermediate" Bacillus Allied to *Bacillus Paratyphosus*,  
By F. G. BUSHNELL.
7. The After Treatment of Cases of Suprapubic Cystotomy; a New and Economical Method,  
By H. IRVING.
8. A Case of Poisoning by Potassium Bichromate,  
By A. M. GOSSAGE and J. M. BERNSTEIN.

**1. Intracranial Surgery.**—Ballance states that the more common conditions calling for intracranial intervention are: 1. Diseased or displaced bone. These should be dealt with before intradural mischief has arisen. 2. Effused blood. The rapid effusion of blood into the brain from rupture of a diseased bloodvessel has not yet been arrested by an intracranial operation, nor does such an operation seem particularly feasible. But lumbar puncture would probably, by relieving intracranial pressure, be useful in some cases of apoplexy. The necessity for surgical intervention in extradural hæmorrhage following blows on the head has, however, long been recognized. 3. Meningeal inflammation. This takes three forms: (a) Meningitis serosa, an accumulation of fluid, acutely or subacutely, in the subdural space, the subarachnoid space, and in the ventricles. The intracranial serous membranes are excited to hypersecretion by toxins brought to them by the blood or from a neighboring infective focus. The symptoms are fever, a slow pulse, vomiting and drowsiness. Only two methods of treatment have been successful, intradural drainage and ligature of both carotids. (b) Local meningeal suppurations as a result of bone disease, and as a localization of posterior

basal meningitis. In the latter the best operation is one which provides a free bilateral opening and allows the escape of pus from the subarachnoid space. (c) Tuberculous meningitis. Exposure of the disease and drainage of the exudation probably would modify the evolution of the process, just as in tuberculous of the peritonæum, but how is not clear. 4. Abscess of the brain should be treated as abscess elsewhere. 5. Epileptiform neuralgia of the fifth nerve. Intracranial division of the second and third divisions of the fifth nerve is the operation of choice. The foramen rotundum and foramen ovale must be closed either with rubber or with gold leaf, and if the pain returns search must be made for undivided filaments of the nerve. 6. Tumor of the brain. The presence of an intracranial tumor is to be inferred from the following symptoms: (a) Evidences of disturbance of the normal harmonious and correlated functional activity of the various parts of the brain, such as change of disposition or impairment of mental power. (b) Symptoms of increased intracranial pressure—headache, vomiting, optic neuritis, slow pulse and torpor. (c) Symptoms due to irritation or paralysis of particular nerve centres, or groups of nerve centres, the so called focal symptoms, such as paralysis and disturbances of sensation. Diagnosis and localization are sometimes assisted by x ray photography.

**2. Gastric Hæmorrhage and Ulcer.**—Hort epitomizes as follows the various views as to the pathogeny and relations of gastric echymosis, gastrostaxis, and gastric ulcer: 1. Gastric echymosis and gastrostaxis are in no way related to each other or to gastric ulcer. 2. The causes of echymosis and gastrostaxis are most obscure. 3. Gastric ulcer is due to a breakdown of the normal immunity of the mucosa against autodigestion. The writer, on the other hand, tries to show (1) that some forms of gastric echymosis, gastrostaxis, and gastric ulcer are but local expressions of a general blood disease hitherto unrecognized; (2) that echymosis may be intimately associated with gastrostaxis, and both with ulcer; (3) that as a symptom of an unnamed general blood dyscrasia ulcer may also occur without preceding echymosis or gastrostaxis; (4) that (a) echymosis and gastrostaxis are due to the presence in the blood of endotheliolytic and mucolytic bodies, and (b) gastric ulcer itself is due to the presence in the blood of floating hæmorrhagins, mucolysins, and other cytolytics, affecting gastric mucosa through one of two channels—either from lymph stream constantly flooding epithelial cells with the specific toxins (mucolysins) or from escaped blood charged with the same bodies (hæmorrhagins, mucolysins). No other theory as yet put forward brings into line such apparently incongruous manifestations as ulcer without hæmorrhage, hæmorrhage without ulcer, perforation without hæmorrhage, etc. No conclusive evidence as to the cause and effect of ulcer and hæmorrhage can be found post mortem. The present day medical treatment of these conditions must be modified, and the use of surgery in combating a profound toxæmia must be carefully restricted. The evidence submitted by the writer in support of his views is of two kinds: 1. Direct evidence of

cytolysis in man in these forms of capillary hæmorrhage into and from gastric mucosa and of ulceration afforded by (a) blood examinations, and (b) the remarkable results of treatment by serum and by vaccines undertaken with the object of producing immunity in such cases against the specific toxins. 2. Collateral evidence of (a) cytolysis in man in other diseases characterized by gastrostaxis or other hæmorrhagic fluxes or other signs of cytolysis, such as hæmolysis afforded by (1) blood examinations, and (2) the encouraging results of serum and vaccine therapy; and (b) cytolysis in the animal kingdom afforded by (1) the artificial production of cytolytic phenomena in certain animals and (2) the establishment of immunity in such animals by the preparation of sera and vaccines.

1. What Dangers to the Eye Are Present in the Ophthalmoreaction? By F. DE LAPPERSONNE.
2. Tubercules and Vaccines of Carl Spengler. Principles of His Method. By ANDRÉ BERGERON.
3. Medical Treatment of Ulcer of the Stomach. By P. D.
4. The Penial Bone and Partial Ossification of the Penis. By R. ROMME.

1. **Dangers to the Eye in the Ophthalmoreaction.**—De Lapersonne concludes that the ophthalmoreaction is not of itself a source of danger to the eye and that the rare cases in which accidents have occurred simply call for some counsels of prudence. He says that the test should never be made until after a thorough examination has been made of the eye of the patient. In ophthalmology he thinks its use will be very limited. It will not serve for the diagnosis of superficial or deep lesions of the eyeball, but it may for the diagnosis of diseases of the lids, lachrymal passages, and orbits. He does not think it should be used in old patients.

4. **Partial Ossification of the Penis.**—Romme reviews at length the case recently reported by Frangenheim.

December 11, 1907.

1. Examination of Some Stomachs with the Aid of the Röntgen Rays. By TH. TUFFIER and PAUL AUBOURG.
2. Dechloruration in the Treatment of Bright's Disease. By A. MARTINET.

1. **Examination of Stomachs with Röntgen Rays.**—Tuffier and Aubourg present plates showing the conditions found in the stomach of a cadaver, the normal stomach during digestion, stenosis of the pylorus, neoplastic infiltration of the stomach, gastroanastomosis for stenosis of the pylorus, at the beginning of digestion and at the end of the same, the stomach of a dog on which gastroanastomosis had been performed, and a bilocular stomach.

1. The Treatment of Metritis by the Application of Cupping Glasses to the Neck of the Uterus, the Method of Bier. By F. JAYLE and ROBERT LOEY.
2. Acute Suppurative Peritonitis. By ARMAND BERNARD.
3. The Action of the Sphincter of the Pylorus. By R. ROMME.

1. **The Treatment of Metritis by the Method of Bier.**—Jayle and Loevy have devised an apparatus by means of which it is possible to apply suction to the neck of the uterus and they report seven cases of various forms of metritis satisfactorily treated in this manner. Their conclusions are:

The application of cups to the cervix uteri results in the evacuation of the contents, mucus or pus, of the cervical cavity and causes a hyperæmia of the neck. If ulcerations are present the hyperæmia produces a bloody exudation, usually not very abundant. In some cases in which there are little thin walled cysts the aspiration causes the rupture of the latter. 2. After several séances the congestion in the pelvis becomes lessened, while the symptoms of metritis, perimetritis, of inflammation of the annexæ and of pelvic peritonitis slowly become ameliorated. Ulcerations cicatrize and sometimes disappear entirely, while one may easily follow the progress of the epithelization. 3. The aspirations are almost always painful. 4. The application of cups to the neck of the uterus is a new means in gynæcological therapeutics which can be used easily and gives good satisfaction.

  2. Feeding with Ferruginous Cows' Milk. By SCHNÜTGEN.
  3. Concerning the Electric Response to the Galvanic Current in Children with Tetany. By P. PHILIPPSON.
  4. Concerning the Ophthalmoreaction to Tuberculin. By S. COHN.
  5. The Forensic Value and the Knowledge of the Joining of the Complements. By C. BRUCK.
  6. Cold Abscess of the Larynx. By A. ROSENBERG.
  7. Operative Treatment of Traumatic Meningitis. By A. SCHLESINGER.
  8. Concerning the Anatomical Grounds of Weakness of the Heart. By BEITZKE.
2. **Feeding with Ferruginous Cows' Milk.**—Schnütgen uses milk from cows which are fed so as to make their milk ferruginous, not from the addition of an artificial chemical preparation of iron, but by a natural product produced through assimilation in the bodies of the animals. He reports nine cases of anæmia from different cases which were benefited by the use of such ferruginous milk. All of the patients were very sick and all improved remarkably under the treatment.

3. **Response to the Galvanic Current in Children with Tetany.**—Philippson says that in children with tetany there is a distinct local lowering of the electric excitability after from eight to ten minutes of constant galvanization. This lowered action of the current appears to precede a brief phase of increase of excitability with the associated degeneration form of cathode contraction.

4. **The Ophthalmoreaction to Tuberculin.**—Cohn thus sums up his conclusions: 1. The positive appearance of the ophthalmoreaction after use of a 1 per cent. solution of tuberculin indicates tuberculosis with very great probability. 2. A negative reaction does not prove the absence of tuberculosis, because 50 per cent. of the severe cases of phthisis fail to react. Slight and moderate cases of phthisis react only exceptionally. 3. Typhoid patients exhibit a positive ophthalmoreaction to tuberculin very frequently, especially during convalescence. 4. A subcutaneous injection of tuberculin made some time after the instillation is able

to call forth again the local reaction in the eye, or to produce it in case it failed to appear before. 5. The single instillation induces in nontuberculous adults, not children, after a sufficient length of time, a hypersensitiveness of the eye into which the instillation was made; in tuberculous patients this action is usually extended to the other eye also.

**5. Forensic Value and Knowledge of the Joining of the Complements.**—Bruck says that the præcipitin reaction retains its old importance in the distinction of albumin of animal or human origin in forensic practice. At the same time the method of complement joining is not only quite equal in value to the præcipitin reaction, but is superior in fineness and distinctness of its results, and should therefore be used in every forensic case as the supplement of the præcipitin reaction. The great delicacy of the reaction forbids the use of too strong immune sera and necessitates an investigation by one who is perfectly familiar with the sources of error of the reaction. The use of weak immune sera enables the method of complement joining not only to make the absolutely specific diagnosis of human albumin, but also renders it possible to distinguish which of the albuminous fluids of the body produced the spot in question—i. e., a distinction between blood, pus, semen, etc., and this should be determined in this manner in every forensic case.

13. Impressions of America (Concluded), By MÜLLER.

**1. Artificial Pneumothorax in Tuberculosis, Bronchiectasis, and Aspiration Diseases.**—Schmidt says that one should always try to make the first infusion of air so as to strike a pleural adhesion; that among the cases which are fitted apparently for the compression treatment there is a not small part, 22.7 per cent. of the cases reported in Germany, in which the production of complete pneumothorax is rendered impossible because of the presence of pleural adhesions; that one should not be discouraged by a failure on the first attempt, but should repeat the puncture in different places so as to produce several separated, sacculated pneumo-

thoraces. He has employed this form of treatment in thirteen cases of pulmonary tuberculosis, eight of bronchiectasis and three of aspiration disease, pneumonia, or fetid bronchitis. Involvement of the other lung he considers a distinct contraindication to the treatment. On the whole he believes that the number of cases which are truly benefited by compression treatment is limited.

**2. The Smallest Necessary Supply of Albumin.**—Forster concludes from his observations that a sufficient quantity of other substances, such as ash, than albumin, fat, and carbohydrates, are necessary to the upbuilding and maintenance of human organs; that these substances are met with in the food in combination with albuminous substances, or at least in relation with albumin, and it is therefore to be feared that with a more reduced supply of albumin nutrition will suffer from lack of these ash constituents. With the breaking up of albumin in the body certain necessary materials, digestive ferments, and other derivatives of albumin, are formed. For some it is proved, for others it is probable, that the production is in proportion to the decomposition of albumin in the body. It is, therefore, to be expected that with reduced assimilation of albumin slight disturbances of the general condition and diseases would occur through want of these materials. As long as the proportions, both qualitative and quantitative, are no better understood than they are at present it is advisable for the purpose of practical nutrition from the general physiological and hygienic standpoint to maintain a large assimilation of albumin and not to limit this to the physiological minimum by which the so called balance of nitrogen may be maintained in a given case.

**4. Hæmorrhage Into the Fatty Capsule of the Kidney.**—Doll gives the clinical picture of this condition. Vascular diseases which increase the blood tension, such as arteriosclerosis, chronic nephritis, syphilis, and alcoholism, form the ætiological basis. Very severe colicky pain recurring at short intervals in the region of the kidneys, which radiate backward and downward, but not to the scrotum or penis, soon followed by tenderness on pressure and on change of position in the region where the pain is located. Then in the region of the kidney, behind the colon, an elongated tumor with indistinct margins becomes recognizable with increasing clearness by percussion and palpation, tender, tensely elastic, not moving with respiration. Fever is moderate, remittent, toward the end appear higher ranges of temperature, with occasional attacks of collapse. Symptoms of moderate anemia, rapid loss of strength, and bad pulse follow. The diaphragm presses upward, and symptoms of consolidation of the lower lobes of the lungs and of exudates in the pleural cavities are to be seen. Meteorism when at its maximum renders the tumor indistinct. Doughy cutaneous swellings appear in the lumbar region with bluish black effusions of blood there and in the scrotum. Two cases are described, one of which has been reported before.

**5. Treatment of Epidemic Cerebrospinal Meningitis.**—Többen speaks strongly in favor of the results obtained in this disease by the combination

of lumbar puncture and injection of meningococcus serum.

9. **Foreign Bodies in Upper Jaw the Cause of Conjunctivitis.**—Thorey reports a case in which a man sought relief for a conjunctivitis associated with a very profuse discharge of pus, that was out of proportion to the changes in the conjunctiva and lids. Local treatment for three weeks was without effect and then close questioning elicited the history of an injury four years before and a knife blade was discovered in the nose. The location was perfected by means of the x rays and the removal of the foreign body was followed by an immediate cessation of the ocular symptoms.

10. **Interesting Case of Foreign Body in the Nose.**—Mühlenkamp reports a case in which he removed a knife blade from the nose of a man who stated, as soon as he saw it that he must have been wounded with it in a fight two years before.

9. Observations upon Certain Blood Pressure Lowering Reflexes that Arise from Irritation of the Inflamed Pleura, By J. A. CLAFFS and D. D. LEWIS.

1. **The Medical versus the Surgical Treatment of Gastric Ulcer.**—Musser affirms that this is a medical disease, which, with its complications and sequels, may become surgical. With perforation it is surgical; with hæmorrhage it is medical, unless the hæmorrhage is frequently repeated. It is still medical when there is perversion of secretory function, unless motor disturbances become prominent. It is surgical with signs of retention from obstruction, dilatation, hour glass contraction, or adhesions. If, in spite of medical treatment, its symptoms threaten life, if there are repeated hæmorrhages and consequent anæmia, it is surgical. Surgical treatment often becomes a necessity on account of neglect of medical treatment during a long period of incipency. The physician for a case of gastric ulcer should early associate himself with a surgeon of ability and experience in order to meet with promptness any emergencies that may arise. After surgical procedures have been carried out the case should be treated medicinally for at least four months, and hygienically and dietetically for several years.

2. **Indications for, Methods of, and Results to Be Expected from Medical Treatment of Gastric Ulcer.**—Stockton summarizes the medical treatment as follows: The aim should be to secure

a calm mind, a quiet nervous system, and improvement of the general health. A positive diagnosis should be made, treatment should be begun early, and its details carefully carried out. Complete rest should be enforced. In some cases there should be moderate feeding, in others starvation for a time, with dependence upon enemata of salt solution. For hæmorrhage, in addition to rest, one should introduce ice water through a stomach tube, and, if necessary, adrenalin solution, followed by gelatine water. If there is irritating hyperacidity, local general sedatives and antacids are indicated. For hypertension and spasm of the stomach, in addition to proper drugs, use external applications after von Leube's method. Continue treatment long after apparent cure, studying the stools for occult blood.

3. **Studies on Arteriosclerosis, with Especial Reference to the Radial Artery.**—Thayer and Fabyan think the following inferences are justifiable in the presence of a thickened radial artery: If it occurs in an old person it represents conditions which are normal and to be expected, not only in central but in peripheral vessels. If it occurs in earlier life it may mean (1) that the vessel has been subjected to unusual and exceptional strain, or that (2) it is a vessel which, from inherent weakness or other individual circumstances, has been unable to cope with conditions which would ordinarily be regarded as normal. In either of these two latter conditions the artery has been obliged to fortify itself by progressive thickening of its walls, especially by a connective tissue sclerosis of its intima and media. When there is marked thickening of a radial artery there are usually similar changes in the intima of the mesenteric artery and the aorta. An unduly palpable, radial artery indicates possible regressive changes of a dangerous character in other parts of the body.

4. **The Significance of Tubercle Bacilli in the Fæces.**—Rosenberger gives the following results of his investigations in fifty-seven cases: 1. No acid fast bacillus except the tubercle bacillus was found in the fæces. 2. The presence of this organism in the fæces means that there is active tuberculosis in some portion of the body. 3. In acute military tuberculosis the bacillus is always present in the fæces. 4. In all cases of chronic diarrhœa and in cases of general glandular involvement the fæces should be examined for tubercle bacilli. 5. If tubercle bacilli are found in the fæces it does not necessarily signify that there is intestinal ulceration in all cases. 6. In arrested or healed pulmonary tuberculosis no tubercle bacilli will be found in the sputum or fæces. 7. The fæces should be studied for tubercle bacilli as a part of routine examination, especially in cases in which no sputum can be obtained.

5. **Acute Intussusception in the Adult.**—Ross and Page state that one third of the cases of intestinal obstruction are due to this cause. Its three varieties of the enteric, the colic and the ileocolic. The ileocolic form of the ileocolic is the one most frequently observed. The condition is due to irregular action of the intestinal muscular fibres. There may be spasmodic invagination and paralytic invagination, clinically the former alone being met with, and in most cases it is descending in its development.

The causes for this condition may be ptomaine poisoning, enteric fever, traumatism, and benign or malignant growths of the bowel. The onset is usually sudden, being influenced by the portion of bowel attacked. The first and most persistent symptom is pain, which is colicky and intermittent at first, then moderates, and may cease when gangrene occurs. When the invagination is fixed the pain is located in the area of involved bowel. Vomiting occurs at intervals with temporary relief. Muscular rigidity and abdominal distension are absent in the period. Diarrhœa and abdominal tenderness are of frequent occurrence. There is seldom any abdominal tumor or elevation of temperature. Tenesmus and bloody stools are of frequent occurrence. Early diagnosis and operation give the best hope for successful results.

#### 6. Primary Carcinoma of the Urinary Bladder.—Brown reaches the following conclusions:

1. Intelligent deductions and trustworthy statistics are to be derived only from the careful and thorough study of a large number of cases from both the clinical and the anatomical standpoints.
2. The most frequent seat of carcinoma in the bladder and the direction of its extension are still matters of uncertainty.
3. Metastasis occurs much more frequently than many clinicians are willing to admit.
4. A malignant growth in the bones may occur from a primary carcinoma of the urinary bladder.
5. The most frequent cause of death in vesical carcinoma is a secondary infection of the ascending urinary tract.
6. The diagnosis is always difficult, and it is especially so after complications have occurred.

20. A Telephonic Curette, By A. C. JACOBSON.

5. On Two Cases of Abdominal Section for Trauma of the Uterus.—Bland Sutton narrates two important cases illustrating the possible dan-

gers of curettage. In the first case a physician curetted a non gravid uterus for painful menstruation. The uterus being sufficiently dilated, the operator introduced his finger into the uterus, felt a soft substance, seized it with forceps, and continued to pull until a large mass was in the vagina. The pulling was so vigorous that one end gave way and the other end was then cut off with scissors. The tissue was found to be small intestine. Eight hours later Sutton was called to see the patient, who was in collapse from hæmorrhage. The abdomen was opened and found full of blood. The perforation in the uterus was closed, and the mutilated ileum joined to the ileocæcal aperture from which it had been torn. The patient recovered. In the second case dilatation of the uterus was performed for painful menstruation, and the uterus ruptured extensively, letting coils of intestine pass into the vagina. There was little bleeding, but much shock. The abdomen was opened, a large rent found on the posterior wall of the cervix, and ten ounces of blood in the pelvis. Supravaginal hysterectomy was performed, the ovaries and tubes being retained. This patient also recovered.

#### 8. Intraabdominal Torsion of the Omentum without Hernia.—Skeel observes that this condition is not an infrequent one and that most of the cases are associated with hernia. He classifies omental torsion as follows:

1. Torsion with hernia in which the omentum is in the hernial sac and is there twisted, or twisted both in the sac and in the abdomen, or adherent to the sac and rotated above it.
2. Torsion of the omentum in the abdomen, hernia also being present or having previously existed, with no apparent connection between omentum and sac.
3. Pure intraabdominal torsion with no history of hernia. The following theories as to causation are propounded: 1. Causes acting externally only. 2. Internal force, as intestinal peristalsis, or external force, as pressure, causing rotation, the tip of the omentum being readily converted into a ball. 3. The same forces acting upon an omentum adherent at the tip. 4. Circulatory changes leading to twisting of the veins around the more resistant arteries.

#### 11. The Conservative Medical Treatment of Salpingitis.—Ill observes that perseverance, judgment, and patience are necessary to make such treatment effective. There are plenty of cases which are not suitable for such treatment which should be treated surgically. He divides the cases which are suitable into three classes, as follows:

1. Those in which the acute febrile condition results from the extension of a gonorrhœal vaginitis and endometritis into the tubes and to the pelvic peritonæum. Such cases include not only catarrhal salpingitis, but cases in which suppuration has resulted.
2. Those in which there is an acute febrile condition due to a variety of poisons following labor, abortion, and unclean intrauterine instrumentation.
3. Those which result from inflammatory conditions following tubal abortion and which have been neglected for a long time. The treatment consists essentially of rest in bed, vaginal douches, counter-irritation at the roof of the vagina, and local depleting measures.

## Proceedings of Societies.

### SOUTHERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.

*Twentieth Annual Session, Held in New Orleans,  
December 17, 18, and 19, 1907.*

The President, Dr. HOWARD A. KELLY, of Baltimore, in the Chair.

**Perinephritic Abscess Following Parturition.**—Dr. J. SHELTON HORSLEY, of Richmond, Va., reported three cases in which he had operated, and called attention to the necessity for early diagnosis in order to give the patient the benefit of a prompt operation, as all statistics showed that the mortality of this disease increased as the operation was delayed. He laid stress upon the occurrence of pain in either flank a few weeks after parturition, even in cases of comparatively aseptic delivery. The bending of the body to the affected side, stiffness of the spine, slight limp in walking, and pain on pressure over the affected flank were important early symptoms. Later there was muscular spasm, and a decided mass could be felt over the region of the kidney. Constipation was always marked, due partly to the patient's dread of muscular effort. The usual constitutional signs of sepsis appeared as the disease progressed. In all his cases the abscess had been on the right side. He attributed this to the fact that the right kidney and perinephritic tissue were lower than the left, and consequently were more likely to be injured by the bearing down pressure during parturition. This afforded a point of least resistance in the perinephritic tissues of the right side, and germs which were absorbed by the lymphatics of the uterus might readily gain a foothold here. Treatment should follow the diagnosis at once, and should consist in a lumbar incision, as in an operation for nephrotomy, and drainage with a tube of large calibre.

**Postoperative Complications in Abdominal Surgery.**—Dr. CHARLES M. ROSSER, of Dallas, Tex., said, among other things, that shock, whether due to basic inhibition or vasomotor paresis, could not be overcome by stimulants to an already exhausted nerve centre, but position for the purpose of relieving cerebral anæmia from hemorrhage, saline solutions to enlarge the volume of the blood current, adrenalin to restore the equilibrium of the blood pressure, and morphine to give balance to the flagging vital forces were the remedies. A rubber bandage or a suit, by limiting circulatory necessity, might be used either as a precaution or as a treatment. Postoperative peritonitis resulted from excessive trauma or infection. Drainage was the best safeguard after asepsis. If required, reopening for drainage was to be done with the least possible trauma, and the minimum amount of anæsthetic. Ileus or other obstruction might be treated by an enema of alum solution, which reversed peristalsis and gas distention, or by egg turpentine emulsion thrown high up. Inhalation pneumonia suggested mouth and pharynx antiseptics, and was treated in the usual way. Hypostatic pneumonia was not so common since physicians did not insist upon decubitus as a routine.

**Some Postoperative Complications of Peritonitis.** Dr. RANDOLPH WINSLOW, of Baltimore,

read a paper on this subject in which he reported the histories of two cases that had recently occurred in his practice. One of them was a case of appendicitis with peritonitis, followed by intestinal obstruction from adhesions. A cure was effected by operation. The patient was a girl, twenty years of age.

The second case was one of appendicitis and peritonitis followed by extensive adhesions, causing intestinal obstruction. Enterostomy was performed, followed by anastomosis and subsequently by resection and enterorrhaphy. This patient was a man, aged nineteen. The operations were successful.

**Acute Dilatation of the Stomach as a Postoperative Complication.**—Dr. C. JEFF MILLER, of New Orleans, said that among the unexpected complications that might arise after surgical operations no condition was more distressing than acute dilatation of the stomach. This complication was probably as serious as any that might arise. The latest statistics, gathered by Simpson, showed that, in 128 cases, in eighty-six the patients had died. Kayser's collection of sixty cases, quoted by Bloodgood, yielded 71 per cent. of deaths. Conner's exhaustive study of 102 cases showed seventy-four deaths, or 72.5 per cent., and twenty-eight recoveries.

The treatment was summed up as follows, namely, early recognition, prompt emptying and washing of the stomach, and such posture as might release a mesenteric compression. To these might be added any eliminative measure indicated, if the emunctory organs were inactive. Early diagnosis was essential to successful treatment. Judging from the cases reported in which an operation had been done with the idea of relieving obstruction, surgery was not encouraging. In spite of the high mortality, however, there was strong evidence to prove that many patients could be saved by prompt treatment. The author reported a case in which he had operated successfully.

Dr. HENRY T. BYFORD, of Chicago, said that his experience had been that the longer the anæsthesia the less nausea there was, and the slower the patient came out from under the influence of the anæsthetic the less nausea there was. He had found it advantageous to give from one to two ounces of brandy just before giving the anæsthetic, in order to diminish the amount of anæsthetic necessary, as by so doing there was much less lung irritation. He had also noticed the good effect of giving an enema after an operation, putting into the enema one half or one ounce of alcohol.

Dr. GEORGE BEN JOHNSTON, of Richmond, Va., could not agree with Dr. Byford that prolonged anæsthesia was prudent. The smallest quantity of any anæsthetic should be given, and the anæsthesia should occupy as little time as possible. These conducted to the welfare of the patient.

As to complications, the most important thing was the prompt recognition of them. Fatalities from them occurred because they were not promptly recognized, and therefore not promptly treated. A careful study of every postoperative case would enable the experienced clinician to recognize an approaching dilatation of the stomach, and if that condition was quickly recognized and energetically treated, fully 33 per cent. of the patients would recover. The stomach should not be washed out in these cases.

at stated intervals, but as soon as the condition was recognized prompt lavage should be practised and continued as long as there was any indication of vomiting.

Dr. RUFUS B. HALL, of Cincinnati, speaking of abdominal distention, referred to the value of the hypodermic use of eserine in 1/50 or 1/100 grain doses. Within forty minutes after its administration the patient would begin to pass gas. His rule had been to give patients the fiftieth of a grain under the skin, and within forty minutes, if the patient was not relieved by passing great quantities of gas, the dose was repeated. It was rare, however, that he had had to give a second dose. He had used this remedy for about two years in more than thirty cases, and in only one had it failed to bring on the prompt elimination of the gas.

Dr. W. P. CARR, of Washington, had had good results from eserine in a number of cases, and where he had had the stomachs of patients washed out directly after operation, and had given them a dose of eserine when they left the table, there had been very little trouble from distention by gas or in getting the bowels to move afterward. Washing out the stomach after an operation and giving the thirtieth of a grain of eserine on the table was very effective as a routine practice, except where the bowels were open and where one did not want to cause very much peristalsis. It was effective only when there was something in the bowel. If the bowel was empty, eserine did not seem to have any effect.

Dr. CHARLES H. MAYO, of Rochester, Minn., referring to acute dilatation of the stomach, said there was a great amount of discomfort following operations in these cases, many of the patients dying. They died because on the second, the third, or the fourth day they showed a marked condition of regurgitation. These patients would vomit a peculiar greenish material in large quantities. Two or three quarts might be vomited suddenly. The lower part of the abdomen was flat, while the upper part was distended. The condition would persist for four days, when there might be a profuse diarrhoea. The condition could be met successfully in many cases by lavage as long as the stomach showed a tendency to refill. Many of these patients, after three or four washings of the stomach, within the third day would be entirely relieved; intestinal peristalsis would begin, and gas would escape. In some of the more severe cases the patient could be saved by gastrojejunostomy done between the fifth and seventh days as a secondary operation.

Dr. HERMAN J. BOLDT, of New York, did not think the mortality from acute dilatation of the stomach was so high as had been stated. However, it was a comparatively frequent and undesirable complication after abdominal section. Whenever there was the slightest evidence of an inflammatory process in the peritonæum, salicylate of eserine did no good, so that one must be careful in the selection of his cases. Early mobilization of the patients would prevent some of these postoperative complications.

Dr. J. M. MASON, of Birmingham, Ala., mentioned a patient who had acute dilatation of the stomach on the day following an operation, but who was entirely relieved by getting rid of the Fowler position, elevating the foot of the bed, and resorting to lavage.

Dr. HUBERT A. ROYSTER, of Raleigh, N. C., reported a case of acute dilatation of the stomach following an operation for the fixation of both kidneys. The patient, however, died on the fourth day after efforts to relieve her.

Dr. JOHN YOUNG BROWN, of St. Louis, had had twenty-eight cases of diffuse peritonitis, and since he began the treatment recommended by Bond his mortality had been greatly reduced, whereas prior to that time, when he irrigated, his mortality was high. It was not so much the Fowler position as it was in getting these patients to move about in bed, thus preventing the complications that were formerly observed. Of ten cases treated without the Fowler position, the results were equally good as in those treated with it. He contended that by following a simple technique at the primary operation complications which would otherwise arise might be prevented.

Dr. I. S. STONE, of Washington, thought that after doing good surgical work the bowels of the patient should be allowed to rest. When a surgeon gave purgatives immediately after operations, he thought he defeated the very purpose he ought to attempt to accomplish. He had done quite a number of operations in the last five years, and had not had a single case of death from ileus.

Dr. EDWARD H. OCHSNER, of Chicago, said the sooner surgeons learned to recognize that rest favored repair, and that motion favored adhesions, the better it would be for them and for their patients.

**Transperitoneal Removal of Tumors of the Bladder.**—Dr. CHARLES H. MAYO, of Rochester, Minn., said that a large percentage of early recurrences following the removal of bladder tumors, both benign and malignant, indicated a delayed operation or imperfect removal. With the increasing interest in cystoscopy, early operating was becoming more common. The ineffective operation was due, in part at least, to imperfect exposure of the operative field. The transperitoneal operation was advised in cases of large tumors, benign or malignant, of the bladder. With the patient in the Trendelenburg posture, the bladder empty, a long median incision was made over the bladder, the peritonæum opened, and the intestines walled off into the upper abdomen by large gauze pads in the operative field. The bladder was drawn up into the wound and opened through the peritoneal covering on its posterior superior aspect. The cavity was now dried with gauze and the incision enlarged forward or back two or three inches, the tumor excised, and the area involved treated with the Paquelin cautery. In some cases large areas of the bladder, even two thirds of it, might be resected. The opening was closed by catgut suture protected on its peritoneal side by a linen suture of the Cushing type. The abdominal incision was closed usually without drainage. In the after care, repeated use of the catheter for a few days, if necessary, was to be preferred in uncomplicated cases.

**Treatment of the Bladder After Suprapubic Cystostomy for Stone.**—Dr. WILLIAM S. GOLDSMITH, of Atlanta, said the principles governing the treatment of the bladder after suprapubic cystostomy were: 1. The immediate and complete closure of the bladder and abdominal wound. 2. The institution of urethral retention catheter drainage. A series

of external urethrotomy cases, in which the retention catheter method had been used, and following the closure of the perineal incision, had convinced him of its efficiency and of the tolerance of the bladder for these unusual conditions. Perfect urethral drainage was such a necessity that failure in securing successful results was attributed to some imperfections of this important factor of treatment. Large stones could not be removed through small incisions without seriously lacerating the mucous membrane and other coats and leaving a ragged, lacerated suture line altogether unsurgical in character, and encouraging tissue necrosis with eventual bad results. Upon the removal of the foreign body the wound was protected with gauze, the patient turned upon his side, and the bladder thoroughly irrigated with the urethral catheter. The wound was closed tight with interrupted silk sutures, introduced down to but not through the mucous membrane. The abdominal incision was closed with small chromic catgut and cotton and collodion applied. Elaborate abdominal dressings were not used, for the reason that they served no purpose other than to interfere with the freedom of the patient in turning from side to side. In adults, and particularly men of middle age, posture was a most important detail. The ability to turn on either side and the insistence of frequent change of position stimulated urinary secretions, prevented puddling of urine, and insured a clean, collapsed cavity, which at once began a regeneration of exhausted anatomical and physiological vitality. The semierect, and finally the erect, position was rapidly assumed, and every effort was directed along the line of forced recuperation and rapid convalescence.

**The Treatment of Fibroid Tumors of the Uterus Complicated by Pregnancy.**—Dr. LEWIS S. McMURTRY, of Louisville, alluded to the indications for surgical intervention in cases of fibromyomata complicating pregnancy, with special reference to the time for such intervention, and the plan and scope of the operative procedure in the varying conditions presented. Uterine fibromyomata were very commonly associated with sterility. The association of pregnancy with uterine fibromyomata added very materially to the dangers of this condition; new dangers would arise from the combination of the two; and, while the clinical fact that a considerable proportion of the cases came through in safety was indisputable, the mortality of the entire number of cases left to nature was high.

To illustrate the advantage of prompt operative intervention in properly selected cases, the author reported four cases. These he had selected for the purpose of illustrating the multifarious aspects of uterine fibromyomata complicated by pregnancy as clinically presented. His entire experience consisted of two more cases, in which an operation was done in the early period of pregnancy, making six cases in all, and all the patients had recovered. While indiscriminate operation in uterine fibromyomata associated with pregnancy was not to be advised, the mortality of this condition when unaided was so great as to justify an extension of the field of operative treatment, both myomectomy and hysteromyomectomy; and every case should receive individual consideration, so that a judicious selection of cases for operation might be observed.

Dr. GEORGE H. NOBLE, of Atlanta, said that where the pelvis was impacted completely, as he had seen in a number of cases, where it was impossible to make a digital examination, and the upper part of the uterus was smooth, free from the tumor, the surgeon might do one of two things, Cesarean section or myomectomy. Since Cesarean section was a simple operation, it would be desirable in the interest of the mother and of the fetus. Myomectomy could be carried much further in well selected cases.

Dr. HERMAN J. BOLDT, of New York, said that a woman in about the third month of gestation had consulted him as to whether or not she was pregnant. She had missed the menstrual period twice, and the physician whom she first consulted informed her that she had a tumor which required immediate removal. Examination revealed a tumor in the lower anterior segment of the uterus, a fibromyoma of the interstitial variety; at the same time, she was pregnant. At the time she consulted him he advised noninterference, but added that if any serious symptoms were encountered it might be necessary later to do a Cesarean section in case she could not be delivered naturally. Myomectomy was decided on and done to prevent an abortion. The woman made a perfect recovery. She was now eight months pregnant.

Dr. HENRY D. FRY, of Washington, said that, in addition to the dangers mentioned by the essayist, we must recognize the increased danger in these cases from post partum hemorrhage. The retraction of the uterus was not sufficient at the site of the placental attachment, and post partum hemorrhage was likely to occur. Again, if the woman passed through labor satisfactorily and safely, there might be infection or necrosis of the fibroids. He had had that occur twice in his own work, where the women had been delivered safely, and their puerperium was complicated by septic fever. Supravaginal hysterectomy was done. The women got well, but in cutting down on the tumor it was found to be disintegrated and necrotic. As to the time of operation for these fibroid tumors, he thought surgeons ought to tide the cases along until the child reached the period of viability—got as near the full term of gestation as possible—and then do a Cesarean section and supravaginal amputation of the uterus.

Dr. ERNEST C. LEWIS, of New Orleans, mentioned the case of a woman, five months pregnant, who had a fibroid attached to the body of the uterus and filling about one half of the pelvis. It was not suspected until it caused pressure symptoms and pain. Her family physician sent for him, and a fibroid which could not be pushed above the brim of the pelvis was diagnosed. The cervix was pressed against the symphysis pubis. The abdomen was opened, the tumor enucleated from the back portion of the uterus, the abdomen closed, and the patient made an uneventful recovery, went to full term, and was delivered by her family physician with forceps. He referred to another case in which the woman was more advanced in pregnancy.

Dr. J. WISNEY BOWER, of Washington, thought there were a great many women who would go to full term and be delivered naturally with fibroid tumors of the uterus, so that he thought we could not lay down any fast rule that would apply to ex-

ery case. Each case was to be considered individually. If any operation was to be done, it was well to follow the plan Dr. Fry mentioned. The speaker was loath, however, to do a myomectomy where the growth was intimately connected with the body of the uterus, as he felt it would be apt to induce abortion. The case of Dr. Boldt impressed him as being unique from the fact that an operation was done to prevent abortion, and abortion did not occur, although it was threatened before the operation was done. As a rule, he would expect the opposite to be the case, and he doubted whether surgeons could follow Dr. Boldt's plan as a routine measure. In a number of cases he had done myomectomy without interference with pregnancy.

Dr. GEORGE BEN JOHNSTON, of Richmond, believed that when fibroids could be removed early in pregnancy, this should be done, but unfortunately many of the cases did not come to the surgeon until a stage of pregnancy had been reached when this could not be safely done. When a pregnancy was known to exist and was complicated by fibroids, such a patient should be closely watched, so that a prompt operation might be performed if necessary. In this way the rights of the unborn child could be respected, and it was not uncommon for such a pregnancy to go on to the period when the child was viable. He had had experience in fifteen cases in which he had operated for fibroids complicating pregnancy. But his experience had been doleful in the matter of saving the children. He had not had a fatality among the mothers, but had been able to save only one child out of these fifteen cases.

**The Treatment of Dislocation of the Shoulder Joint Complicated with Fracture of the Upper Extremity of the Humerus.**—Dr. J. M. MASON, of Birmingham, reported the case of a man who had sustained a subcoracoid dislocation of both shoulders with fracture of the surgical neck of the right humerus. The left shoulder was reduced by the Kocher method, and the right was treated by arthrotomy and reduction six hours after the receipt of the injury. The fracture was wired and primary union was secured. A perfect result was obtained, and the patient had neither atrophy, pain, nor weakness in the arm, and there was no restriction of motion in any direction. A comparison of the results in the shoulder subjected to operation with those where simple reduction of the uncomplicated dislocation was practised showed no difference.

The author's conclusions were: 1. Every dislocation of the shoulder associated with fracture of the upper extremity of the humerus was a grave injury and was likely to result in serious impairment of function if not promptly treated. 2. Every such injury should be subjected to x ray examination for accuracy in diagnosis. 3. Gentleness should characterize all manipulative efforts at reduction, and these should not be carried to the point of bruising or lacerating the tissues. 4. Excision should be practised only where open arthrotomy had failed, where there was extensive comminution of the upper extremity of the humerus, or where, in fracture at the anatomical neck, the condition of the upper fragment did not justify a reasonable expectancy of its uniting. 5. After reduction, the broken greater tuberosity should be nailed down if the case was recent, and should be removed if it caused impairment of function in an

old case. 6. In failure to reduce by manipulation, immediate arthrotomy with reduction of the dislocation, followed by appropriate treatment for the fracture, had given the best results and was the ideal method of treatment. 7. Rigid asepsis was essential in securing good results, and these operations should not be undertaken where this could not be carried out.

(To be continued.)

## Letters to the Editors.

### PRACTICAL AND SCIENTIFIC NEUROLOGY.

CHICAGO, December 12, 1907.

To the Editors:

Neurology as a branch of scientific biology and neurology as a department of medical practice are still widely apart. This is obvious enough to any one who follows the literature of both.

Take as a ready, though perhaps not the best, illustration the book reviews that appear in the high class journals. Note how sharply separated are the reviews of the clinical works from those of the works devoted to pure science. In practically all of the periodicals devoted to physiology, comparative anatomy, and psychology the newer works upon nervous diseases and psychiatry are wholly ignored; or, if they are reviewed therein at all, only those parts of the book are criticised that touch upon pure physiology, anatomy, and psychology. In a sense, this of course is as it should be; but I, for one, should like to read now and then a careful and honest review of a book upon nervous diseases by a capable critic whose training had been wholly, or almost wholly, in the pure biological sciences. I fancy such a one would have some amusing and not unprofitable things to say about some of the unphysiological, unscientific, and altogether unwarranted deductions occasionally indulged in by the teachers and writers trained only in clinical medicine. Some of the crude deductions of the pathologists also would be easily shattered, I am sure, by such a critic.

On the other hand, while the magazines devoted to clinical neurology are more frank to review the newer works upon neurophysiology and neurobiology generally than are the magazines devoted to pure science to review the newer works upon clinical neurology, such reviews, as a rule, are woefully flat and inadequate, and reveal often in a most glaring manner the critic's unfamiliarity with the latest authoritative teachings of experimental and comparative neurology. Did space and courtesy permit, one could easily quote from some recent reviews and authoritative scientific works matter sufficient to make a long series of parallel paragraphs showing the contradictions and misstatements upon the part of the reviewer indicative of a lamentable ignorance in one who pretends to so exalted and delicate a position as that of critic.

Often have I wondered what the net result would be if by some miracle the investigators and writers in the field of pure biology and biophysiology could be made to study clinical neurology for one year, and if all the clinicians, pathologists, and writers in the realm of neurological practice could be forced to study for the same length of time the pure bio-

logical sciences, including psychology. I have a notion that were such a miraculous event to be brought about, a large part of our present literature upon neuropathology, clinical neurology, and practical phychiatry would undergo immediate and extensive revision, if it was not wholly assigned to the limbo of oblivion.

As there is not the remotest hope of such a surprising event occurring, the confusion and resultant pessimism that are so prevalent in the rank and file of the profession in connection with the diseases of the nervous system, which, in my opinion, are largely due to the state of affairs intimated above, might be dissipated to a very considerable extent if the medical schools would teach more scientific biology and physiopathology along with practical neurology.

L. HARRISON METTLER.

#### RIDING ASTRIDE BY WOMEN.

MOUNT HOLLY, N. J., December 16, 1907.

To the Editors:

In answer to Dr. E. H. Bidwell's inquiry in the last week's issue, regarding fashion having more weight than the opinion of physicians, I would say that it is the general opinion among the physicians with whom I associate that the fashion of riding astride has not had its origin in fad so much as it has in the advice of physicians of our modern type.

That this method caused a greater frequency of uterine trouble than the side saddle method it would be hard to explain.

The fact that a person riding astride can have more freedom from jar and jolt than one riding on a side saddle should be a point in favor of the astride method, aside from the facts of it being safer and easier for the rider. The fact that it might be considered immodest by those who are not familiar with the astride method of riding is no reason why it should be condemned. The main reason why it is becoming more popular is because physicians in general see its good points over the old method and are thus advising it.

H. R. FARINGER.

#### NEUROLOGICAL HOSPITALS.

1009 CHESTNUT STREET,  
PHILADELPHIA, December 26, 1907.

To the Editors.

In the issue of your journal for December 21st there is an editorial on the establishment of a neurological hospital on Blackwell's Island. This article is written in the interest of what I believe should be regarded as one of the most important and most beneficent movements ever contemplated or consummated by the great city of New York. The writer of your editorial, however, while showing an admirable knowledge of what has been done abroad in the interests of sufferers from diseases of the nervous system and for the advancement of scientific neurology, exhibits at the same time an extraordinary lack of information of what has been done in his own country. He speaks of this neurological hospital on Blackwell's Island as "practically the first of its kind in this country," while calling attention to the Salpêtrière and Bicêtre hospitals of Paris.

Apparently the writer is entirely unacquainted with the fact that no less than thirty years ago a department for the study and treatment of nervous diseases was established in connection with the Philadelphia Hospital and Almshouse. It is the more remarkable that this lack of information should exist when it is remembered that the neurological department of the Philadelphia Hospital has been visited by most of our confrères in New York.

In the *Journal of Nervous and Mental Disease* for June, 1904, in a History of Neurology in Philadelphia from 1874 to 1904, is given a brief account of the origin and development of the neurological department of the Philadelphia Hospital, and in an article in the *Philadelphia Hospital Reports*, vol. v, 1902, a more extended history of this department will be found. To these articles I would refer your writer and any others who might chance to be interested in the matter. The number of patients in this neurological hospital is now about four hundred; it is expected that in a short time this number will reach five hundred and more. It may be worthy of note that many of the articles contributed to the neurological journal above referred to during the last two decades have been based upon the study of clinical and pathological material obtained from the wards of this hospital.

The wards of the neurological department of the Philadelphia Hospital have been visited by neurologists from all parts of our own country and from many foreign countries, including Great Britain, France, Germany, Italy, Switzerland, and Russia; these visitors in almost every instance have compared these wards favorably with those of the Salpêtrière and Bicêtre.

In Philadelphia there is another hospital for nervous diseases, which might perhaps have received at least passing notice from a writer interested in the foundation of a new American neurological institution. This is the Orthopedic Hospital and Infirmary for Nervous Diseases, which was founded in 1867, ten years before the nervous wards of the Philadelphia General Hospital, and has now grown into an institution of large proportions, where all forms of nervous disease, acute and chronic, are studied and treated. It may be said, however, that this great hospital and infirmary is not exactly like that which is contemplated in New York, which presumably will develop more or less upon the lines of the neurological department of the Philadelphia Hospital.

I trust that in your valuable journal, which represents in its title both New York and Philadelphia, you will give place for this brief statement of facts, that neither any of your contributors nor any of your readers may longer remain in ignorance of the fact that we have had for more than thirty years in Philadelphia at least two neurological hospitals worthy of the name, and that it may not appear that hospitals, like prophets, are not without honor save in their own country and among their own kin.

It gives me pleasure, in behalf of my colleagues of the neurological staff of the Philadelphia Hospital, to extend an invitation to any of those interested in the establishment of the new neurological hospital in New York to visit our institution and study its workings.

CHARLES K. MILES.

## Book Notices.

*Surgery: Its Principles and Practice.* By Various Authors. Edited by WILLIAM WILLIAMS KEEN, M. D., LL. D., Professor of the Principles of Surgery, Jefferson Medical College, Philadelphia. Volume II. With 572 Text Illustrations and 9 Colored Plates. Philadelphia and London: W. B. Saunders Company, 1907. Pp. 920. (Price, \$7.)

In this second volume Dr. E. H. Nichols is the author of the chapter on diseases of the bones; Dr. D. N. Eisendrath has written the chapters on fractures and dislocations; Dr. R. W. Lovett has prepared the chapters on the surgery of the joints and orthopaedic surgery; Dr. J. F. Binnie is the author of the chapter on the surgery of the muscles, tendons, and bursæ; Dr. F. H. Gerrish has furnished that on the surgery of the lymphatic system; Dr. J. A. Fordyce has contributed that on the surgery of the skin; Dr. W. G. Spiller has written that on the pathology of the chief surgical disorders of the nervous system; Dr. G. Woolsey has prepared those on the surgery of the nerves and the surgery of the spine; Dr. F. X. Dercum has contributed that on traumatic neurasthenia, traumatic hysteria, and traumatic insanity, and J. C. DaCosta has furnished that on surgery among the insane and the surgery of insanity.

Each of the subjects is treated admirably, the text is well illustrated, and the volume is a fit companion to its excellent predecessor.

*A Textbook of Mental and Sick Nursing.* Adapted for Medical Officers and Nurses in Private and Public Asylums. By ROBERT JONES, M. D., B. S. Lond., F. R. C. S. Eng., F. R. C. P. Lond., Resident Physician and Superintendent of the London County Council's Asylum, Claybury, etc. With an Introduction by Sir WILLIAM JOE COLLINS, M. D., M. S., B. Sc. Lond., F. R. C. S. Eng., M. P., D. L., J. P., Vice-Chancellor of the University of London, etc. London: The Scientific Press, Limited, 1907. Pp. 222. (Price, 3s. 6d.)

The author has had a wide experience in the treatment of mental disorders, and as superintendent of one of the largest of London's county asylums is daily brought in contact with the type of questions constantly arising in this branch of medicine. While mental disease is to be considered first, last, and always as bodily disease, in no wise different in principle from any other disease to which flesh is heir, yet certain features of the nursing of mental cases make it desirable to issue works of this kind.

This volume is formed of the substance of a series of lectures delivered by the author at Claybury, which have from time to time appeared in the columns of the *Hospital*. They show the author's point of view to be that held by leading men throughout the world, that to be a good nurse or attendant on the insane it is requisite to be a good general nurse and something more. He emphasizes, and wisely so, the fact that certain qualities of knowledge and character, certain qualities of mind and of heart, are not less but more essential than is the case with the general nurse.

To this end he assumes a certain knowledge and then discusses in some twenty-four chapters the special features which need emphasizing when one is called upon to treat the insane, the feeble minded, and the epileptic.

We can commend it as a convenient and compact

manual, well written and filled with practical suggestions.

*The Reduction of Cancer.* By the Hon. Rollo Russell. London and New York: Longmans, Green & Co., 1907. Pp. 62.

The author believes that the origin and increase of cancer are to be attributed to the habit of excessive meat eating, the abuse of alcohol, and the overindulgence in tea, coffee, and tobacco among civilized peoples. This view is apparently supported to some extent by a consideration of the geographical distribution of cancer and by an ingenious use of quotations and opinions of medical authorities which have been in some cases at least strained to bear the interpretation the writer gives them. We believe we are quite within the mark in saying that any competent scientific investigator would hesitate to draw from such meagre data the sweeping conclusions indicated in the little book.

*A Manual of Clinical Diagnosis by Means of Microscopical and Chemical Methods.* For Students, Hospital Physicians, and Practitioners. By CHARLES E. SIMON, B. A., M. D., Professor of Clinical Pathology at the Baltimore Medical College, etc. Sixth Edition, Thoroughly Revised. Illustrated with 177 Engravings and 24 Plates in Colors. Philadelphia and New York: Lea Brothers & Co., 1907. Pp. xix-17 to 682.

Dr. Simon has introduced a great amount of new material into the sixth edition of his *Clinical Diagnosis*. It is about ten years ago that the first edition was published, and since that time many new discoveries in medicine have been made and many new theories advanced. The author has well adapted his book to the advances of our science. In this edition we find a new chapter on the opsonins, with a full description of the technique, in which Dr. Simon's experience as a pioneer worker will certainly prove of value. Two appendices have also been added, the first dealing with the preparation of culture media, the second representing an outline of a course in clinical laboratory methods.

The illustrations are well executed. It is usually a stumbling block for the artist to represent his objects in natural colors. The difference between the natural object and the object as depicted in the illustration is often so great as to make recognition impossible. Not so in our book. The *nuances* are well selected, giving a true gradation of the fine differences of shade in colors. The author mentions Mrs. Simon as the painter of most of the illustrations.

*Fiske Fund Prize Dissertation. No. L. Diet in Typhoid Fever.* By JOHN BENJAMIN NICHOLS, M. D. Providence: Snow & Farnham Company, Printers, 1907.

In his prize essay the author presents an excellent historical sketch of feeding in fevers from the earliest times, and there is a careful analysis of the entire subject of metabolism in typhoid based upon the original authorities, with a comparison of different food values, and in conclusion a plea is made for the adoption of a more liberal diet in typhoid fever, and to it we give our decided assent.

*Synonymik der Dermatologie.* Von DR. JOHANNES FICK, Wien. Wien und Leipzig: Alfred Holder, 1906. Pp. 68.

The little pamphlet is a practical reference book for dermatologists, especially those using the German language. It is arranged alphabetically, the explanations to be found under the Latin name, to

which cross references of English, French, and German nomenclature refer.

*Annales de la Société royale des sciences médicales et naturelles de Bruxelles.* Soixante-huitième année. Tome xvi, Fasc. i et 2. Bruxelles: Henri Lamertin, 1907. Pp. 345.

This volume of the *Annales* contains four interesting essays: 1. A contribution to the Study of Ruptures of the Gravid Uterus and to the Physiology of the Trophoblast, by Bouffart and Delporte. 2. The Influence of the Peptones on the Functions of the Kidneys, by George Hendrik. 3. Experiments with Salts upon the Pancreatic Juice, by Edgard Zunz. 4. The Action of Camphor and Oxycamphor upon the Heart of the Turtle after Extirpation, by Adrien Lippens.

#### BOOKS, PAMPHLETS, ETC., RECEIVED.

*Practical Anæsthetics.* By H. Edmund G. Boyle, M. R. C. S., L. R. C. P., Assistant Anæsthetist to St. Bartholomew's Hospital, etc. London: Henry Frowde and Hodder & Stoughton, 1907. Pp. viii-178.

Abel's Laboratory Handbook of Bacteriology. Translated from the Tenth German Edition, by M. H. Gordon, M. A., M. D. (Oxon.), B. Sc., with Additions by Dr. A. C. Houston, Dr. T. J. Horder, and the Translator. London: Henry Frowde and Hodder & Stoughton, 1907. Pp. x-224.

Die Praxis der Hautkrankheiten. Unna's Lehren für Studierende und Aerzte, zusammengefasst und dargestellt von Dr. Iwan Bloch, Berlin. Mit einem Vorwort von Dr. P. G. Unna in Hamburg. Mit 92 Abbildungen. Berlin und Wien: Urban & Schwarzenberg, 1908. Pp. 698.

Les Homosexuels de Berlin. Par le Dr. Magnus Hirschfeld. Paris: Jules Roussel, 1908. Pp. 103.

Schema des Rumpfes. Von Privatdozent Dr. W. Hildebrandt, Freiburg i. B. Taschenausgabe. München: J. F. Lehmann, 1908.

Les Ferments métalliques et leur emploi en thérapeutique. Par Professeur Albert Robin, membre de l'Académie de Médecine. Paris: J. Rueff, 1907. Pp. 252.

Traitement de la tuberculose par la paratoxine basé sur l'action antitoxique du foie. Par E. Gérard, professeur de pharmacie et de pharmacologie, and G. Lemoine, professeur de clinique médicale à l'Université de Lille.

Traité clinique des maladies de l'estomac. Par le Dr. Lucien Pron (d'Alger). Paris: Jules Roussel, 1908. Pp. 417.

Die tierischen Parasiten des Menschen. Ein Handbuch für Studierende und Aerzte. Von Dr. Max Braun, o. ö. Professor der Zoologie und vergl. Anatomie, etc. Mit 325 Abbildungen im Text. Vierte, vermehrte und verbesserte Auflage. Mit einem klinisch-therapeutischen Anhang. Bearbeitet von Prof. Dr. Otto Seifert in Würzburg. Würzburg: Curt Kabitzsch (A. Stuber), 1908. Pp. 623.

Traité pratique d'hypnotisme et de suggestion thérapeutiques. Procédés d'hypnotisation, simples, rapides, inoffensifs. A l'usage des médecins, pharmaciens, professeurs, instituteurs et des gens du monde. Par M. Géraud Bonnet, docteur en médecine de la Faculté de Paris, etc. Deuxième édition. Paris: Jules Roussel, 1907. Pp. 320.

### Official News.

#### Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon General, United States Public Health and Marine Hospital Service, during the week ending January 3, 1908:

#### Army Intelligence:

Official list of changes in the status and duties of officers serving in the medical department of the United States Army for the week ending January 4, 1908:

BROWN, O. G., Assistant Surgeon. Relieved from further temporary duty at Jefferson Barracks, Mo., and ordered to return to his proper station, Fort Robinson, Neb.

CROSBY, W. D., Major and Surgeon. Appointed a member of a board of officers to meet at the Army Medical Museum Building in Washington, D. C., for the examination of such officers of the medical department

as may be ordered before it to determine their fitness for advancement or promotion.

DUNCAN, L. C., Captain and Assistant Surgeon. Granted four months' leave of absence with permission to go beyond the sea.

FLAGG, C. E. B., Captain and Assistant Surgeon. Relieved from duty at Fort Creek, Neb., and ordered to the Philippine Islands for duty on transport to sail from San Francisco, Cal., about February 5, 1908.

GREENLEAF, H. S., Captain and Surgeon. Relieved from duty in the Philippine Islands, and ordered to proceed on the transport to sail from Manila, on or about March 15, 1908, to San Francisco, Cal.; upon arrival will report by telegraph to the Adjutant General of the Army for further orders.

MCCAW, W. D., Major and Surgeon. Appointed a member of a board of officers to meet at the Army Medical Museum Building in Washington, D. C., for the examination of such officers of the medical department as may be ordered before it to determine their fitness for advancement or promotion. Appointed a member of a board to meet in Washington, D. C., for the purpose of conducting such experiments as may be necessary regarding the efficiency of the Darnall filter for the purification of water, and its adaptability to the use of troops in the field.

MORRIS, E. R., Major and Surgeon. Appointed a member of a board to meet at Jeffersonville, Ind., for the examination of such officers of the quartermaster's department as may be ordered before it to determine their fitness for promotion.

MUNSON, E. L., Major and Surgeon. Appointed a member of board to meet at Jeffersonville, Ind., for the examination of such officers of the quartermaster's department as may be ordered before it to determine their fitness for promotion.

OWEN, L. J., First Lieutenant and Assistant Surgeon. Upon expiration of his present leave of absence, will proceed to Columbus Barracks, Ohio, for duty.

POWELL, J. L., Major and Surgeon. Leave of absence extended ten days.

RICHARDS, R. L., First Lieutenant and Assistant Surgeon. Ordered to report in person on January 14, 1908, to Major W. D. Crosby, surgeon, president of the examining board, Washington, D. C., for examination to determine his fitness for advancement.

RUSSELL, F. F., Major and Assistant Surgeon. Appointed a member of a board to meet in Washington, D. C., for the purpose of conducting such experiments as may be necessary regarding the efficiency of the Darnall filter for the purification of water, and its adaptability to the use of troops in the field.

SHIMER, I. A., Captain and Surgeon. Ordered to report in person on Tuesday, January 7, 1908, to Major William D. Crosby, surgeon, president of the examining board, Army Medical Museum, Washington, D. C., for examination to determine his fitness for promotion. Relieved from duty as attending surgeon in New York City, and ordered to the Philippine Islands for duty, to sail from San Francisco, Cal., about February 5, 1908.

WILLIAMS, A. W., Captain and Assistant Surgeon. Relieved from duty in the Philippine Islands, and will proceed on the transport to sail from Manila on or about March 15, 1908, to San Francisco, Cal., and upon arrival report by telegraph to the Adjutant General of the Army for further orders.

WINTER, F. A., Major and Surgeon. Appointed a member of a board of officers to meet at the Army Medical Museum Building in Washington, D. C., for the examination of such officers of the medical department as may be ordered before it to determine their fitness for advancement or promotion.

### Navy Intelligence:

*Official list of changes in the medical corps of the United States Navy for the week ending January 4, 1908:*

DESSEZ, P. T., Assistant Surgeon. Detached from the Naval Hospital, Boston, Mass., and ordered to the naval recruiting station, Kansas City, Mo.

MICHELIS, R. H., Passed Assistant Surgeon. Detached from the naval recruiting station, Kansas City, Mo.

SELLERS, F. E., Assistant Surgeon. Detached from the Wilmington and ordered to the Naval Hospital, Annapolis, Md.

## Births, Marriages, and Deaths.

### Married.

DAVENPORT—MILLS.—In Rochester, New York, on Wednesday, January 1st, Dr. Howard Irving Davenport, of Canandaigua, and Miss H. Helena Mills.

HEIMANN—DAVISON.—In New York, on Wednesday, January 1st, Dr. Walter James Heimann and Miss Heloise Davison, daughter of Dr. David H. Davison.

LANGE—RICK.—In Pittsburgh, Pennsylvania, on Monday, December 23d, Dr. J. C. Lange and Mrs. Edith Rick.

MALONE—FRANZONI.—In Washington, D. C., on Saturday, December 28th, Dr. Wilson P. Malone and Miss Edith Elizabeth Franzoni, daughter of Dr. Joseph D. Franzoni.

SCOTT—LAYCOCK.—In Bethel, Ohio, on Wednesday, December 25th, Dr. J. C. Scott and Miss Leona Laycock.

SELLERS—LOSEY.—In Louisville, Kentucky, on Wednesday, December 25th, Dr. Harry W. Sellers and Miss Ethel Losey.

WOODFORD—CROGHAN.—In Washington, D. C., on Thursday, December 26th, Dr. William G. Woodford and Miss Beatrice Anne Croghan.

### Died.

AUSTEN.—In New York, on Tuesday, December 31st, Peter Townsend Austen, Ph. D., aged fifty-five years.

BANKS.—In Oak Forest, Cumberland County, Virginia, on Monday, December 23d, Dr. J. L. Banks.

BLAKE.—In Tampa, Florida, on Thursday, November 28th, Dr. B. F. M. Blake, of Brooklyn, aged fifty-two years.

BOICE.—In Denver, Colorado, on Saturday, December 28th, Dr. John Boice, aged sixty-eight years.

BOWEN.—In Buffalo, New York, on Saturday, December 28th, Dr. Clara E. Bowen, aged forty-seven years.

BURGESS.—In Huntington, Long Island, on Friday, December 27th, Dr. Frederick Wells Burgess, aged eighty-six years.

COTTRELL.—In Boston, Massachusetts, on Saturday, December 28th, Dr. W. J. Cottrell, aged thirty-six years.

CROOK.—In Glenwood Springs, Colorado, on Tuesday, December 24th, Mrs. Olive W. Crook, wife of Dr. W. W. Crook.

EAGER.—In Louisville, Kentucky, on Saturday, December 28th, Dr. Benjamin F. Eager, aged fifty-nine years.

EGELHOFF.—In Chicago, on Friday, December 27th, Dr. William C. Egelhoff, aged thirty-five years.

HAMILTON.—In Peoria, Illinois, on Sunday, December 29th, Dr. William R. Hamilton, aged ninety-two years.

HARDENBERG.—In Jersey City, New Jersey, on Tuesday, December 31st, Dr. Daniel S. Hardenberg, aged sixty-seven years.

HAYES.—In Buffalo, on Thursday, December 26th, Dr. W. Carlos Hayes, aged fifty-six years.

HIGGINS.—In Glendale, Missouri, on Wednesday, December 25th, Dr. Richard M. Higgins, aged sixty-five years.

HUMES.—In Upper Marlboro, Maryland, on Tuesday, December 24th, Dr. Mareen D. Humes, aged fifty-seven years.

JEWETT.—In Cohat, Connecticut, on Friday, January 3d, Dr. Levi Jewett, aged seventy-three years.

MARSHALL.—In Chicago, on Monday, December 23d, Dr. David Marshall, of Florence, Kentucky, aged twenty-four years.

MARSHALL.—In Bedford City, Virginia, on Friday, December 27th, Dr. Thomas H. Marshall, aged seventy-two years.

PIERCE.—In Newburgh, New York, on Sunday, December 29th, Dr. Louis R. Pierce, aged forty-one years.

REULING.—In Baltimore, Maryland, on Saturday, December 28th, Dr. Robert C. Reuling, son of Dr. George Reuling, aged thirty-five years.

SCHUGENS.—In Buffalo, New York, on Wednesday, December 25th, Dr. M. Elizabeth Schugens.

SENN.—In Chicago, on Thursday, January 2d, Dr. Nicholas Senn, aged sixty-three years.

SMITH.—In Frankton, Virginia, on Monday, December 30th, Dr. Charles Smith, aged seventy-two years.

SMITH.—In Richmond, Virginia, on Friday, December 27th, Dr. Robert F. Smith, aged sixty-five years.

TAYLOR.—In New York, on Sunday, January 5th, Dr. Robert W. Taylor, aged sixty-five years.

WACHENDORF.—In Sioux Falls, South Dakota, on Saturday, December 28th, Dr. C. C. J. Wachendorf.

WILLIAMS.—In Peakes, Hanover County, Virginia, on Tuesday, December 31st, Dr. Thomas E. Williams.

## INCORPORATING THE

*A Weekly Review of Medicine, Established 1843.*

WHOLE No. 1520.

\*Revised list are the Model A and B. The model A is the model B with N = 1. October 20, 2000.

its most dependent portion. It is necessary to carry in mind which part of the loop is the upper and which the lower, as it must be attached in such manner that the peristaltic wave of the jejunum will travel in the same direction as that of the

very serious objection, it is true; the three bladed clamp, however, overcomes this objection and enables one to make the apposition precisely exact.

When the instrument is once in place it requires no further attention and hence eliminates to some extent the assistants' hands. The organs being in

FIG. 2.—Two clamps holding segments of stomach and intestine in place, ready for anastomosis. The clamps are covered with rubber tubes. The concavity of the clamps does not show in the drawing, as we stand directly in front of the concave side. The tying together of the clamps is not represented in the figure.

place, our territory is first well surrounded by gauze, and then we proceed to the suture, which consists of an outer, seromuscular suture and an inner row through all the coats. Some prefer a triple layer, dividing the inner row into two subdivisions, one suture taking mucosa only, the other, serosa and muscularis.

I shall describe the method of suture in two rows. Beginning at one end we insert a continuous silk

FIG. 1.—Krause's clamp for anastomosis.

stomach; in other words, the oral part of the loop should be on the left side. The anastomosis should be about three inches long, if possible. It is usually made nowadays with the aid of long curved clamps (Fig. 1). One of these is made to clasp the segment of the stomach which is to enter into the anastomosis, the other the corresponding equally large segment of the jejunum (Fig. 2). These clamps are closed tightly enough to hold the organs firmly, but not so tightly as to crush them. The blades of the instrument are usually covered with rubber tubes. The clamps are then properly approximated and tied together so that they may not change their relative position to each other. Instead of two clamps, a single three bladed clamp may be employed, which holds both organs in proper apposition. The Roosevelt clamp (Fig. 3) is constructed to serve this purpose. I have used it quite a number of times and find it very efficient. In fact, it has advantages over the two bladed clamps. For instance, in tying the two bladed clamps together it is necessary to place the handles of the one on top of those of the other. In consequence of this the segments of stomach and intestine will not be in exactly the same plane, not a

FIG. 3.—Roosevelt clamp.

suture, which is to be everywhere about one quarter inch distant from the proposed incisions into the two organs (Fig. 4). When the posterior half of the serous suture is completed, a clamp is applied to

the silk thread close to the viscus to prevent the meshes of the suture from loosening. Needle and thread are then covered so they will not be soiled during the next step, when the lumen of the stomach and of the intestine is opened. An incision is now made into the stomach and intestine; the cuts in

FIG. 4.—First half of the seromuscular suture inserted. The suture is represented as beginning on the left, its termination on the right being secured by a clamp to prevent it from loosening. The incisions into the stomach and intestine are indicated by lines above and below the suture. Notice that these incisions are shorter than the seromuscular suture. The two incisions are equal in length.

both organs being exactly equal in length are one quarter inch shorter at each end than the serous suture first applied. It is well to incise only the serous coat at first, because the clean cut into that layer will enable us to judge very easily whether the cuts are equal in length and in proper relative position. The incisions are now deepened down to the mucosa, which is then incised. In the case of the intestine the mucosa usually bulges somewhat, so that some prefer to excise the bulging portion. It is of the utmost importance for us to be conscious that at this stage of the operation our work ceases to be aseptic and that any instrument or

FIG. 5.—Application of the continuous mattress suture. The knot is at "a" both ends of the thread being armed with needles. In the diagram, in order to show how the stitches run, the sutures are represented as being separated; in reality, of course, they are brought into close apposition.

instrument that has come in contact with the mucosa of the opened organs is not to be used again for the aseptic part of the operation before being re-sterilized. The mucosa is wiped clean with a piece of gauze moistened with saline solution—some prefer a 2 per cent. lysol solution—and then we proceed to apply the second row of sutures, or, better,

a continuous suture, through all layers, employing for this purpose either an over and over suture or the mattress stitch (Fig. 5), the latter having my preference. In the diagram, in order to show how the stitches run, the surfaces are represented as being separated; in reality, of course, they are brought into close apposition. This suture is first applied to the posterior lips of the gastroenterostomy wound, which are already in perfect apposition, so that its performance is very simple. The suture is then continued along the anterior lips of the wound, where its application is not so easy. With a little ingenuity, however, and the knowledge that the serous coats must be brought into apposition, any one can readily figure out how the thread must run.

FIG. 6.—Continuous mattress stitch, showing how the corner is turned. To show the method the stitches are represented as being left loose; in the actual procedure each stitch is at once tightened. The knot is at "a"; observe that it is not placed at the angle and that, starting from it, the thread runs in both directions.

The accompanying diagram (Fig. 6) may help to illustrate the method with the use of the continuous mattress stitch, showing how the corner is turned. In the diagram, to show the method, the stitches are represented as being left loose; in the actual procedure each stitch is at once tightened. Only the last two or three stitches are not at once drawn close, as otherwise there would not be room enough to insert the needle at the mucous surface; hence, to continue the mattress stitch to the end, these last few stitches must be left loose till the sutures are all in place, when they are tightened and the suture is closed. Some to whom this is too troublesome finish up by one or two seromuscular sutures, inserted from the serous side; but a suture finished in this manner is not so perfect, as it is not so sure to control hemorrhage. Another point in the application of the suture is this: Most surgeons start the suture at one angle with, having

gone completely around, end up at that same angle. It seems to me that the adaptation at the angle is more perfect, if the knot at that place is eliminated. I therefore begin at some place other than the angle (compare Fig. 6, where the knot is not at the angle,

FIG. 7.—Diagram showing the condition at the anastomosis in case a vicious circle is produced. The distended oral loop presses upon the anal loop, almost occluding its lumen.

but near it), make my knot, leaving both ends long and arming each end with a needle, then going round part of the way with one needle and the other part with the other needle, the meshes of the first suture being meanwhile prevented from loosening by the application of a clamp. Thus I end up, not at one of the angles, but at the front surface of the united lips. The advantage of this is that the last stitches, the correct insertion of which is not quite simple, are placed at the most easily accessible part.

The anastomosis is now complete with the exception of the superficial portion of the seromuscular suture, the posterior half of which was inserted at the very beginning of the anastomosis and the loose end of which was held by a clamp to prevent the stitches from opening (Fig. 4). Before inserting the anterior half of this seromuscular suture, we must not forget that now the unclean part of the operation is completed. We therefore cleanse the last suture line with saline or lysol solution, remove the gauze compresses immediately surrounding the anastomosis, and replace them by clean ones. We change our gloves or cleanse them, we discard all soiled instruments, and then proceed with the consciousness that now again we are in position to do strictly aseptic work. Furthermore, the lumen of the gut being now closed, we no longer need the clamps. They are therefore removed, although, if desired, one blade may be left behind the anastomosis to prevent the organs from slipping back into the abdomen; if a strip of gauze has been first inserted between the two organs, as is usually done, this alone is sufficient to prevent slipping back. Then the anterior half of the seromuscular continuous suture is applied and knotted at the place where the first half began.

A complication that is occasionally encountered

after gastroenterostomy is the so called vicious circle. That is a condition in which the contents of the stomach, having passed through the pylorus, the duodenum, and the upper part of the jejunum to the gastroenterostomy opening, are stopped there, unable to get down into the intestine beyond the anastomosis. In consequence of this the intestine between the pylorus and the anastomosis becomes distended until its contents are regurgitated into the stomach and vomited. The obstruction at the anastomosis opening is usually brought on by the fact that the spur between the oral and anal loop is pressed toward the anal loop, closing its lumen (Fig. 7). This is more likely to occur when the anastomotic opening is small than when its dimensions are ample; for, where the attachment of intestine to stomach is extensive, the production of a sharp spur is avoided. Again, the vicious circle will be observed where the anastomosis is so placed that the stomach cannot easily empty itself through it, i. e., if the intestine is attached too high up on the stomach. In the third place, it is also more apt to occur when the pylorus is patent than when it is much constricted; in cases of excessive stenosis at the pylorus there is very little danger of a vicious circle being established, as all the chyme must leave the stomach through the gastroenterostomy opening.

These three causes for the production of a vicious circle suggest their own remedies. To avoid the first, the anastomotic opening should be made larger; to avoid the second, it should be placed at as low a part of the stomach as possible; two desiderata which were already mentioned in the description of the operation. To meet the third condition, that of a well open pylorus, it has been proposed to close the pylorus artificially by a ligature tied around it. A certain way, however, of pre-

FIG. 8.—Enteroenterostomy added to gastroenterostomy to prevent vicious circle.

venting this complication is to establish an anastomosis between the proximal and distal limbs of the loop used for gastroenterostomy (Fig. 8). Or else, as Roux prefers, we may divide the intestine completely at the place chosen for anastomosis, im-

planting the distal end into the stomach and the proximal end, by an end to side anastomosis, into the intestine below the gastroenterostomy opening (Fig. 9). The former of these two methods, being

FIG. 9.—Roux's method to prevent a vicious circle. The intestine is divided completely; the distal end is implanted into the stomach, the proximal end into the distal portion of the intestine.

the easier to perform, is the one preferred by most surgeons.

To perform posterior gastroenterostomy the posterior wall of the stomach is exposed by turning upward the transverse colon and dividing the trans-

FIG. 10.—Operation, modified, showing the use of the three-bladed clamp. The first portion of the gastroenterostomy suture has been inserted, the organs are shown incised, ready for the deep-through and through suture.

verse mesocolon at a place where the vessels can be avoided. In this way the stomach is exposed. As for the jejunum, instead of selecting a place

about eighteen inches from the duodenojejunal fold, a place as high up as possible is chosen, so that practically the short piece of jejunum above the anastomosis does not form a loop at all, but lies close up against the stomach. If, in posterior gastroenterostomy, this method is adopted and a sufficiently large opening is established, the vicious circle is effectually avoided. The technique of the operation is the same as in anterior gastroenterostomy; but after the anastomosis is completed, the divided mesocolon should be attached by a few stitches to the intestine. This serves a double purpose; first, it affords an additional cover over the suture uniting stomach

FIG. 11.—Stump of stomach after pyloroplasty. The stomach has been closed by suture except at its lowest part where the duodenum is to be joined to it.

and jejunum, and secondly, it prevents the possibility of an internal hernia through the mesocolon.

Although I have described the operation of anterior gastroenterostomy first and more extensively than posterior gastroenterostomy, I must state that the latter is my choice and that of most other surgeons, for it enables one better to reach a deep portion of the stomach than the anterior operation, and the possibility of pressure of the jejunum and the transverse colon on each other is avoided. It may, however, be impossible to perform posterior gastroenterostomy owing to extensive infiltration of the posterior wall of the stomach through carcinoma or otherwise. Again, posterior gastroenterostomy may be very difficult if the stomach is small and the posterior suture therefore cannot

be thoroughly brought forward. It is easy of performance if the stomach is dilated. The operation of posterior gastroenterostomy will therefore be found simpler if performed to relieve pyloric obstruction than if performed for gastric hæmorrhage without obstruction.

Kocher's gastroduodenostomy must also be mentioned as a method of anastomosis between stomach and intestine. It has the advantage of using the highest possible portion of the intestine for anastomosis. It should not be performed if there is infiltration or immobility of the pylorus or duodenum. It is also apt to be unsatisfactory in cases of extreme dilatation with atony, because in those cases

ready for insertion of the deep suture through all the layers.

Resection of the stomach is practised mainly for the removal of carcinoma and most frequently consists in an excision of the pyloric portion of the stomach, pylorotomy, much more rarely of an excision of other parts of the stomach. The condition which offers a chance of success is that the growth is circumscribed; the size of the tumor is less important. A case of successful removal of a carcinoma of the pylorus that was large enough to be distinctly seen through the abdominal wall, which I reported (*Medical Record*, June 6, 1906), is an instance to show that even a large tumor may be favorable for excision if only it is circumscribed. This latter point we will often be unable to determine before the abdomen is opened.

The operation is performed as follows: A short

FIG. 12.—First and last turns of duodenum to stomach, after pylorotomy with the aid of the three bladed clamp. The deep portion of the seromuscular suture has been inserted.

FIG. 13.—Next step after Fig. 12. Through and through mattress suture. The thread is armed with a needle at each end. At the lower portion the corner is being turned.

the anastomotic opening may be considerably higher than the greater curvature, and drainage would therefore be imperfect.

The operation for pyloroplasty is much less practised than formerly, as the functional results are not as satisfactory as those of gastroenterostomy. Pyloroplasty should not be performed if the pylorus is infiltrated or fixed. Of the various methods the best is Finney's operation, which affords a large opening, the incision extending so well into the stomach and the duodenum that the operation might well be classed as a gastroenterostomy. Fig. 10 represents a modification of Finney's operation showing the use of the three bladed clamp. The first portion of the seromuscular suture has been made, and the incision into the organs is shown,

median epigastric incision is first made for diagnostic purposes. It may appear after opening the peritoneal cavity that a resection is impossible. If we decide to do nothing, the incision is closed again. If a gastroenterostomy is decided upon, the incision is lengthened to four or five inches, and if we determine to perform a resection, it may be necessary to lengthen the incision to six or eight inches. In that case, the incision is prolonged downward into the mesogastrium by either going around one side of the umbilicus or by excising it. The pyloric portion of the stomach is drawn well forward, and the extent of the tumor, the extent to which the lymphatic glands are affected, and the intimacy of the adhesions are ascertained. At this time the question has to be decided whether it will be possible, after resecting amply in healthy tissues, to reunite the duodenum with the stomach without causing undue tension. If this is possible, then Billroth's first method or Kocher's method is performed. If it is not possible, the duodenum and the stomach are closed by suture, after the resection has been

done, and a gastroenterostomy is performed. A weak point in this latter method of operating is the suture closing the duodenum. It has not infrequently been found that the stomach contents, discharged through the anastomosis, have in part flowed into the ascending loop and caused so great a degree of tension that the suture at the duodenum was not able to withstand it. At any rate, notwithstanding the assertions of some that the suture is a safe one, peritonitis due to leakage at the duodenal suture has been found at autopsies. The accident could probably always be avoided if an enteroenterostomy between ascending and descending loops were made. According to Mikulicz, the safest closure of the duodenum is by a purse string suture.

Let us assume that the duodenum and stomach can be united after resection; and this is possible in most cases that are at all suitable for resection, especially if we follow Kocher's method of mobilizing the duodenum by incising the posterior parietal peritonæum over the right kidney in a line parallel

Accordingly, the duodenum should be resected at a distance of one inch from the tumor, the stomach about two to four inches from the tumor, depending upon the greater or less sharpness with which the border of the tumor is defined. To prevent the outflow of the contents of the stomach or intestine, appropriate clamps are applied at a distance of about an inch beyond the proposed site of the resection at the duodenum and stomach. The clamps are to compress the organs just sufficiently; they should not crush the tissues. The ends of the resected portion are also closed by clamps, before the division is made. The excision having been performed, the stomach is closed again by sutures, except at its lowest part, where the duodenum is to be united to it (Fig. 11).

This suture consists of two rows. The inner row, a continuous silk suture, is applied from within, beginning at the lesser curvature, going through all layers and inverting the cut borders, so that serous coat is in contact with serous coat. The outer

FIG. 11. Kocher's method of pyloroplasty. A continuous mattress suture is applied behind the closed clamps.

to the descending portion of the duodenum, about one inch to the right of it. Billroth's first method, modernized, is performed in the following way: The gastrocolic ligament at the greater curvature and the lesser omentum at the lesser curvature are tied off and divided to the desired extent, that extent being determined by the distribution of the tumor and the involvement of the lymphatic glands. At the lesser curvature the lymphatic glands are distributed far up, so that here the resection must be made quite near to the cardia. In the course of this step of the operation the main arteries are tied, *viz.*, the gastric and pyloric above, and the right and left gastroepiploic below. Instead of the right gastroepiploic, occasionally the gastroduodenal is tied. The greater and lesser curvatures have now been liberated, after which the tumor, with the adjacent parts of stomach and duodenum, *i. e.*, the part that is to be resected, is loosened completely around. The duodenum must be thoroughly liberated.

As a rule, the border of the tumor is quite sharply marked at the duodenum, less so at the stomach.

row is a seromuscular Lembert suture, likewise continuous, which still further inverts the stomach at its cut border and, like the first row, extends from the lesser curvature to the part which is left open. This open portion is then united to the duodenum in a similar manner by two rows of sutures, the inner one applied from within and going through all layers, the outer, a seromuscular suture. The suture is best applied in the same manner as that described for gastroenterostomy; in fact, if desired, the three bladed instrument may be employed (Fig. 12). First, the posterior surfaces of stomach and duodenum are united by a seromuscular suture; then a mattress suture through all layers unites the divided ends, the same as in gastroenterostomy (Fig. 13). Finally, the seromuscular suture which was first applied is continued on the anterior surfaces of the stomach and duodenum. The insertion of the seromuscular suture necessitates the invagination, to a slight extent, of the duodenum into the stomach. As the stump of the stomach is funnel shaped while the duodenum is

cylindrical, there will be a somewhat greater extent of serous surface on the stomach after invagination than on the duodenum, a condition which, on inserting the seromuscular suture, may occasionally require a plication of the stomach at some place. Instead of the suture a Murphy button may be used to unite duodenum and stomach.

Kocher's method of uniting the duodenum with

FIG. 15.—Next step after Fig. 14. An over and over suture is placed over the mattress suture.

the stomach is to close the stomach completely and make an end to side implantation of the duodenum into the posterior wall of the stomach. The stomach may be closed in a manner similar to that outlined in the foregoing description of Billroth's first method; Kocher, however, prefers to make the closure as follows: Both stomach and duodenum are divided between clamps applied so tightly that they crush the tissues, the division being made as close as possible to the clamp attached to that part of the organ which remains. The tight hold which the clamps have on the organs facilitates handling these. The stomach is then sewed up by a continuous mattress suture applied behind the closed clamp (Fig. 14). Then the clamp is removed, while the suture is held on a stretch by making traction at each end of it; the edges, especially the mucosa, are trimmed, if necessary, and an over and over suture is superimposed over the first one (Fig. 15). This closes the stomach securely. A third row, a continuous seromuscular suture, then completely buries the preceding ones. Now, the duodenum, still firmly closed by a tightly holding clamp, is brought into apposition with the posterior wall of the stomach and united with it by sutures in-

serted in a manner similar to that described for gastroenterostomy. Before opening the stomach and duodenum to apply the through and through suture, the outflow of intestinal and stomach contents must be guarded against. This is done, according to Kocher, for the duodenum by a gently compressing clamp or a ligature; for the stomach by the use of a clamp or the assistant's hands. Another way is with the use of the three bladed instrument as described for gastroenterostomy, which grasps in one of its clamps the duodenum in its entire circumference, in the other clamp that segment of the stomach which is to enter into the anastomosis (Fig. 16). The clamp that closes the end of the duodenum is removed by closely cutting off the duodenum behind its grasp. The through and through suture is then inserted from the mucous membrane side, and over this comes a seromuscular suture, the continuation of the first one inserted. In this operation, the same as in gastroenterostomy,

FIG. 16.—Anastomosis of end of duodenum with posterior surface of stomach after pylorectomy. The three bladed clamp is employed. The posterior seromuscular suture has been inserted. The clamp that closed the end of the duodenum has been removed by cutting off the duodenum behind its grasp. The incision into the stomach has been made.

it is of the utmost importance to be conscious at what stage the operation ceases to be strictly aseptic. Accordingly we protect the peritoneal cavity carefully by gauze before the gastroenteric tract is opened. We must also understand that hands and instruments used at this part of the operation are not sterile, and that, when the alimentary tract is closed again, they must not be used at the subsequent clean part of the operation without being re-sterilized. When the intraperitoneal work is com-

pleted, the abdominal wall is closed without drainage.

Excision of the entire stomach has been performed. It is rare to find a case suitable for this operation, for in cases where the stomach is so extensively involved as to require its entire removal that operation would, as a rule, do no good owing to the involvement of other organs.

Excisions of parts of the stomach other than the pyloric portion is indicated in cases of localized carcinoma and in some cases of ulcer. The excision in those cases is also performed with the aid of clamps, and is shaped, if possible, so that the closure may be made by a linear suture, as any combination of sutures meeting at an angle is less reliable.

Of the remaining operations upon the stomach, the most important is gastrostomy, the construction of an abdominal gastric fistula. This operation is performed for obstruction in the œsophagus, either benign or malignant, and the gastric fistula

FIG. 17.—Diagram of Roux's method of separating a loop of jejunum to replace the œsophagus.

which is established will be either temporary or permanent, according as the cause of the obstruction is removable or not. The formation of an oblique fistula according to Witzel, and of a direct one according to Kader, are the two methods used most frequently. They consist essentially in a plication or an inversion of the wall of the stomach upon itself in such manner that a canal lined by the serous coat of the stomach is formed. Whereas formerly, after this canal had become firmly united with the abdominal wall, it was the custom to remove the tube and introduce it only for purposes of feeding, it is now left *in situ*, as the gastric fistula proved to have a tendency to close, and some difficulty was frequently experienced in reintroducing the tube.

One of the most interesting operations for establishing a new access to the stomach for introducing food is one which Roux performed upon animals, viz., to excise a portion of jejunum having a long mesentery to which it remains attached. The anal end of the excised portion is implanted into the stomach while the oral end is carried underneath the skin of the thorax up to the neck, where it is brought out, the intention being to unite it with the œsophagus by a subsequent operation (Fig. 17). The ends from which the jejunal loop has been resected are, of course, united with each other. Roux ligated a few of the vessels in the mesojejunum to secure greater mobility, preserving, however, the peripheral arches, and found that the jejunum remained sufficiently nourished. A stomach tube is introduced through the transplanted intestine into the stomach. It is evident that the method is applicable only under very favorable conditions as to the vascular supply of the jejunal segment.

When we look over the progress that has been made in the surgery of the stomach during the last few years, we find that it consists mainly in an elaboration of certain details in the technique, including improvement in the construction of certain instruments. Improved technique helps us to guard our asepsis still more strictly and also enables us to employ the suture much more frequently, where formerly we preferred mechanical appliances like the button. It is, therefore, in this branch of surgery the same as in all other branches, the attention to minute details which is responsible for a great part of the progress made in the art and the improvement in the results achieved.

#### VARICOSE VEINS.

*Their Treatment by Multiple Short Incision.\**

By C. F. KIVLIN, M. D.,  
Troy, N. Y.

Dilated and tortuous veins are spoken of as varices, or varicose veins. This abnormal condition is dependent in some way upon an interference with the flow of blood in the veins. Thus gravity plays its part, since the trouble is most common in the veins of the legs and since it is most often seen in tall people than in short ones. Age and disease of the heart, producing imperfect valvular action, are also potent factors. The change is not due to the atrophy of old age, as it is usually noticed before the fortieth year, and in a great many instances before the twenty-fifth year. It is equally difficult to explain why the veins of one leg should be much dilated and tortuous while those of the other are scarcely affected, or why in certain persons the large veins are chiefly affected, and in others the smaller radicles in the skin. As muscular contraction and muscular relaxation constitute the chief aids to venous flow, it is not surprising that persons who are obliged to stand for hours at a time (washerwomen, car motormen, etc.) suffer more from this trouble than those who are constantly changing their positions. While any of the veins of the lower extremity may be affected, the trouble is most often found in some

\*Read before the Rochester County Medical Society at session held on May 14, 1901.

of the radicles of the internal saphenous vein. The tortuous and dilated vessels are easily recognized on inspection, and if they lie near the surface their bluish color is visible through the skin. If they are not or have not been inflamed, they collapse under moderate pressure and disappear almost entirely when the foot is elevated. In some places their channels through the skin feel like a break in its continuity;

FIG. 1.—Multiple incisions over internal saphenous, and one lateral.

while here and there they lie so near the surface that they seem to be covered with little more than epithelium. The deep veins of the leg may be affected as well as the superficial ones. If the dilation goes on to a still greater degree a distinct, thin walled sac filled with fluid blood is formed.

As a result of the dilation many of the valves become insufficient. This can be tested in the following manner: After the veins of the lower extremities have been emptied by elevation of the foot and stroking the limb toward the body, the thumb is placed upon the main saphenous trunk, and the patient is directed to stand. The varicose veins will fill slowly and only to a moderate degree. The moment the thumb is removed the column of venous blood falling into them from above instantly distends them to their fullest capacity if the valves are incompetent. Such are the conditions of simple varicosity. Sooner or later one or more complications are likely to arise, such as thrombosis, rupture, phlebitis, oedema, eczema, and ulcer.

**Complications.**—Thrombosis may occur in dilated veins of the leg, exactly as it may occur in the dilated vein of an external hæmorrhoid. It is accompanied by a good deal of pain and tenderness, by slight redness, and by oedema plainly limited to the immediate vicinity of the vein involved. Thus if a not very tortuous vein is affected for a distance of five or six inches, its course can be accurately mapped out as an indurated strip about three fourths of an inch wide. If the vein is tortuous, the indurated area will have an irregular outline. The nutrition of the parts drained by varicose veins is often seriously affected, so that a wound may become infected. The result may be erysipelas, cellulitis, abscess, or suppurative thrombophlebitis, although the last mentioned condition is by no means common. When the vein lies near the surface it is easily ruptured by a blow from a sharp object, and, as there is little elastic tissue about the opening, the hæmorrhage is profuse and may be serious if it is not stopped by pressure or ligation. A fourth compli-

cation, more often seen in older individuals, is an extensive oedema. At first this is of the usual type, revealing itself by pitting on pressure; but after it has existed for many months the production of fibrous tissue may be sufficient to prevent much indentation on pressure. This condition may be due to other causes than varicosity of the veins; it greatly interferes with nutrition of the parts and especially with the repair of a chronic ulcer, whether varicose or not. Eczema is another complication due to an imperfect nutrition, which is apt to lead to ulcers starting in the small scratches made by the patient in the vain attempt to relieve himself from the intolerable itching.

Not every ulcer occurring in a patient whose veins are varicose is to be attributed to such varicosity. A long standing ulcer of the leg of a nonmalignant, nonsyphilitic, nontuberculous character is better spoken of as a chronic ulcer. It may be the direct or indirect result of varicose veins, but it may also be due to traumatism or eczema or oedema or anaemia. It is misleading to call all such ulcers varicose ulcers. They are all due to poor local nutrition, of which varicosity of the veins is simply one cause. When varicose veins have existed for a considerable length of time there will often be noted a brown pigmentation of the skin, occurring more or less in patches, and due either to small subcutaneous ruptures of the venous radicles or to transudation of red blood cells through the dilated venous walls. In either case the blood pigment becomes permanently fixed in the fibrous tissue of the skin, giving it a characteristic yellow brown color.

**Symptoms.**—Varicose veins often give rise to no symptoms whatever. Such is apt to be the case in young and healthy persons, and also when the veins are dilated throughout a small area. The symptoms in uncomplicated cases are: A sense of weight and more or less dull aching relieved by elevation of the affected extremity. The symptoms of thrombosis are: Marked tenderness on pressure, acute local pain, which is considerably, but not wholly, relieved by a recumbent position, and a rise of temperature of one, two, or three degrees. The symptoms of

FIG. 2.—Same patient, left leg.

the inflammatory complications mentioned are such as accompany these processes wherever they occur in the body.

**Diagnosis.**—The diagnosis of varicose veins and of the different complications which I have enumerated is easy for any one who is able to recognize

the different forms of inflammation and ulceration. The inflamed strip of a varicose vein is broader than that of infection in a lymph vessel, and the overlying skin is not so red. A sharply localized varix can hardly be mistaken for any sort of a cystic growth, as it is so collapsible on pressure, refills slowly, and has less tension than most cysts. It does not pulsate like an aneurism.

*Treatment.*—Palliative treatment of uncomplicated

FIG. 3.—Showing incisions over internal saphenous and incision for collateral, on posterior portion of the leg.

varicose veins consists in attention to the general health; in the avoidance of such occupations and such clothing as tend to interfere with the venous flow; in the elevation of the feet as much as possible when the patient is sitting down, and in the wearing, during the day time, of an elastic bandage or stocking extending from the toes to the knee. Even though the varicose veins extend well into the thigh, firm compression of the leg will usually relieve the symptoms, and it is difficult to apply a stocking or bandage with comfort above the knee joint.

A woven elastic, cotton or silk web stocking costs from \$2.50 to \$8.00. Its advantages are the ease with which it may be applied and the firm pressure which it exerts when new. A thin white lisle thread stocking should be worn next to the skin to protect the elastic stocking from perspiration. With the best of care an elastic stocking loses its tone in a few months, so that the expense is no inconsiderable item for a poor person. Various kinds of elastic stockings have been devised, such as pure rubber, rubber webbing, cloth webbing, stockinette, etc., but nothing is more satisfactory than pure, coarse, white flannel cut on the bias in strips about three inches wide, a sufficient number of which are sewed together to make a bandage six or eight yards long. Such bandages can be washed and ironed as often as they become soiled, and they will last a long time. They should be applied before the patient gets up in the morning. In the beginning this is considerable trouble, as it is by no means easy to bandage one's own leg. But most patients soon learn to apply them in five or ten minutes, and many put them on as neatly as a professional could hope to do. No one who has once become accustomed to apply such bandages would willingly exchange them for an elastic stocking, since he can always regulate the pressure according to his own comfort, aside from the fact that they are cleaner and cheaper.

The radical treatment of varicose veins may be

(1) their multiple ligation, either subcutaneously or through short incisions; (2) the excision of portions or of the whole of the dilated veins; or (3) the double ligation of the saphenous vein at its entrance into the femoral. The injection of substances to produce clots in the veins

The method of treatment which the accompanying photographs show is an original operation so far as I have been able to ascertain, and my only object in reporting the procedure at this early date is to have the good or poor qualities thrashed out by the profession, because it is only with an abundance of clinical proof or postoperative results, good or bad, that any definite conclusions may be established. The operation consists of several short incisions starting about two and a half inches below the knee joint, or more definitely at a point directly over the internal saphenous vein, where two large laterals are generally to be found. Cutting down an inch or two in length, the lateral ligated and liberated, the main vein pulled up and pulled upon, and where the lateral is given off above or below I usually proceed upward, the skin will tighten, and with close observation will show a slight wrinkling. Having thus determined the lateral, another small incision is made. The lateral is liberated and the vein picked up; this step is proceeded with as far up as it seems expedient to go. The vein is tied both proximally and distally, and cut between the two ligatures; then going to the next opening lower down, pulling on the main trunk gradually till it gives way and comes out free in the opening, thus pulling through subsequent openings until the original opening is arrived at. Then the step of pulling, locating, and ligating the laterals below the original opening is done as described for locating and ligating the original opening. When you have proceeded as low as you wish you simply keep on pulling the vein through till the lowest opening is reached. When you have, by sev-

FIG. 4.—Showing incision above and below the knee joint. The large incision of the scar tissue from scar tissue.

eral small incisions, delivered the entire length of the vein intact, if any large collaterals need to be removed, and there are usually some. The same principle can be and is applied, as shown in photographs of those incisions away from the main vessel.

*Conclusions.*—What is alleged for the operation is this: It does not take so long to do the operation as it does with other operations where the vein is removed, that it is not so apt to become infected, and if one incision becomes infected it can be dealt with

more readily and without infecting the others. There is no scar tissue at the knee joint, thereby causing no pain nor limping while walking. There is practically no blood lost, especially none from the main vein; what little blood is lost is from the skin. Convalescence is much shorter, a week to ten days' time being sufficient for the patients to stay in bed; they should be up to work by the end of two weeks. But if it is a case where it was urgent for them to be back to business, three to five days would be sufficient for to stay in the hospital before returning to light work. The convalescence is painless and uneventful. The style of closure is either interrupted or continuous. I believe, however, that the continuous silk suture is the best closure.

1826 FIFTH AVENUE.

### A CASE OF SARCOMA OF THE KIDNEY.

By L. F. LA PIERRE,  
Norwich, Conn.

Sarcoma of the kidney is not a common disease. Many general practitioners of wide experience have seen only a few or no cases.

The case reported in this paper was diagnosed at autopsy, no symptoms relating to the kidney being noted during life.

About 80 per cent. of sarcoma of the kidney occur during the first four years of life.

The aetiology is unknown. There are often no symptoms until the tumor is considerably advanced. This early period is spoken of as the latent stage of the disease.

Tumor, hæmaturia, pain, and cachexia are the usual prominent symptoms. Later occur emaciation, irritability of the bladder, œdema, jaundice, indigestion, constipation, and dyspnoea. All writers agree that tumor is usually first noted and is the most constant symptom. Palpable tumor is found at some time during the disease in 96 per cent. of cases. It is usually discovered in the loin, but grows forward toward the median line.

Sometimes it is necessary to give an anæsthetic to palpate the growth, and it can be felt best by the bimanual method. These tumors give rise to a fullness, resistance, and roundness in the ilio-costal space. The surface depends upon the nature of the tumor. It may be lobulated, irregular, or smooth and firm. In the more malignant round celled forms it is so soft as to give the sense of fluctuation. It is movable, but attached posteriorly. The progress of the growth is often very rapid, so that it may fill the abdomen in a few months. When this stage is reached the abdomen may be greatly enlarged, and presents a peculiar appearance. The veins in the abdominal wall are distended, the bowels are pushed to one side toward the median line, except the colon, which remains in front of the tumor. The colon is sometimes so tensely distended with gas as to be dull on percussion. In this extreme condition the child stands like a pregnant woman.

One author states that tumor was present in 129 out of 133 cases; another in 61 out of 64 cases.

Hæmaturia is another important symptom, and occurs in about half of the cases. It occurs when the tumor has entered the pelvis of the kidney, is more profuse than in stone or tuberculosis, and is

observed, as a rule, at the beginning of the disease. It may be steady for months or remittent, and finally disappear altogether. The amount of blood passed may be large and profuse enough to cause death. Sometimes the blood is voided as clots, which show as moulds of the ureter or even the pelvis of the kidney.

It is stated that the hæmaturia is not diminished by rest in bed, as is the case with calculus. In some cases the amount of blood passed is small and is discovered only with the aid of a microscope. Seibert states that in nineteen out of fifty cases it was observed before the tumor. Certainly hæmaturia occurring in children under seven years of age should arouse strong suspicions of renal tumor.

Pain is often absent, is not characteristic, and is not influenced by movements or pressure. Renal colic is sometimes caused by coagula or pieces of tumor obstructing the ureter. In general the harder the growth the more severe the pain. In children the growths are usually soft, hence they are usually free from pain. The pain when present extends to the lower dorsal or lumbar region and down the thighs. This is due to the growth extending toward the spinal column.

Constitutional symptoms are rare until the tumor has attained a large size. Sometimes, however, as in the case which I report to-day, generalization may occur early, when a marked anæmia appears with rapid emaciation.

Pressure effects are dyspnoea, œdema of the lower extremities, vomiting, and indigestion.

The growth may soften and break down, rupturing into the colon, duodenum, or ureter through the peritonæum or abdominal wall.

Some cases present an irregular temperature after the growth is well advanced. They waste steadily, death finally taking place from exhaustion. Varicocele is a symptom in some cases, and is of little importance when on the left side, as it may be normal, but becomes suggestive when on the right side.

If the tumor is not removed early the patient is sure to die. He grows progressively weaker as the tumor increases in size. The duration is variously stated from three months to two years. Death has occurred within six weeks. The softer the tumor the more malignant its character, quicker the growth, and earlier the end.

As already stated, the presence of hæmaturia in a child under seven years of age is suggestive of tumor of the kidney. In early diagnosis lies the only hope of saving the child's life. In cases without hæmaturia the tumor is the first indication. Relatively small tumors can be palpated in children, because the subdiaphragmatic space is flat and small and the kidney less firmly fixed. The conditions to be considered in the diagnosis are tumors of the liver, ovary, spleen, retroperitoneal tumors, hydro-nephrosis, hæmophilia, tuberculosis, and stone.

The only treatment is surgical, and in an early diagnosis lies the only hope of saving the patient's life by operation.

The primary object of this paper was to report the following case:

The patient was a female child, fourteen months of age. Both parents were living in good health, and were descendants of old Connecticut families. The maternal grandmother died of tuberculosis, and the maternal great grand-

father committed suicide. Otherwise the family history was negative, there being no further history of tumor, insanity, or neurosis.

This child was one of three children, and was third in order of birth. Previous to the present illness she had always been in good health, being stronger and healthier than the other children.

February 11, 1907.—During the night the child had had

FIG. 1.—Secondary tumors.

a convulsion. A physician was called, and the usual treatment was administered.

February 12, 1907.—Two more convulsions to-day.

February 13, 1907.—Child appeared perfectly well.

February 14, 1907.—Child continued to be well, was strong and well physically; no convulsions since the 12th.

April 5, 1907.—The child was brought to physician's office to-day. It had continued to be well since previous note. To-day a slight swelling was noted about the outer canthus of the left eye, extending horizontally backward into the temporal region. Skin was discolored, and the swelling had the appearance of a bruise. There was no tenderness or pain. Temperature was normal. Left eyeball appeared slightly more prominent than the right. Child was contented, very well nourished, but somewhat anemic.

April 12, 1907.—The swelling as described increased steadily and fairly rapidly. Left eyeball had become more prominent. There was a marked swelling of the tissues covering the right alveolar process of the superior maxillary bone. These tissues were spongy and bled easily.

April 14, 1907.—Teeth in the last named mass became loose and were removed easily to-day. Temperature continued normal.

April 17, 1907.—All masses were rapidly increasing in size.

May 1, 1907.—Patient had been seen frequently during past two weeks, and both local and general condition had grown progressively worse. It was as follows: There was a marked exophthalmus of the left eyeball. The palpebral fissure was much increased. The conjunctiva was subject to an inflammatory process, and bled in a mucopurulent discharge. The cornea was steamy and opaque. The anterior chamber was partly filled with pus. The pupil was dilated and immobile. There was a saucer shaped mass, which extended from the outer canthus of the left eye posteriorly and horizontally. Upon palpation the mass was smooth, elastic, gave a distinct sense of fluctuation. Heat, redness, pain, and tenderness were not present. Both

cheeks were abnormally prominent, this being more marked upon the right side. This made the bridge of the nose appear depressed. The tissues covering the alveolar processes of the superior maxillary bone were greatly increased, especially upon the right side, the surface upon this side having already commenced to slough. The jaws cannot be closed, and saliva drools from the mouth. (See Figs. 1 and 2.)

Nourishment was taken greedily, but with difficulty. There were no enlarged glands, and nothing abnormal was noted in the chest or abdomen upon a rather careless examination. Temperature, 100° F. Child was failing physically, and was very pale and sallow; it was restless and fretful. The urine was not examined microscopically, but appeared normal. Examination of a stained blood smear was as follows: The red blood corpuscles were ring like, stained faintly, and in an irregular manner, showing a fairly well marked polychromophilia. In size there was also a marked variation, there being numerous very small and very large corpuscles.

May 4, 1907.—The various growths continued to increase in size since last seen. The child died from exhaustion to-day, after an illness of one month.

May 6, 1907.—Autopsy nineteen hours after death. Body of a fairly well developed, but poorly nourished child. In the left temporal region was noted an elongated tumor. Its anterior end was at the outer canthus of the left eye, and extended posteriorly in a horizontal direction. It was five and a half inches in length and two inches in width. The upper border was represented by a line drawn horizontally backward from the left eyebrow; the lower border by the zygoma and a line continued horizontally backward. In the region of both cheeks below the malar eminences were tumors the size of a plum. All of these tumors were soft, elastic, and when palpated gave a sense of fluctuation. The skin was freely movable over them, but they were

FIG. 2.—Secondary tumors.

loosely adherent to the bone. The skin over the tumors appeared normal. In the frontal region over the glabella a small almond shaped swelling was noted. In the mouth the tissues covering the alveoli and hard palate were enormously increased, the surface was doughy and friable, chape in some areas. This swelling was so extensive that the jaws could not be closed, and the tongue protruded.

Both eyes were exophthalmic, the swelling being more marked on the left eye. Anterior at least three quarters

inch anterior to its usual position. The palpebral fissure of the left eye was increased, and there was a mucopurulent discharge in the eye. There was a small opening one eighth inch long at the lower margin of the cornea. The anterior chamber was obliterated, the iris was in contact with the cornea and the pupil was widely dilated. The cornea was steaty in appearance. The upper lid of the right eye was ecchymotic, the pupil was moderately dilated. The remainder of the body showed nothing remarkable, except emaciation. The superficial lymphatic glands were not palpable in any situation.

Chest.—Both pleural cavities were free from fluid and there were no adhesions. Both lungs were crepitant throughout. The pleural surfaces of both lungs presented elevated areas one or two millimetres in height, and from a few millimetres to a centimetre in diameter. The larger of these areas were dark red in color externally, and smooth, the pleura glistening over them. On cut section they were dark red, soft, and easily scraped away with a knife.

The pericardial sack contained a small amount of clear fluid. The heart was in systole and presented nothing remarkable either externally or internally.

Upon removing the lungs there were noted ring like enlargements surrounding the ribs, each rib being involved to a varying extent. Upon examination these reddish masses were found to be under the parietal pleura and periosteum. They were dark red in color, soft, friable, and, although intimately adherent to the bone, were easily separated from it. They resembled the areas already described in the lungs.

The peritoneal cavity contained a small amount of clear fluid. The peritonæum appeared normal.

Liver.—Upon the surface of the liver were areas from a few millimetres to a centimetre in diameter slightly raised above the surface, presenting a glistening, dark red appearance. Upon section a few of these areas were noted scattered through the liver substance. They presented the same appearance already described in the lung.

Gallbladder was normal and filled with bile. The spleen and right kidney appeared normal upon the surface and cut section.

On the left side, in the region of the left kidney, was found a mass. This when dissected out was seen to be six inches in length and three and a half inches thick. The mass was soft and fluctuated on palpation. On cut section it was found to consist of the kidney which had become the seat of a new growth. The upper third of the kidney could be distinguished and was fairly normal in appearance. The remaining lower two thirds was so infiltrated with the growth that the kidney structure could not be discerned with the naked eye. The tumor mass contained a cyst which contained about two ounces of dark red, groudous fluid. The remaining mass was dark red in color, friable, of varying consistence, some portions being semifluid, while other areas were firmer. The whole tumor, however, was so soft that it did not support itself after section was made of it.

Head.—Incisions to open the head began posterior to the right ear, then upward across vertex to avoid incising tumor. The anterior portion of the scalp was then drawn forward over face, and it was noted that the scalp was not adherent to the tumor, or rather tumors, in any of their situations. The large sausage shaped mass upon the left side, already described partially, was found to consist of dark red, very friable tissue similar to that already described in other organs. This tumor was intimately adherent to the bone itself, the periosteum being raised over the tumor. The bone under the tumor was soft, friable, and porous.

In the region of the glabella another small mass was noted, also in the right temporal region one of considerable size, all being in consistency and relations to the skull similar.

The skull cap being removed, the dura was adherent, hence requiring incision and removal with it. Upon examination a mass three and a half inches long, three and a half inches wide and one and a half inches thick was noted external to the dura matter, but firmly adherent to it, and very firmly and intimately so to the adjacent bone opposite the mass already described on the left side externally.

The inner table bore nothing abnormal upon the surface, in open section except upon the left

hemisphere there was a depressed area, which was due to pressure from the tumor.

Scattered about the vault of the skull in the same relations to the dura and skull were smaller masses from the size of an almond to a walnut. At least one half of the area of the inner surface of the skull was covered with these masses.

The horizontal portion of the frontal bone with its periosteum, especially upon the left side, was extensively involved, the growth extending through into both orbits. The globes of both eyes on section were normal, the exophthalmus being produced by the growth of the tumor between periosteum and bone. The growth continued into the face, involving both antrums, superior and inferior maxillary bones. The nose and air passages were not involved. These secondary growths appeared to originate between the periosteum and bone, the tumor in all cases separating the two structures.

Microscopically a section of the kidney showed a reticulum which was scanty and partially supported large masses of blood and small round tumor cells. The reticulum was wholly incapable of furnishing proper support to the tumor cells, which were of the small round cell type, of fairly uniform size.

The secondary growths in the liver, lungs, ribs, and skull presented essentially the same structure, except there was less hæmorrhage throughout the specimens, and the reticulum was more prominent. The growths all showed fairly uniform, small round cells.

*Anatomical Diagnosis.*—Primary, round celled sarcoma of the kidney, with numerous metastatic growths in the skull, ribs, liver, and lungs. Compression of brain. Emaciation.

#### Conclusions.

I. Sarcoma of the kidney may exist without symptoms.

II. Generalization may occur early, before the kidney is greatly enlarged.

III. In this case the appearance of the anæmia and rapid loss of flesh was coincident with its generalization.

IV. In this case, had not a complete autopsy been performed, a correct diagnosis would not have been made.

#### THE CLINICAL SIGNIFICANCE OF McBURNLEY'S POINT.\*

BY ARNOLD STURMDORF, M. D.,  
New York.

In an article, On Appendicitis, published in the *New York Medical Journal*, December 21, 1889, Dr. McBurney wrote as follows:

The exact locality of the greatest sensitiveness to pressure has seemed to me to be usually one of importance.

Whatever may be the position of the healthy appendix as found in the dead house, and I am well aware that its position when uninfamed varies greatly, I have found in all my operations that it lay either thickened, shortened, or adherent very close to its attachment to the cæcum.

This, of course, must in the early stages of the disease determine the seat of greatest pain on pressure, and I believe that in every case the seat of greatest pain, determined by the pressure of one finger, has been exactly be-

\*Read before the Section in Surgery of the New York Academy of Medicine, December 6, 1890.

tween an inch and a half and two inches from the anterior superior spinous process of the ilium on a straight line drawn from that process to the umbilicus.

This may appear to be an affectation of accuracy, but as far as my experience goes, the observation is correct.

Thus announced, nearly twenty years ago, this diagnostic dictum, emanating so authoritatively and promulgated with such modest dogmatism, found unchallenged general acceptance, which continues to dominate clinical discrimination in abdominal disturbances to the present time.

Antedating the adoption of present day methods, the introduction of McBurney's point marks an epoch and a phase in the evolution of our mastery over appendicitis; nevertheless, while it served to blaze the path through the mazes of earlier controversies, it has proved an equally potent factor in leading to error and fruitless mutilation.

"History repeats itself": the accepted dogma of yesterday becomes tradition to-day and merges slowly into the obsolete of to-morrow.

McBurney's point, vested with pathognomonic dignity for almost two decades, must be relegated to the humble rank of a possible contributory diagnostic factor.

The pathognomonic validity of a given clinical sign is proportionate to its constancy in the given condition; this essential postulate is not fulfilled by McBurney's point.

While it is true to-day, as it was twenty years ago, that a typical McBurney point may be present in a typical appendicitis, it is equally true that appendicitis may exist in the absence of a McBurney point, and, most important, a typical McBurney point may be present in the absence of appendical involvement.

To speak concisely, there are three groups of cases in which operative or post mortem findings bear directly upon the point under consideration.

In the first group, a frank appendicitis tends to substantiate the pathognomonic validity of an existing McBurney point.

The second group embraces two types of appendical lesion—one, characterized by a most rapidly fatal tendency; the other, projecting all of its symptoms upon the upper digestive tract, while neither type manifests a McBurney point during any stage of its progress.

The third group, the most extensive of the three, consists of a heterogeneous class of cases that present a typical McBurney point in the absence of any appendical involvement whatsoever.

Any attempt to establish a clinical sign as an index for operative intervention should be based upon a thorough understanding of the normal or pathological physiology of its production.

Unfortunately, such fundamental factors relating to our knowledge of the sensory manifestations in abdominal disorders are still undetermined; nevertheless, there is much information of an empirical nature, gleaned from the observations of Ross, MacKenzie, Head, and others—on the distribution and character of the pain in visceral disease—that has not found general clinical utilization.

It would lead beyond the scope of the present communication to attempt a detailed consideration of these observations, consequently their fundamental bearings only will be touched upon.

Ross contended that in visceral disturbances pain or tenderness radiated along the distribution of the somatic nerves, springing from that segment of the cord which supplies the sympathetic fibres to the affected viscus.

Amplifying Ross's work, MacKenzie and Head defined certain areas, each of which, it is stated, corresponds to the cutaneous terminals of the pain fibres, springing from that cord segment involved by the disturbed viscus.

Whatever may be confirmed or refuted, in the theory and practical application of these observations, they have established one clinical fact beyond controversy, namely, that any given point of pain may be either the *direct expression* of a contiguous disturbance, or the *transmitted manifestation* of a distant lesion.

In other words, an existing McBurney point may represent the *direct pain focus* of a disturbance within its own area or the *reflected pain focus* of a distant lesion.

Thus far, then, we find in McBurney's point simply a clinical sign susceptible of two interpretations and the problem of its distinctive definition naturally presents itself.

A comparison of Head's instructions for the demonstration of his "pain points," with those given by McBurney, reveals two widely different methods, eliciting two distinct and characteristic phases of one and the same subjective sign.

Thus, Head insists upon the gentlest possible tactile exploration of the cutaneous surface, specifying that "the examination must be carried out with a round pin head of such a size that it proves obviously blunt to all parts of one's own face, and used in exactly the same manner as in testing for analgesia."

Compare this most delicate palpatory excursion of a blunt pin head over the cutaneous surface with "the direct pressure of one finger," according to McBurney, and it follows that Head's method can elicit superficial areas of pain only, or—more correctly speaking—areas of superficial hyperalgesia, while McBurney's method must of necessity elicit indiscriminately both superficial and deep seated pain points at the same time according to the intensity of the pressure exerted.

Combining these two methods, by utilizing the one as complementary to the other, it will be found that there exist two McBurney's points, one superficial and the other deep.

The superficial pain point, which for practical purposes we will term the pseudo McBurney's point, presents all the characteristics of Head's so called "referred pain points," indicating a disturbance beyond the limits of their own area, while the deep or direct pain point, when present, will be found to indicate a local disturbance within its immediate vicinity.

It is not only this variation in the level of the two points, but also the marked contrast exhibited in the character and radiation of the pain, as well as certain differences in the response of the local reflexes, which offer distinctive criteria, distinguishing the indirect from the direct pain focus.

An indirect or transmitted pain focus or pseudo McBurney's point, as elicited by Head's method of

exploration, is practically a circumscribed area of cutaneous hyperæsthesia, and, like all such areas, it is characterized by heightened superficial reflexes in the presence of apparently normal deep reflexes; by the simultaneous existence of concomitant pain points, radiating backward and upward toward the spine, most marked over the bony prominences encountered in tracing the course of the involved nerve trunks to their exit from the cord.

In the presence of the direct or deep pain focus, on the other hand, the skin and subcutaneous tissues may be pinched between finger and thumb without eliciting any undue sensitiveness; the deep muscle reflexes are exaggerated, even to the point of tonic contraction; concomitant pains, when present, radiate *downward* along the anterior crural nerves and into the perinæum, but never upward and backward.

As noted before, the cases in which operative or post mortem findings bear directly upon the clinical significance of McBurney's point resolve themselves naturally into three groups.

Applying the foregoing observations to the first group enumerated, namely, the cases in which a distinct involvement of the appendix would tend to substantiate the pathognomonic significance of McBurney's point, the following is to be noted:

There will be found no superficial area of hyperæsthesia, according to Head's method, while deep pressure, according to McBurney, will elicit a focus of pain.

There will be present the familiar accompaniments, both local and general, of a deep seated inflammatory process.

Blumberg's sign is demonstrable in all these cases—that is, when the appendicular inflammation is unaccompanied by peritonitis, the deep pain focus in McBurney's area alone is manifest; with beginning peritonitis, the recoil of the abdominal wall following the sudden withdrawal of the examining finger will prove more painful than the original digital pressure.

The cases in this group represent the acute form of the adhesive, exudative, or suppurative types of appendicular inflammation, *without* perforation or gangrene, which latter conditions are found among the cases of the second group.

This second group embraces two forms of the disease, neither of which, during any stage of their progress, present any distinct focus of pain in McBurney's area.

The first form represents the most rapidly fatal types of appendicular lesion, presenting themselves clinically as unfocalizable forms of profound general sepsis; the second form, on the other hand, manifests but mild disturbances of the upper digestive tract; this latter is the form described by Ewald as "appendicitis larvata, or masked appendicitis."

In the third group, the most protean, extensive, and, from the present point, the most important of the three, are found acute and chronic disturbances of every degree and many kinds, linked by an existing McBurney's point over a normal appendix.

It is in this group that operative artefacts, resulting from clamp and ligature applied to an unoffending appendix, supply a pathological consola-

tion for misdirected surgical effort, while the true source of the disturbance lurks somewhere between the thorax and perinæum, anywhere but in the appendix.

In illustration it is but necessary to recall the abdominal symptoms of thoracic disease, the distension and the pain over the appendicular region resulting from right sided pleurisy, empyæma, and pneumonia, McBurney's point frequently presenting itself, while the physical signs of the thoracic disturbance are still in abeyance.

Our understanding of the sensory manifestations of visceral disorders is still incomplete; nevertheless, it is fairly well established that the abdominal organs are devoid of direct pain sense, and that the pain of visceral disturbance is located in various layers of the abdominal parietes.

According to Ramstroem, the lower intercostal nerves and the lumbar plexus subserve the function of pain conduction in visceral disorders.

These nerves, after supplying sensory fibres to the superficial layers of the abdominal parietes, intersect and combine to form a complicated ramifying network between the internal oblique and transversales muscles, dipping down at the edge of the rectus sheath, they terminate in the parietal peritoneum.

In this arrangement all sensory manifestations within the appendical area are dominated by the iliohypogastric and ilioinguinal terminals, and when the distribution, ramifications, and anastomoses of these nerves is recalled, it will become apparent that McBurney's point, superficial or deep, must be interpreted clinically simply as a focus, upon which may be projected the sensory manifestations resulting from disorders in any of the organs or tissues of the right thorax or abdomen.

The greater the distance between an existing McBurney point and its causative disturbance, the more superficial the pain focus, and, conversely, the more superficial this pain focus the more certainty of its indicating a distant lesion and a normal appendix.

The comparative safety of operating in a quiescent or chronic stage of appendicular inflammation has tended probably more than any other factor to inculcate a reckless confidence in the surgical indications of an existing McBurney's point; there are those who in other conditions exhaust every means to establish proper operative indications, yet accept the presence of McBurney's point as sufficient justification for appendectomy.

The present communication is intended to be suggestive rather than exhaustive, and, for obvious reasons, a detailed enumeration of the manifold conditions that may simulate a McBurney point would be out of place.

The relation of prolapsed right kidney to the condition under consideration has been emphasized by the writer on several other occasions—the other nephritic, like the ureteral, the gallbladder; the gynecological and genitourinary conditions that naturally force themselves upon our consideration in connection with this theme are too well known to surgeons to require more than mention here.

There is one topic, however, the essential relations of which to our theme warrants more than

allusion, namely, the rehabilitation of primary typhlitis, acute and chronic.

In the *Annals of Surgery* for June, 1907, C. A. McWilliams, treating of the subject of Typhlitis without Appendicitis, reviews the recorded cases of the past seven years. He admits that primary typhlitis is rare in comparison with appendicitis, but feels justified from the evidence which he has collected in holding that primary acute and chronic typhlitis may occur independently of appendicitis, dysentery, tuberculosis, actinomycosis, or cancer, and that it may be either idiopathic in origin or due to coprostasis. Numerous autopsy reports and findings at operations have confirmed him in this opinion. The disease in the cæcum may go on to ulceration and perforation, with the formation of a perityphlitic abscess or general peritonitis, while the appendix remains normal. Howard Kelly alone has reported fourteen cases presenting primary lesions in the cæcum, the appendix being normal.

It is well to bear in mind that there is such a disease as primary typhlitis, especially when dealing with patients who have been operated upon for chronic appendicitis and who suffer from a recurrence of symptoms. This recurrence may be due to attacks of typhlitis. Haberer reports ninety-six interval operations for appendicitis, in only fifty of which were the symptoms entirely relieved by the operation; forty patients continued to have more or less marked symptoms, such as obstinate constipation and severe pain, from which they had suffered prior to operation.

The aim of the humblest scientific effort is the elucidation of fact. The effort frequently entails years of multiplied tasks. The facts gleaned may usually be rendered in a few words. The foregoing is a sketchy outline of such an effort, based upon two hundred and eight cases observed in public and private service during a period of three years.

#### PREVENTION OF THE NERVOUS AND MENTAL DISORDERS INCIDENT TO SCHOOL LIFE.\*

By J. HALL PLEASANTS, M. D.,  
Baltimore.

Instructor in Medicine, Johns Hopkins University, Assistant Professor of Medicine, University of Maryland, Baltimore, Medical Director of School.

The prevention of those disturbances of the nervous system and of the mind incident to school life is not a problem which the physician can approach single handed, but rather hand in hand with the educator. *Medical inspection* of the schools can only be looked upon as a stepping stone to a more efficient

and comprehensive system of *hygienic supervision* of our entire system of education, if real and lasting results in the betterment of the race are to be hoped for.

Within the past decade great changes in our educational system have been made, changes which mean much for the well being of the child, both mental and physical, but much remains to be done, and glaring defects vitally affecting the child still exist in this as in other communities. Home conditions are even worse as regards physical hygiene in very many cases. The only way we can hope to improve this is by education. The schools have thus a double function to perform, they should be practical examples of the best possible hygienic conditions not only for their direct effect upon the health of the child, but as educational influences which future fathers and mothers will profit by in the homes of the next generation.

School life may be said to begin at five years of age and to extend to about eighteen. It thus covers the latter years of childhood and the greater part of adolescence, those periods of human life when mind and body are passing through their most formative stage, and are most responsive to mental and physical environment. The vast majority of the disorders of mind and body incident to this period are directly attributable to an almost universal disregard of the simplest rules of mental hygiene in the school and of physical hygiene in both the school and the home. As important as are the immediate effects, the more remote results of this disregard are traceable throughout life. The factors most influencing the physical and mental welfare of the child in school—for these can in no wise be separated—are, a, the age at which school attendance begins; b, the mental demands made upon the child in study; c, the opportunities afforded for necessary fresh air and physical exercise; and, finally, d, the hygienic condition of the school building and its surroundings.

The age at which school attendance should begin has been much discussed. Individuals vary slightly in precocity, but it may safely be said that no child should enter school, as now understood, under eight years, and only exceptionally should school attendance begin under ten. Only too well do I realize the derision with which this statement will be generally met, on the ground that it is absolutely impracticable. Let us look for a moment at the grounds upon which these limits are based.

Life up to the eighth or ninth year is largely an animal existence. Every instinct demands light, air, and freedom. Incessant muscular activity resents all physical restraint. Anabolism is most active, building up brain and muscle for the demands of the future. The senses are becoming more and more alert, and memory increasingly retentive. An awakening interest in the world of nature rivets and develops attention. All objects in nature offer a fascinating interest, but as yet the mind is but ill prepared for reason or study. *Physical education* is in striking contrast to physical endurance, and attention, if easily aroused, is as easily exhausted. Physical and mental response to good air, sunlight, food, and physical exercise is at its height, and at its best in this period. And how in these responsive demands of nature met! At times of boy or girl we cut off our children from fresh air and sunshine,

\*Read before the American Association of Pediatricians at the Medical and Chiropractic Institute, at Philadelphia, October 1907.

and confine them for hours in overcrowded, dusty, overheated, underventilated, often badly lighted rooms, shut off the safety valve of physical activity, and force their growing brains to undertake mental processes of which their degree of development renders them incapable, and make sustained demands upon the attention, which it is not able to endure without damaging strain. And we call this education.

Now for the remedy. The proper place for every child is the country, or as near true country conditions as possible, and this is especially true of the age we are now considering. No child under eight, or, better, ten, should attend the city school, as it is now understood, for task study. The child fortunate enough to live a healthy, outdoor, animal life in the country, with no definite study routine, but encouraged by a conscientious effort on the part of parent or nurse to take a lively interest in rational play and nature studies, such as gardening and the like, thus developing attention, orderliness, and the power of observation, this child is receiving the best possible training for future study and progress. When placed in school, contrary to general belief, progress will be so rapid and easy it will be seen within a few years no time has been really lost, and that much mental and physical capital has been gained. But, of course, such ideal conditions are only for the favored few. The great bulk of the population is crowded into cities and towns, with indifferent or poor home surroundings, and many parents forced by our industrial system to spend much of their time away from home. The school for these parents is as much a free nursery as a source of education. Circumstances require, and poor home surroundings make it desirable, that the community should, therefore, provide for the care of city children five years old and over. The kindergarten was at one time supposed to be the solution of the problem, but has not proved so. In the first place, the kindergarten, as generally found, was only adapted to the very young children—four or five years old—and too soon were the poor unfortunates pushed into the miserable old competitive, conventional, leveling, task study system. Moreover, the kindergarten classes are almost universally held in the ordinary public school building. What is needed is a radical departure from all this. Special schools, kindergarten, or whatever title you choose to give them, should be established in the suburbs or parks, where nature studies, or, better, nature observation, could be followed. The classes should invariably be held out of doors except in severe weather; systematized play and exercise in natural surroundings should predominate over assigned tasks, and no attempt made to educate the child under eight, as is now understood, in much of the graded work of the modern elementary schools. What we require are systematized playgrounds in the broadest sense in connection with rational kindergarten work, and the next development in the playground movement, now so rapidly gaining momentum, will probably be along these lines. Nor is the possibility of suburban or park schools for older children as well as kindergartens a mere dream. In Baltimore the development of suburban growth and the extension of the park system make the scheme entirely practical as regards new schools. Plenty of elbow room should be pro-

vided along these lines. In the case of the children in the denser centres of population, free transportation on the street cars to schools more favorably situated should be provided by the city. At first sight this may seem impractical, but a moment's reflection will show that such a plan does not complicate the already serious congestion of traffic during the morning and late afternoon hours, as the school traffic would be in exactly the opposite direction to the ordinary rush. No doubt the street railway company would be only too glad to fill their returning half empty cars at a much reduced rate through the sale of special school tickets.

As regards the effect of the *mental demands* made upon the child of suitable school age by the requirements of the present system of education, I speak with some hesitation. Much has been done and much is being done by the thoughtful educator of this and other communities to work out a rational system. The brake upon progress lies more in slavish adherence to the old system and blind ignorance on the part of parents and the community, than upon progressive educators, who see light, but are hampered at every turn. Before we can hope to educate the children rationally we must awaken the parents to the vital importance of a change.

Shorter hours of classroom work, more frequent recesses, variety in study to maintain interest, elective work for the older children, avoidance of home study, freedom from competitive work, and brisk, capable, young teachers do much to lessen the mental wear and tear with its train of nervous and physical evils. The child must be educated as an individual, and education not used as a means to grind individuality to the dead level of a school grade.

The opportunities afforded for *physical exercise* at present are notoriously insufficient in nearly all the public schools of this city. Such work should be in the hands of professional physical directors. Gymnasias properly equipped are a valuable adjunct, especially for the older children and in inclement weather, but in general, exercise should be taken out of doors in playground or athletic field. This is not possible in our present city schools with their small yards, but must be found in the parks or suburbs. The younger children can get their exercise in regulated games in the playground, and by movements under order. Rhythmic movements are not advisable. In contrast we find, even in our new suburban schools, a small, high fenced bricked yard, in which the children are turned helter skelter for fifteen or twenty minutes, with scarcely elbow room, to play, fight, or freeze as the case may be—and this is the physical exercise which we offer all sizes, ages, sexes, and constitutions to repair the physical and mental waste our system of education entails, and to help strengthen body and mind for the tasks of to-morrow. Of what advantage is our boasted knowledge of the cause of disease and the so called preventive medicine of to-day if we do not apply it? The Greeks understood the secret of a healthy mind in a healthy body infinitely better twenty centuries ago.

*The hygiene of the present school buildings*, or, rather, the lack of it, is largely responsible for many of the physical and mental defects of the children. So much has been written of the deplorable condition of many of the older city schools that repetition

here is unnecessary. The buildings are overcrowded, the air space of the room insufficient, ventilation simply nonexistent, rooms overheated by closed coal stoves, badly lighted, with improper wall coloring, desks ill fitting and not adjusted to the size of the child, toilet facilities unhygienic and inadequate—these go to make up a picture in many schools. Apart from the direct effect of all this upon the health, what ideals can we expect from children brought up in such surroundings. I can bring no more convincing argument of the effect upon health of such conditions than to cite the result of a recent inspection of a school annex situated over a paint shop. The children were overcrowded in small, low pitched rooms, heated by red hot stoves, and without ventilation. These children showed a proportion of enlarged tonsils of 24 per cent., as compared with 11 per cent. among children of the same age and class in a new school one block away. If our civilization compels us to remove our children from the fresh air and sunshine when their bodies most require both, to deprive them of the natural outlet to their energy through unrestricted physical exercise, and to force their unstable and delicate brains to undertake mental tasks, which, under most favorable circumstances, involve great strain upon mind and body, it is certainly our duty to insist that the conditions under which they are housed should be exemplary.

In the years of childhood we sow most of the seeds of physical and nervous deterioration. In the years of puberty and early adolescence this seed, which in childhood has already sprouted, and in some cases grown, now springs up and flourishes with peculiar vigor, and we begin to gather our crop of neuroses or actual organic degenerations from a body and mind rendered especially unstable by the physiological demands of this critical period of life. Dementia præcox, hysteria, neurasthenia, the neuroses, the psychoses, chorea, the tics and habit spasms, and impaired mental power are but a few. Apart from physical defects, which act as a predisposing handicap, many of these conditions owe their immediate onset to overstudy, examinations, and the attempt to keep up with the strict grade system, which tries to fit the child to the task and not the task to the child. Many of these children have come into the world with the additional handicap of bad heredity, and even under the best conditions have a tendency to drop on the march.

The physical defects responsible for a *diseased or disordered nervous system* as seen in school children are often of a character which can be remedied or improved. Their prompt recognition and treatment is, therefore, all important.

*Malnutrition* probably stands at the head as a cause of functional and organic nervous disease. Very many of the children are insufficiently and improperly fed. This at once brings up the question of feeding, not only of children of school age, but of these same children in infancy, for we must begin at the beginning. Careful observation leads me to believe that we are less frequently dealing with actual inability through poverty to supply sufficient food than with dense ignorance as to what kind of food should be given. In our work of inspection we use the school nurse as an educational factor. She visits the homes of such patients, and as far as pos-

sible makes practical dietetic suggestions to parents.

*Eyestrain* probably ranks next in importance. Our Baltimore figures are incomplete, as a routine Snelling test is not made in all cases. As a prophylaxis to the train of nervous disorders incident to eyestrain, the number of inspectors should be increased from five to at least fifteen. Each inspector now has about 13,000 children under his care, and the impossibility of making a careful examination of the eye under the circumstances is evident. I am not in favor of the teacher making examinations of the eye, as has been suggested. Few are qualified to do so intelligently, and the mistakes will discredit the entire system. Besides, they are already overworked. Notwithstanding the incompleteness of this branch of inspection as now done, very many cases are recognized and corrected. When examination shows serious error to exist, children should not be allowed to attend school until correction is made. This at once brings up the question, Should the city supply glasses as it now supplies school books, some parents protesting that they cannot afford to buy glasses for their children? My feeling is that the city should not do so, for if supplied to one they must be supplied to all. It seems better to rely upon organized charitable agencies in such cases, as savoring less of paternalism. While correction of existing defects is absolutely necessary, much more important is the prevention of eye disease by improved lighting conditions and properly adjusted desks. In some of the older schools the rooms are both insufficiently and improperly lighted. In few of the schools is the question of wall covering considered at all. The conditions in some schools beggar description. The practice of fitting a five year old child and a long legged boy to the same kind of desk is almost universal in the older schools. Not only ocular disease, but lateral curvature, with their train of symptoms and deformities are thus combined. A very practical difficulty is encountered in some cases in compelling the children to wear the glasses, when supplied, as much as they should.

*Adenoids* are responsible for a definite train of nervous disorders. The difficulty lies in securing removal after parents have been notified of their presence. In New York, if, in aggravated cases, parents do not heed the notices of the inspectors, compulsory removal in school is performed. Up to the present time this has not been possible in Baltimore. Our figures vary, but in two old schools recently examined by me there were 207 cases of adenoids among 840 children of all grades. I should insist upon removal in aggravated cases, referring those in dispute to the arbitration of a specialist in the employ of the health department. A very large proportion of backward children suffer from adenoids. This I feel to be due to several causes, the direct effect of the condition upon the body and mind, the frequency of "colds" and catarrhal disorders necessitating absence from school, and the effect of deafness resulting from Eustachian disease upon the progress of the child. Some of the most striking cases of rapid mental and physical improvement, with astonishing progress in study, are seen after operation for adenoids.

*Enlarged tonsils*, unless associated with adenoids, frequently do not give rise to symptoms. If much enlarged, however, or if there is a history of recur-

rent acute attacks of tonsilitis, parents are notified that they should be removed. Here again comes in the difficulty of enforcing our recommendations. The greatest obstacle to the proper operative treatment of both enlarged tonsils and adenoids is the ignorance or indifference of the average family physician in certain sections, who usually prescribe a gargle, and laughingly tell the parents that the condition is not serious. My school experience has somewhat modified my views of the significance of tonsillar hypertrophy. A very large proportion of cases apparently are not subject to attacks of acute tonsilitis. On the other hand, hypertrophy frequently seems to be a response by the body to bad air and unhygienic surroundings. The figures already referred to, in which, under such circumstances, the percentage of enlargement was more than twice as great as in children better housed, suggest that after all hypertrophy may be in one sense a conservative process. It seems probable that enlarged tonsils *per se* play a small part in the production of physical or mental disorders, and that when coexistent, as they so often are, with adenoids and such conditions as malnutrition, adenitis, backwardness, etc., may be an associated symptom rather than the underlying cause.

*Deafness* among school children is not uncommon, but it is interesting to note how frequently it is overlooked by the teacher, and the resultant backwardness of the child attributed to inattention or impaired mentality. Several pathetic cases have been set right when the teacher realized the mistake and the child was more favorably placed. The frequency of this condition can be lessened by better control of epidemics of scarlet fever and measles. The treatment of such cases in the rapidly building hospital for contagious diseases, where the services of experts can be at once obtained in cases of otitis media, should do much to lessen ear disease. The compulsory removal of adenoids will also do much. Wax is a frequent and often overlooked cause of deafness in children.

*Epilepsy* in the schools presents a difficult problem. Until very recently epileptics were admitted to the general classes. The demoralizing effect not only upon the rest of the class, but upon the unfortunate victim of recurrent convulsions in school, can be imagined. An attempt has recently been made to segregate the epileptics in special classes, but this presents practical difficulties. It has been definitely shown that the proper way to manage the disease among the poor is to establish colonies in the country, where special education and suitable occupation can be provided. A crying need in this community is provision by the State for such an establishment.

Recent investigation of the physical condition of the mentally deficient, the incorrigibles, and the truants has thrown much light upon the proper treatment of such cases. With the idiots and imbeciles we are not now concerned. This condition is, of course, incurable, although much can be done in special institutions by proper training to render them more or less useful and happy. It is a stigma upon the State that totally inadequate provision is made for their care, although public opinion is so aroused that something will doubtless be done by the next legislature.

What concerns us more in this connection is the

problem of how to better the condition of those children who are mentally below par. It has been definitely shown that a very large proportion of such children suffer from physical defects, especially eye-strain, deafness, adenoids, and malnutrition, and that when these conditions are corrected or improved the child at once begins to make more rapid progress in study. The New York figures prove this without question. There still remains, however, a large number of backward and deficient children whose condition is not dependent upon physical disease, but an inherited inferior mentality. Special schools for all such children are impracticable, nor are they desirable. It seems best for such to mingle with normal children in study and at play. To rub up against others better endowed seems stimulating and of distinct benefit. In class work, however, such children must be taught individually in small, ungraded classes. For this purpose teachers of the highest type are needed. I know of no work which requires a higher order of tact and intelligence than the teaching of the so called ungraded classes. The importance of getting the most out of such children and encouraging selfreliance is not only humanitarian, but economical. If placed in special schools and separated from other children they fail to develop selfreliance, and when turned adrift on the world eventually become public charges.

The very high percentage of physical defects found among *truants* and *incorrigibles* has thrown much light upon the causes of truancy. It has been found that the great majority of such cases suffer from adenoids, imperfect vision, deafness, or other defects. Such children have a tendency to fall back in their studies, become sensitive or mortified, then defiant, and finally drop into truancy. The results in the so called parental schools where such children have received proper moral and physical treatment have been most gratifying. Of course, it is not meant that all cases can be explained on this ground, for many are recruited from the congenitally defective and degenerate.

And, finally, a word in regard to that indefinite but increasing class of children to whom only the term *nervous* can be applied. It is begging the question to consider their condition as an inevitable result of our civilization, and to sit by fatalistically and allow the army of adult weaklings, neurasthenics, psychasthenics, and insane to be recruited without protest. The curse of heredity can only be combated by environment and education.

We have in the school the opportunity to bring about better things, if by wise medical supervision of education we make the school an object lesson of practical hygiene, and direct the teaching of the school so as to extend the knowledge of healthful living. In this way not only can disorders of the mind and of the nervous system incident to school life be controlled, but the mental and physical welfare of the race can also be placed on a higher plane.

In conclusion, let me summarize certain leading points:

1. Children under eight, or, better, ten, should not attend school if country life and parental attention are possible.
2. City children between five and eight should be placed in kindergartens situated in parks or suburbs where nature study and systematized play and light

ungraded objective work in the open air can be carried out.

3. Schools for older children should be gradually removed to the parks or suburbs and equipped with playgrounds and physical directors.

4. Overstudy and competition among the more ambitious pupils should be prevented, and the leveling of the child to the grade avoided.

5. The hygienic condition of the schools should be maintained at the highest efficiency, both for the effect upon the child's health and as educational object lessons.

6. Physical defects (usually remediable) at the basis of many mental and nervous disorders are principally:

a. Malnutrition, to be combated at present largely by the educational influence of the school nurse.

b. Eyestrain, if of advanced grade or if productive of symptoms, to be corrected, and the wearing of glasses made compulsory.

c. Adenoids and enlarged tonsils to be removed; in neglected cases the health department should have power to enforce removal.

d. Deafness to be prevented by the better control of epidemics and removal of adenoids.

7. Epileptics to be placed in separate schools, or, better, in rural colonies.

8. The condition of many so called mental deficiencies improved or cured by correction of physical defects.

9. Truancy and incorrigibility in many cases due to the handicap upon mental work of physical defects.

10. Education of idiots, imbeciles, and the feeble minded, as far as they are capable, in special institutions maintained by the State.

11. The education of children slightly below par mentally in small ungraded classes in the public schools.

12. Substitution of a broad medical supervision over education by a board of physicians and educators instead of mere medical inspection.

16 WEST CHASE STREET.

## THE PSYCHIC TREATMENT OF NERVOUS DISEASES FROM A PRACTICAL STANDPOINT.\*

BY CLEMENT A. PENROSE, M. D.,  
Baltimore.

Since the address of the Rev. Ellwood Worcester and Dr. Coriat, of Boston, Mass., before the Hopkins Medical Society, May 20, 1907, it has seemed expedient that the psychic treatment of patients should be treated from the standpoint of the general practitioner on its practical and everyday side. There is danger that a man not especially trained in observation and the study of psychology might, possibly, take an extreme view of these methods and the facts presented to him on that night and in the literature of the present day.

In the first place, I take exception to the statement that the mass of people who have become interested in psychotherapy have been really driven into this by the neglect of the profession at large

in adopting such treatments. I doubt, indeed, if there is any suggestion more potent than the influence of the family physician, or the simple administration of a remedy by one in whom we have such confidence. I believe that the medical profession at large have used and uses suggestive therapeutics more than is generally known and as much as they have dared, owing to the prejudice against such methods by many patients. That a training along these lines is most essential I admit, but whether strictly scientific or no, is questionable when we see it recommended that such cases be turned over for treatment, and apparently successful treatment, to men who have not had a scientific training.

Leaving this point for the moment, the question of chief importance is, Why this growing need for psychic treatment in this country? I hope to show that this is not due to the neglect of the doctors, but rather an increase of a certain degenerate type of mind, fast spreading over our land. We have in this country every reason for the production of a class or type of people who, without entering into any scientific classification, I shall group under the general heading of the "mind weary"; a reaction, as it were, against the strain and turmoil, the ambition and excessive nerve restlessness of the present day. I believe that I can safely say there is scarcely a psychoneurosis that would not come under this general heading. There is no better class of people in which to study this type than in those who are led to join the Christian Science Church. This is a type that has lost the desire to think for themselves, or, if they must do so, do not care to use the mind in a way that is hurtful or fatiguing. How many thousands of these poor mind weary wretches are on the lookout for some simple, plausible, easy solution of the problems of life that will cut them out of all its responsibility! What wonder that a mother, worn out by numerous cares, should adopt the theory in which she, smiling over her sick child, can say that "all pain is error, there is no such thing as pain," and go back to her bed, free from all the worries of motherhood and safe in the consciousness of her right doing. People of this type will accept anything without argument, proof, or consideration. As an illustration: An able man and thinker, a personal friend and patient of mine, attended a meeting at the Mother Church of the Christian Scientists in Boston some time ago. He related to me a number of the experiences given at that meeting, two of which I will repeat, as well as my memory allows, as an example of what I am endeavoring to prove.

The first experience cited by one of the members of the congregation was as follows: A man on the street was run over by a heavy furniture van, and suffered a fracture of the thigh, the powdered bone from which could be seen sprinkled on the streets. While some one was running for a doctor, another for an ambulance, etc., a majestic figure appeared, namely, Mrs. Eddy, who waved her hand over the man, and in a moment he was healed, arose, and walked away.

The second experience was told about a little girl of three years, who, while sewing, drove a needle through the thumb and base of the thumb, and the

\*Based before the Johns Hopkins Hospital Medical Society, Oct. 1, 1907.

left hand. The mother withdrew this, quoted a few words from *Science and Health*, the child stopped crying, and the wound immediately healed.

My friend, being a broad minded and intelligent man, appreciated at once the utter impossibility of these two experiences, the powdering of raw bone, for instance, and the ability of a child of three to force a needle through the bone of the thumb. He looked around upon the faces of the fashionable, well dressed and better class audience to find a single dissenting look or even a gesture of incredulity, but to his surprise these experiences, with a dozen more equally ridiculous, were accepted by all, as a matter of fact, and beyond question. He asked me for an explanation of this, as he called it, curious phenomenon. I replied, as I would here, it is because they belong to a mind weary class, who care not to think or investigate; they will accept anything rather than take the trouble to argue it down or deny it.

I only bring in these cases to show why it does not seem to me especially requisite that a general practitioner must have a technical training in psychology in order to influence such people. Let us compare the mind weary man or woman, toiling up the road of life, to a person walking up a hill with a heavy burden on his back. We can lessen this burden by taking him into our confidence, relieving his mind of secret griefs, etc., etc., by suggestion and encouragement, telling him that after all his burden is not so heavy, etc., etc. We can make the hill seem less steep by giving him assistance in the form of food and money, etc., as our philanthropic societies do and are doing, but we are making a mistake if we neglect making the man actually stronger himself, for who knows that in a few years a heavier burden may be put on his back, a steeper hill may lie before him, and our assurances cannot be lasting, and we ourselves may not be on hand to help him. The result of all this is a still more serious nerve relapse.

Has any one ever seen a perfectly organically healthy man or woman, who could long remain unhappy? Has any one ever felt quite the same as when he was in what we call the "pink of condition," as the trained athlete should be before some trial of his strength? Is not the first duty of the physician, after all, the strengthening of the body so it can bear its burdens and nourish the weakened nervous system? I therefore say, while agreeing with eminent authorities on the necessity for better instruction in psychiatry in our medical school, that it is absolutely necessary, and of more value, that a thorough training be given in the application of physical methods. Teach the tailor and the factory girl how to prevent contractions of the chest, the crooking of the back—in fact, everybody, better laws of hygiene; keep your towns and cities clean, free of dust and smoke, lessen the hours of work and increase the hours of recreation, and we will see how happy the dwellers therein will become, and how little need physicians will have for psychic treatment among their patients.

And now, as to the treatment of this mind weary class already among us and probably doomed to be with us, at least in our generation; help them as suggested in all three ways, but by mental methods

only when they really need it. If a man or woman is happy in a hobby, let them retain it or even indulge it for the time being, if it does not harm others. You will often be unable to supply anything better to take its place. Why? For this reason: Nature has ways of protecting her own; when the mind becomes too greatly distressed by effort and worry, it searches around for or oftentimes evolves a theory that is especially fitted to its own satisfaction at the time, and which allows it to rest and find repose. Like certain plants or bacteria, it goes into a resting or spore stage, which the theory allows it to do, when the environment is against its growth, and then the harrassed, worried-looking, and nervous individual acquires a selfsatisfied, benign, and placid expression. In some cases restraint is necessary for the protection of society. For example: The anarchist is a man born with the inability to work, or at least the disinclination to do so. He goes restlessly from one vocation to another until the theory, such a happy one to him, that the rich man should share with him his wealth and luxuries, etc., explains the lack he feels within himself for serious occupation, and he takes up anarchy willingly and happily, works hard, and will even die gladly for the cause. Anarchy, undoubtedly, makes him happier, and if it did not harm the rest of us we could leave him alone with his delusion with possible benefit to himself. The Christian Scientist or the applicant to the mental healer is one born with the disinclination to think; they finally hit on some simple theory which explains everything to their own satisfaction. This lets them out of most of the worries of life, and probably saves a further degeneration of the mind, and may thus help posterity.

The first stage in the degeneracy of the mind, then, is the disinclination to think; a later stage is the inability to think, and at last we arrive at the various stages of imbecility, dementia, etc.

In conclusion, I would say that it seems to me a dangerous procedure to turn even the purely functional neuroses over to untrained men for treatment, even if they can give efficient mental treatment, owing to the impossibility to determine, often, what is organic and what is functional, or how dependent the mental state is on the badly developed or poorly nourished body. I remember very well a case Dr. Osler disagnosticated as organic trouble, which another very eminent physician said was functional. After saying everything bad in the calendar about Dr. Osler the poor patient died a year or so later of organic disease. This is a common experience, and I mention it as showing the impossibility of distinguishing at once or for years in some of these cases. There should always be cooperation throughout the treatment of such cases with a trained physician; at least a month's careful watching and then recurring examinations throughout the treatment, no matter how long it takes to effect the cure.

I think our medical schools should have better courses in psychiatry; but, more important even, as we can always get a specialist in a pinch, and manage fairly well without this special training, would be a thorough knowledge of electrotherapeutics, scientific massage, the administration of heat

and cold, and last, and most important, the problems of nutrition—which we admit are so important in pædiatrics—and often ignore in adult life. That fat reduction, if scientifically carried on, will cure a fat neurasthenic as nothing else will, if you can substitute good muscle for his poor tissues, is an every day experience with those interested in such matters, and a very important problem for the consideration of the general practitioner. I believe, honestly, that gymnastics, outdoor exercise, proper nutrition, etc., will go much further with neurasthenics alone than suggestion will alone. They in themselves are suggestive, and do not weary the mind with argument, and, as I have shown, will make the man stronger to bear the burden of his life, which may become greater when you are no longer at hand to help him. A prize-fighter, asked why he took up the profession, said "he was very nervous as a kid, but when he could lick any man in the room this all left him."

Beware, without much deliberation, using your influence in turning a mind, which sometimes is unfit for your ideas, from the ones which often, as I have said, the wornout mind has evolved for itself, better indeed than you could do for it, and which in a poor state of nutrition of the body may be its haven of rest. Build such a body up, and make the psychic change later. And now, last, but not least, let us, as American citizens, as well as physicians, try and prevent this wave of degeneracy which is spreading over our country, rather than be compelled to cure it after it has fastened itself upon us. Who can read those two articles in *McClure's Magazine*, April and May numbers of this year, without shame? Who can doubt the genuineness, from the evidence given, of the statement that in the midst of one of our greatest cities, in its very centre in fact, there are over 30,000 people who are below the par of the most barbarous savages on the face of the globe? Let us use our influence over our patients to prevent undue emigration, the corruption of politics, and see that our cities are kept clean and hygienic, that proper rules and regulations are carried out in the schools and the factories, etc. Let us, as physicians, teach the people how to prevent disease in their children and themselves, and if they refuse to be taught, let us see that the city authorities compel them to keep just and suitable laws.

It is a great mistake that the building up problem of the human body is ever turned over to ignorant people, and who are less trained in their work and capable of doing more harm than the mental healer could do with his crude psychotherapy. A doctor should be able to give massage and baths, or at least should know whether his employees are able to do so, and the same thing applies to the various physical-culture methods, diet, and a number of other growing necessities. Given a man's age, height, etc., how few of us know his proper dimensions, the strength of his muscles, their capacity, lifting power, etc., or, in other words, what a normal man should be and how to make him so. What nations should twenty men have for twenty days in a certain climate, etc., are practical problems which might and have confronted many a physician most unexpectedly, to his great embarrassment. The

average medical student reads ten books on psychology, or along these interesting and fascinating lines, to one on nutrition or vital statistics, etc., which are unfortunately dry and not very entertaining, but this does not lessen their importance.

This paper is a plea, then, for scientific study along the lines of physical needs and physical development and the scientific teaching of the same—far more important, I consider, than that of psychiatry for men beginning their life work and which we feel the lack of more than anything else when we first start out in the practice of medicine. I trust that this paper may serve as a warning and some help to men with a medical life before them, and may restrain their enthusiasm along a very thorny and hazy path for the beginner—psychotherapy. I remember well in 1898, when I used hypnotism in place of an anæsthetic on some surgical patients in this hospital, with fair success, how enthusiastic I was until I found out what limitations my methods had, and now I earnestly advise you to learn all you can first about building your patients up. Your daily experience will evolve a power for psychic treatment and develop your powers of influence. The younger generation of medicine has a great work before it; its war cry is prevention rather than cure, and especially when considering our neuro-pathic classes.

21 MT. ROYAL AVENUE, WEST.

#### CHORIOEPITHELIOMA MALIGNUM.

By ANTONIO M. CRISPIN, M. D.,  
New York.

The difficulties of diagnosing and the comparative rareness of these uterine tumors, together with their clinical and pathological interest, encouraged me to report the following case, in which I operated in April, 1905, thus adding one more to the scant literature on the subject.

The comparative infrequency of these tumors can best be judged by reading the masterly article by Dr. Robert T. Frank in the *New York Medical Journal* of April 21, 1906, where, in a most exhaustive and comprehensive study, he found but twenty-eight cases reported in the American literature. The nomenclature of these growths has been quite extensive, and various are the terms applied to designate this rare form of neoplasm. It has been designated as deciduoma malignum, malignant bladder mole, sarcoma decidua cellulare, malignant placental polyp, and more recently chorionepithelioma and chorioepithelioma.

The first important study on the subject was published by Sanger in 1889 and was followed by Gottschalk and Frankel. The consensus of opinion as to the origin of this growth accepts the theory advanced by Marchand, that these tumors are of chorionic, fetal, or ovular origin. Voight maintains a contrary opinion, and says that they arise from maternal tissue and not from fetal ones. Frank in the article referred to says: "A chorioepitheliomatous tumor of pregnancy may be defined as a neoplasm which arises from some portion of the fetal covering (ectoderm) invading the tissue of its host, the mother." It was clearly shown by Marchand what

relation the protoplasmic masses of the tumor have with the syncytium and their relation to those of Langerhans's layer. It has also been demonstrated by others that the syncytium and Langerhans's cells are derived from the ectoderm, and therefore these tumors are of fetal or ovular origin, causing a malignant proliferation of the two layers of the chorionic epithelium.

These tumors as a rule follow pregnancy, abortion, or a hydatidiform mole. In my case it was the sequela of an abortion. Metastasis is one of the remarkable characteristics of these growths, and there is a decided tendency to early invasion of other viscera. Malignancy is also a marked characteristic of these tumors. They are usually located in the uterus, but it has been primarily observed in the vaginal and in the fallopian tubes. Generally it follows pregnancy, specially a hydatid mole, but it has nevertheless been observed after the menopause in a woman fifty-eight years old.

The symptoms presented by the patients are usually as follows: After pregnancy, abortion, or the expulsion of a hydatidiform mole, 58 per cent. of cases, there is repeated genital hemorrhages, generally profuse, although it may be scanty. The hemorrhage may be continuous, and in the period of quiescence a thin, watery discharge may appear. Anæmia may supervene. When the disease has advanced the tumor ulcerates, and pieces of necrotic tissue are discharged, the odor of which may become intolerable. Metastases appear in the other organs, ulcerating into bladder or intestines.

The prognosis is extremely grave. The only hope is early surgical intervention. Medication for the control of the bleeding seems not to exert any influence.

The diagnosis is established by the careful consideration of the symptoms and the physical signs. Enlargement of the uterus, resembling a gravid one, varying in size from a five week pregnancy to that of full term. The profuse bleeding, and the removal by curetting of a piece of tissue for microscopical examination, will establish the diagnosis.

The treatment of these cases is that of all malignant growth—extirpation. Curetting aggravates the condition.

CASE.—Mrs. A. S., age forty-nine, has no information to offer about her parents. It may be interesting to know that one of her brothers had been operated upon by me for a sarcomatous growth of the right groin. She always enjoyed good health, menstruated when she was eleven years old, married very young, and has had thirteen living children and two abortions. Her present illness began five months ago, when she aborted at the third month of gestation. Bleeding was very profuse, and as it did not stop she consulted a physician who curetted her, but this only aggravated the condition and the hemorrhage was increased. I was then invited to see her. She was a large, stout woman, very anæmic. On bimanual examination, the cervix felt soft and large, the os quite patulous, uterus globular and about the size of a four month gravid uterus, uniformly enlarged, and freely movable. Hemorrhage continuous. I advised immediate operation, which was accepted, and had her removed to the hospital. I performed a hysterectomy by the combined method on March 7, 1905, assisted by my friends, Dr. Jacob G. Paepke and Dr. Henry Kalvin. Having first curetted the uterus, which was found very soft and bled profusely, requiring immediate packing, I then opened the abdomen, cutting through enormous quantity of adipose tissue, which impeded the delivery of the uterus; this organ was perfectly smooth and large. After some difficulty, due to the thickness of the abdominal parietes and the intense bleeding from the tissues which

tore easily, I succeeded in delivering it. All went well until the fourth day, when the patient developed intestinal paralysis, for which everything was tried, but to no avail, and she died in the evening. The tumor was sent to the pathologist, Dr. N. Kruskal, and he reported it to be a chorioepithelioma malignum, with the usual findings.

854 LEXINGTON AVENUE.

# RHYTHMICAL ALTERATIONS IN THE WIDTH OF THE PALPEBRAL FISSURE OF BOTH EYES PROBABLY PRODUCED BY SPASM OF THE LEVATOR PALPEBRÆ MUSCLES.\*

By C. A. VEASEY, M. D.,  
Philadelphia,

Assistant Professor of Diseases of the Eye, Jefferson Medical College.

At a meeting of this section, held April 15, 1902, Dr. William Campbell Posey reported a case of unusual choreiform alterations in the width of the palpebral fissure of both eyes, occasioned by spasm of the levator palpebræ muscles, which was observed in a colored boy eight years of age, the patient complaining only of slight headache and of a sensation of sand in his eyes, but an examination showed curious rhythmical alterations in the width of the palpebral fissures, the latter widening about fifteen to twenty times in a minute. The contractions were choreic and entirely under the control of the will, the patient being able to initiate them or stop them when told to do so. The excursions of both eyes were normal, there was no nystagmus, and vision and accommodation were also normal. Atropine was employed, the patient refracted, and there was no return of the movements after the patient received glasses.

Posey believed that these curious movements of the eyelids were due to the contraction of the levator muscles of the lids, and that these contractions took place without any assistance of the frontalis muscles, as the eyebrows remained quiescent. There also seemed to be no connection with the act of winking. He thought that the widening was occasioned by the contraction of that part of the levator muscle controlled by the third nerve rather than by contraction of the small portion consisting of unstriped fibres which receives its innervation from the sympathetic. He argued that if the contractions were due to a spasm of the muscle of Müller there would also have been observed changes in the size of the pupils, as the iris is also innervated by the sympathetic.

It was thought that the movements were choreiform in character, the contraction of the levator taking the place of the more common manifestation of habit chorea, namely, the contraction of the orbicularis.

The following notes are of a somewhat similar case:

T. R., aged seven and a half years, both of whose parents were more or less nervous, was first examined April 12, 1907. The child himself had always been nervous and very quick in his movements. For some months there had been observed an upward movement of each upper lid, occurring about twenty times in a minute and sufficiently great in extent to uncover the cornea and expose the sclera above. The movements were much more marked at times than at others, but were especially bad when something

\*Read before the Section in Ophthalmology of the College of Physicians of Philadelphia, November 14, 1902.

occurred to make the child nervous. The movements were rhythmical in character and were in all probability due to contraction of the levator muscles. The frontalis was not involved nor were there any changes in the pupils. Occasionally there were slight contractions of the alae of the nose. Adenoids had been removed some months before, and the patient had also been circumcised.

It was thought that we were dealing with a case somewhat similar to that described by Dr. Posey, and the patient, who had only 6/9 vision in each eye, caused by a simple hyperopic astigmatism, was refracted under atropine and the glasses ordered to be worn constantly. This gave considerable relief, as the contractions of the lids did not occur so frequently, but the movements did not entirely cease until the patient was placed upon ascending doses of Fowler's solution of arsenic.

In this patient the contractions were probably largely due to the condition of the eyes, being a manifestation of habit chorea, but which did not entirely disappear until after the administration of arsenic. It is certainly a somewhat unusual manifestation, and is here reported because of its infrequent occurrence.

1831 CHESTNUT STREET.

## Therapeutical Notes.

**Applications for Acne.**—According to Ohmann-Dumiesnil (*American Journal of Dermatology*), the general treatment of acne is complicated owing to the fact that the affection may be caused by so many conditions. For local application it is generally agreed that sulphur is best. A generally good application is the following:

R Sulphuris præcip., ..... ʒss;  
Ung. aquæ rosæ, ..... ʒi.  
M. Sig.: Apply twice daily.

As a lotion the following formula of Kummerfeld's is stated to be efficient and pleasant to use:

R Sulphuris præcipitatus, ..... ʒiv;  
Pulveris camphoræ, ..... gr. x;  
Pulveris tragacanthæ, ..... ʒi;  
Liquoris calcis, } ..... aa ʒi.  
Aquæ rosæ, ... }  
M. Sig.: Apply two or three times daily.

[This lotion should be ordered to be shaken well before applying.]

In cases in which there are old, hard papules the following will be found useful:

R Hydrargyri oleatis (5 per cent.), ..... ʒss;  
Sulphuris præcipitatus, ..... ʒss;  
Ung. aquæ rosæ, ..... ʒi.  
M. Sig.: Apply thin twice daily.

**The Use of Drugs in Cholelithiasis.**—In the *Therapeutic Gazette* for December, 1907, John H. Musser, of Philadelphia, discusses the medical treatment of diseases of the gallbladder, and with regard to the use of drugs he has to say that there are very few that can be administered with any degree of confidence that results are to be secured, save those indicated from a careful study of the gastrointestinal tract (including the stools and gastric analysis), those that are indicated by a study of the circulation, and those that are indicated by a study of the blood. Among the drugs that have virtue in a general way he places the alkalis first. Where there is congestion or a tendency to stasis ammonium chloride is of value, as it has an in-

fluence upon the secretions and is said to thin the bile, allay catarrh, and modify the amount of mucous secretion. The author thinks that after the establishment of a biliary fistula, the secretion of bile is increased by the use of the salicylates. The value of sodium phosphate and other sodium salts is well known, but whether the result obtained with them is due to their action as cholagogues or as purgatives relieving the stasis, he is not prepared to say. There is no solvent for gallstones that lie quiet in the gallbladder or in the bile ducts, and there is no medicinal means of removing them. Dr. Musser has never seen any relief to gallstones from the use of olive oil; though it sometimes relieves the symptoms in this way: With gallstones there is usually a hyperacidity, which gives either simple gastralgia or pyloric spasm. It is these symptoms that are relieved when olive oil is administered.

**Lotions and Pomades for Alopecia.**—From Schnirer's *Taschenbuch der Therapie* we take the following selection of formulas:

### I.

B Acidi salicylici, ..... 1.0 gramme;  
Tincturæ benzoini, ..... 2.0 grammes;  
Alcoholis, ..... 200.0 grammes.  
M. S. Apply to the scalp once or twice daily.

### II.

R Resorcin, ..... 5.0 grammes;  
Olei ricini, ..... 45.0 grammes;  
Balsami peruviani, ..... 0.5 gramme.  
M.

### III.

B Sodii bicarbonatis, ..... 3 parts;  
Spiritus lavandulæ, { ..... aa 15 parts;  
Glycerini, .....  
Aquæ distillatæ, ..... ad 200 parts.  
M.

### IV.

R Hydrargyri ammoniati, ..... 2.0 grammes;  
Unguenti aquæ rosæ, ..... 50.0 grammes;  
Tincturæ benzoini, ..... 1.0 gramme;  
Olei rosæ, ..... 5 gtt.  
M. S.: Pomade.

### V.

R Quinina, ..... 1.0 gramme;  
Acidi tannici, ..... 2.0 grammes;  
Ung. aquæ rosæ, ..... 100.0 grammes;  
Olei rosulæ (mignonette), { ..... aa 2 gtt.  
Olei neroli, ..... }  
M. S.: Pomade.

[In this formula the oil of mignonette, which is difficult to procure in this country, may be replaced by 1 drop of oil of bergamot.]

**Adherent Cade Ointment.**—At the Hôpital Saint Louis, Danlos, makes use (*Journal de médecine, through The Practitioner*), in different skin affections, especially in psoriasis, of an ointment which has the advantage of being very adherent to the skin and which can only be removed by the use of oil or soap. The formula is:

R Oï cadmi, ..... ʒss;  
Pulv. talci, ..... ʒss;  
Pulv. smectæ, ..... ʒi.  
M. F. unguentum.

The preparation of this ointment entails a lengthy trituration to provide for the complete incorporation of the zinc oxide and the talcum with the oil of cade.

**The Contagiousness of Follicular Tonsilitis.**—The contagiousness of follicular tonsilitis is pointed out by a writer in the *Journal of the American Medical Association*, for January 4, who advises treating it with the same local antiseptics and the same preventive measures against giving the disease to others as are used against diphtheria. It seems to be proved that many attacks of acute inflammatory rheumatism begin by the germ entering the system by way of the tonsils, even if follicular tonsilitis is not present. On the other hand an apparently typical follicular tonsilitis often precedes rheumatic symptoms. If there is much general infection from the tonsilitis, as shown by a high temperature, headache, and backache, one of the following prescriptions should be given:

## I.

R Monobromated camphor, .....gr. iss;  
Citrated caffeine, .....gr. iiss;  
Acetanilid, .....gr. viii.  
M. et fac capsulas 5.  
Sig.: One capsule every three hours, with plenty of water.

## II.

R Acetphenetid, }  
Phenyl salicylate, } .....āā gr. xxv.  
M. et fac chartulas 5.  
Sig.: A powder, with water, every three hours.

The local treatment of follicular tonsilitis and diphtheria is the same, as follows:

R Solution of hydrogen dioxide, .....3vi.  
M. Sig.: Dilute with three parts of warm water and use as a gargle every three hours.

and

R Boric acid, .....3i;  
Water, .....3vi.  
M. et sig.: Use undiluted as a gargle every three hours.

The gargles should be used alternately, each one every three hours (one or the other every hour and a half) during the day time, and every three or four hours at night.

If the patient is debilitated by the inflammation, a simple tonic is needed, which may consist either of strychnine sulphate, gr. 1-30; or a mixture of quinine sulphate, gr. iss and reduced iron, gr. 34, either to be given three times a day.

**Local Applications in Rheumatism.**—For application to painful joints the following combination is recommended in *The Hospital* for November 23, 1907:

R Salicylic acid, }  
Oil of turpentine, } .....āā 3ss;  
Hydrous wool fat, }  
Lard, .....q. s. ad 3iiii.  
M. Sig.: Apply to the parts affected on lint, and cover with gutta-percha tissue and a flannel bandage.

In chronic rheumatism and gout the following may be tried:

R Salicylic acid, .....3v;  
Castor oil, .....3iii;  
M.

Lint soaked in this is applied in the same way as the preceding application.

**Treatment of Comedones.**—Ohmann-Dumesnil, in the *American Journal of Dermatology*, some of the commoner diseases of the skin. In reference to acne punctata or comedo, commonly known as

blackheads, he notes that constipation usually exists, amounting at times to a veritable obstipation. Of course, he remarks, it is necessary to overcome this, the removal of the constipation forming a useful adjuvant to the treatment which may be adopted. In rectal obstipation he says there is no better remedy than a pill of socotrine aloes to be taken every night for several days. The diet should be regulated. The internal remedy preferred by him is arsenic in the form of arsenous acid [arsenic trioxide (U. S. P.)], which he prescribes in the following combination:

R Acidi arsenosi, .....gr. ii;  
Pulv. piperis nigris, .....3ii;  
Ext. gentianæ, q. s.  
M. et ft. cap. No. 60.  
Sig.: One capsule after each meal.

Locally the comedones may be covered with the following paste:

R Acidi acetici dil., .....3iiss;  
Glycerini, .....3ii;  
Kaolini, .....3iiiss.  
M. et ft. pasta.  
Sig.: Apply at night.

**The Medicinal Treatment of Epilepsy.**—During an attack nothing serves so well as the inhalation of amyl nitrite. Between the attacks bromide salts in various combinations are of value. The following prescriptions are adapted from several printed in a recent number of the *Journal of the American Medical Association*:

## I.

R Ammonium bromide, }  
Potassium bromide, } .....āā 3ii;  
Sodium bromide, }  
Syrup of orange peel, .....3i;  
Camphor water, .....q. s. ad 3viii.  
Ft. mistura. Sig.: Two tablespoonfuls three times a day after food.

## II.

R Potassium bromide, .....gr. lxxx;  
Tincture of belladonna, .....℥ xl-lxxx;  
Syrup of orange peel, .....3i;  
Camphor water, .....q. s. ad 3viii.  
Ft. mistura. Sig.: Two tablespoonfuls to be taken three times a day after meals.

## III.

R Ammonium bromide, .....3ii;  
Tincture of digitalis, .....℥ lxiv;  
Syrup of orange peel, .....3i;  
Camphor water, .....q. s. ad 3viii.  
Ft. mistura. Sig.: Two tablespoonfuls three times a day after food.

**Boric Acid Instillation in Otitis Media.**—F. B. Richards (*Lancet*, November 30, 1907, and *Le Bulletin médical*, No. 94, page 1049) recommends, in the treatment of acute and chronic otitis media and other forms of otorrhœa, the instillation of a concentrated solution of boric acid in alcohol and glycerin, as in the following formula:

R Acidi borici, .....4.0 grammes;  
Alcoholis, .....8.0 grammes;  
Glycerini, .....18.0 grammes.  
M.

Twice or thrice daily and, especially mornings and evenings, the ears are syringed out with lukewarm water. The head is then held so the affected ear is uppermost and the drops, previously warmed, are freely poured in.

NEW YORK, SATURDAY, JANUARY 18, 1908

## INDUSTRIAL ACCIDENTS AND DEPENDENCY.

In the highly intricate relationships of the modern social fabric there is one feature that comes prominently forward in the life work of many physicians. This pertains to the alleviation of the suffering of many who are struck down in the struggle of life for shorter or longer periods of time by the numerous accidents of industrial occupations.

In the quarter ending March 31, 1907, according to statistics furnished by the Department of Commerce and Labor, 45,000 accidents were reported in this country, which number represents a totally inadequate idea of the great total. What compensation is afforded these sufferers and their families whereby the necessities of life may be acquired, not to mention that factor which enters into our lives, the payment of the doctors' bills? Prophylaxis and remedial legislation looking toward the diminution of accidents is one phase of the matter which cannot here be discussed. What are the conditions?

The lawyers of large corporations will tell us that the many suits brought for damages are mostly of the nature of blackmail, but the public at large do not believe it if jury awards are to be regarded as expressing the views of the masses; and we, as physicians, also know that this is far from being a proper statement of the case. An investigation of about 400 cases coming to the attention of the New York Charity Organization Society and reported by Francis H. McLean in a recent number of *Charities and the Commons*, December 7, 1907, affords an illu-

minating glance at what really happens in these cases, and as such throws considerable light on the subject, interesting alike to general practitioner, medicolegal expert, lawyer, and judge.

About one half of the accidents occurred to men under forty years of age, that is, in the best part of their industrial life. About 50 per cent. happen to workmen in unskilled trades. This includes laborers, drivers, longshoremen, and others. Taking 241 of the scheduled cases where the wages were accurately determined, they find that forty-six, or 25 per cent., were earning from \$5 to \$10 a week only; and that 144, or about 60 per cent., were earning less than \$15. The tables indicating occupations also show that this range of wages will run about the same in the cases where the weekly returns are not given.

Of the cases scheduled, eighty-two accidents were in the building trades, seventy-six were in connection with factories and machinery, and thirty-seven happened upon the street. This last figure, regarding street accidents, indicates the range of accidents not covered by the reports of the State bureau. It should be stated that, of course, no street accidents were recorded unless they happened to workers whose duty took them upon the streets, that is, drivers and messengers. Those injured on their way to or from business were not included. The schedule of permanently injured reads as follows: Amputations of fingers or toes, seven; amputation of legs, feet, hands, or arms, twenty; brain permanently injured, ten; partially crippled, eight; paralyzed, five; blinded, fifty-three; permanently injured by blood poisoning, two; spine injured, two; internal injuries, three; loss of hearing, one; made deaf and dumb, one; hernia, resulting in partial loss of wage earning ability, at least 250; rendered insane, twenty-one; killed, forty-five.

Coming to the question of donations or settlements by employers, the author limits himself to an analysis of about 200 cases, in which the returns were fairly complete. Of these, some sort of donation or settlement was made in forty-seven, so far as known. Absolute accuracy is not alleged for these figures, but approximation to the total truth. This is about 20 per cent. of the total. This table of forty-seven settlements and donations is a veritable crazy quilt of absurdities when viewed comparatively. For temporary injuries the settlements are generally quite fair. That is, full wages were paid during the period of disability in a number of cases. When more serious results were present, many incongruities were to be observed. As a corollary, the facts regarding litigation, as nearly as they could be obtained, are given. Only the 223 cases which are fairly well scheduled in this regard are taken. The figures given are mu-

tually exclusive—suit begun, nineteen; suit begun, but settlement expected, three; suit begun, with no probable hope of recovery, two; suit begun, but complicated by absolute release, two; suit begun and lost, four; judgment obtained in two cases, one for \$300 and the other for \$200. The \$300 one is appealed, and in the other the lawyer took half for his fee.

With reference to settlements, it should not be forgotten that many elements enter into the individual settlements as they are now made—the question of liability, how much the sufferer was himself to blame, how much the other employees were responsible, and the size of the company and its ability to make generous settlements. These and many personal elements enter in. The net result, however, is one which is disgraceful for a civilized community.

In forty-nine cases where the families were provided with charitable assistance there was a stated expenditure of charitable relief of \$2,646. In many cases, however, such general entries as "rent paid by society" or "church," etc., appear. It is, therefore, a conservative estimate to figure \$50 as an average expenditure in the ninety-two families which were in care of New York charitable societies. In addition, it must be remembered that there were 111 persons who were given hospital care for periods varying from a month to a year; also there must be reckoned the cost to various charitable agencies, public and private, in care of the fifty-three blind. To this must be added the cost of the twenty insane inmates of the State hospitals, also the cost of medical attention in the hernia cases, in many of which the sufferers were provided with free trusses, etc. What the total figures would be involves so much estimating that the committee in this statement of facts does not wish to make the venture. It believes that the amount of money thus expended in relief, through public and private sources, during one year would amount to a good round sum.

But this is not all. In ninety-two cases which were closely under the observation of trained charity agents special pains were taken to have them make returns upon the marked deterioration of the families themselves resulting from the accidents and the conditions which followed. Such deterioration was decided in at least twenty-six of the ninety-two. The forms of deterioration may be thus summarized: Chronic dependency; intemperance, not before present; lowering of standards of living; breaking down in health of widow; family broken up; habit of begging developed; savings used up; furniture pawned; first experience of being dispossessed. When it is remembered that these ninety-two cases include only a small fraction of the cases of permanent disability investigated, the amount of temporary and permanent deterioration becomes a social debt of great

magnitude. What that social debt is, if one were able to-day to know accurately the results of the thousands of accidents which have occurred within the last few years, is the unanswered question.

## SULPHUROUS ACID AND THE SULPHITES AS FOOD PRESERVATIVES.

The chief of the Bureau of Chemistry of the Department of Agriculture, Dr. H. W. Wiley, has recently issued a report of nearly 300 octavo pages giving an account of his experiments with sulphurous acid and the sulphites used for food preservatives as regards their effects upon the human system. In this investigation Dr. Wiley has had the assistance of Mr. W. D. Bigelow, Mr. F. C. Weber, and others. The experiments were performed upon young men who volunteered for the purpose. The sulphurous acid was administered in the form of the gas dissolved in water, and the sulphites were given in capsules. This inquiry is thought to be perhaps of even greater importance than the previous studies of the effects of boron compounds and of salicylic acid and its salts, on account of the more extensive use now made of the sulphurous substances as preservatives of food products.

The unequivocal conclusion is arrived at that sulphurous acid and the sulphites, which have no nutritive value in themselves, exert a distinct deleterious influence when taken in considerable quantities and for more than a very short time. Particular stress is laid upon the great probability of the production of serious lesions of the kidneys, inasmuch as a large proportion of the drugs in question is eliminated in the urine after the formation of sulphuric acid. As a matter of course, these lesions could not be demonstrated, for the young men were not brought to the post mortem table, but there were unquestionable indications of such urinary conditions as could not but result in the long run in actual structural changes in the kidneys, probably of an incurable nature. Dr. Wiley's cautious temperament would naturally compel him to stop short of the infliction of permanent disease, but enough seems to have been ascertained to prove the danger of resorting to sulphurous acid and the sulphites as preservatives of food preparations, and to indicate that even the fumigation of wine casks with sulphur may lead to a dangerous contamination of the wine contained in them, which is said to absorb no slight amount of the sulphurous acid generated.

It really seems as if only the old household preservatives were safe, such as salt, sugar, vinegar, brandy, spices, and smoke, and perhaps some of them should be used less freely than they are at present. Recent national legislation on the subject has come none too soon, and it ought to be supplemented by State enactments.

## THE ÆTIOLOGY OF BERIBERI.

Interest in the ætiology of beriberi continues unabated. In two papers in the *Journal of Hygiene* for October, Axel Holst and he and Theodor Frölich compare ship beriberi, which they consider to be different from true tropical beriberi, to scurvy, and they publish some interesting feeding experiments to show the connection of ship beriberi and scurvy and the relation of diet to the production of the latter disease. The first experiments were performed on pigeons and chickens. In these animals a disease was produced which resembled tropical beriberi more than it did ship beriberi, in that a polyneuritis was frequently produced. It was also shown that many more of the ordinary articles of food were able to produce polyneuritis gallinarum than was formerly thought to be the case; for example, spoiled canned meats.

The mammalian experiments were done on guinea pigs. It was found that a one sided diet of various sorts of grain, groats, and bread produced a disease that corresponded both in its naked eye characteristics and in its microscopic appearances to human scurvy. The disease did not develop, however, when a one sided diet composed of fresh cabbage or fresh potatoes was administered. Dried potatoes, however, did produce a similar disease. This disease was favorably influenced by remedies known as anti-scorbutics. The authors have not been able to produce ship beriberi in guinea pigs in this manner. Those, therefore, who advocate the ætiological relation of mouldy rice and beriberi seem to have the advantage over those who believe in the bacteriological nature of the disease. In some recent experiments made on tropical beriberi in Hongkong, Hunter and Koch (*Journal of Tropical Medicine and Hygiene*, October 15th) have concluded that the organisms found in their culture media which were inoculated with the blood of beriberics were the result of defective technique, and that they have nothing to do with the disease.

## THE BLOOD IN POISONING BY ANILINES.

The number of recorded cases of poisoning by the constant use of coal tar derivatives in this country is quite large, but the effects of aniline and of nitrobenzene and closely allied substances have not been studied to any great extent. A paper on the condition of the blood in workers in factories in which these compounds are produced, therefore, is of some interest. Madden (*Journal of Hygiene*, October) presents a study of the blood in thirteen men who were working as aniline dyers and twenty-one men who were employed in the manufacture of dinitrobenzol. In the aniline workers he

found that there was a slight increase of the erythrocytes, with a decrease in the percentage of the hæmoglobin and in the specific gravity of the blood, a low color index, and evidences of degeneration and imperfect development of the red cells. The differential count of the leucocytes showed a diminution in the polymorphonuclear neutrophiles and an increase in the lymphocytes, the eosinophiles, and the basophiles. In those men who worked in dinitrobenzol the changes in the blood were more marked and the condition appeared after a much shorter time spent in the factory. The number of erythrocytes was greatly reduced, and the hæmoglobin and the specific gravity were correspondingly lowered, giving a normal color index.

The occurrence of basophilic degeneration is one of the earliest phenomena of the poisoning. In cases of chronic poisoning there is a slight leucocytosis, with an increase in the percentage of the lymphocytes. It is difficult to demonstrate the presence of methæmoglobin in the blood by the spectroscope, except in the most severe cases. From a number of animal experiments the conclusion is drawn that both aniline and dinitrobenzol produce methæmoglobin and hæmolysis, and that the condition in workers in these substances corresponds to those in animals artificially poisoned, but is on a smaller scale. The best treatment for poisoning by these substances is by the inhalation of oxygen.

## A "PHOBIA" OF THE HOSPITALS.

Apropos of the recent expulsion from one of the large private hospitals of New York of a patient under treatment for pneumonia, because tubercle bacilli were found in his sputum, it may well be asked if the procedure was really warranted by well founded apprehension of the spread of tuberculous disease to the other patients. It is said to be the policy of similar hospitals to insist on the transfer of such patients, either to one of the free municipal hospitals or to their homes. We do not suppose that the exposure incident to the transfer need have an injurious effect on a patient thus transferred, but the influence of such an arbitrary and apparently harsh course of action on the patient's morale, especially in so severe an illness as pneumonia, must, we should say, be depressing to the degree of distinctly reducing the prospect of his recovery. We can hardly wonder that the hospitals operated by private organizations decline to receive persons manifestly affected with certain infectious diseases, but tuberculous infection, particularly when it seems to be a mere incident in the course of a grave acute disease and discovered after the patient's reception, does not appear to us to matter less so.

## News Items.

**Medical Reciprocity.**—The State Board of Medical Examiners of Texas has established reciprocity with the State boards of Maine, Missouri, Maryland, and Nebraska.

**American Psychological Association.**—Professor George E. Stratton, of Johns Hopkins University, has been elected president, and Professor A. H. Pierce, of Smith College, secretary, of this association.

**Cincinnati Hospital.**—Dr. Louis Schwab has been elected president of the new board of medical directors of this hospital, Dr. C. R. Holmes has been appointed vice president, and Dr. A. B. Isham, secretary.

**The Buffalo Academy of Medicine.**—At the regular meeting of the Section in Medicine, held on January 14th, Dr. Irving M. Snow read a paper entitled *The Curative Value of Rest in Children with Chronic Loss of Appetite*.

**The Gloucester County, N. J., Medical Society** held its annual meeting in Woodbury, N. J., on Thursday, January 16th. The paper of the evening was on *Surgical Diagnosis*, and was read by Dr. Joseph Price, of Philadelphia.

**The Clinical Society of the Elizabeth, N. J., General Hospital** will hold its next regular meeting on Tuesday evening, January 21st, at 9 o'clock. Dr. James S. Green will read a paper entitled *Vis Medicatrix Naturæ* in Surgery.

**Society of Medical Jurisprudence, New York.**—At a meeting held on January 13th, the executive officers of the society were reelected, as follows: Mr. Mortimer C. Adams, president; Mr. John C. West, treasurer, and Mr. Charles Blaney, secretary.

**The Alumnae Association of the New York Medical College and Hospital for Women** held its regular bi-monthly meeting on Wednesday, January 18th. The paper of the evening was read by Dr. Emma D. Wilcox on *Preventive Treatment in Diseases of Women*.

**The Camden County, N. J., Medical Society** held its annual meeting on Tuesday, January 7th, and elected the following officers for the ensuing year: President, E. A. Y. Schellenger; vice president, Dr. W. I. Kelchner; secretary, Dr. J. W. Martindale; treasurer, Dr. W. H. Pratt; librarian, Dr. J. H. Wills.

**Public Lecture at the New York Academy of Medicine.**—Dr. Louis Livingston Seaman will deliver a lecture at the Academy of Medicine on Thursday evening, January 30th, at 8:30 p. m., on the Civil and Military Medical Organizations of the South American States. All who are interested are invited to attend.

**Medical Society of the County of Kings, N. Y.**—The Section in Pediatrics held a meeting on Friday evening, January 17th. Dr. F. A. Marshall presented a case of *Ichthyosis Hystrix*; Dr. J. M. Winfield read a paper entitled *Treatment of Eczema in Infancy and Childhood*, and Dr. L. C. Ager reviewed the French *pædiatric literature* for 1907.

**The New York Diet Kitchen Association** held its thirty-fifth annual meeting on Thursday, January 16th. Addresses were made by the president of the association, Mrs. Villard; Dr. Samuel T. Armstrong, medical superintendent of Bellevue and Allied Hospitals, and Dr. William H. Park, director of the Research Laboratory of the Department of Health.

**The Hartford, Conn., Medical Society** held its annual meeting on January 6th, and elected the following officers for the ensuing year: President, Dr. Frederick S. Crossfield; vice president, Dr. P. H. Ingalls; secretary, Dr. W. H. Van Strander; assistant secretary, Dr. Orin R. Witter; treasurer, Dr. George K. Welch; librarian, Dr. Walter R. Steiner.

**The Military Service Institution of the United States** has made the following awards of prizes for the best essays on current military topics: Seaman Prize, No. 1, \$100, to General A. A. Woodhull, M. D., United States Army; Seaman Prize, No. 2, \$50, to Major C. Lynch, M. D., United States Army; Ames Prize, \$50, to Captain E. A. Helmick, Tenth United States Infantry, and the Fry Prize, \$50, to Lieutenant F. P. Lahm, Signal Corps.

**Illinois State Board of Health.**—At the thirty-first annual meeting, which was held in Springfield on January 7th, Dr. George Webster, of Chicago, was reelected president of the board, and Dr. James A. Egan, of Springfield, was reelected secretary and treasurer. This is the twelfth time Dr. Egan has been elected secretary of this board.

**The Hayden Medal**, offered by the Academy of Natural Sciences of Philadelphia for the most valuable contribution to the science of geology, was awarded to Dr. Charles Doolittle Walcott, secretary of the Smithsonian Institution, on Tuesday, January 7th. Professor Persifer Fraser made the presentation address. The medal is of gold and is awarded triennially.

**The Care of Families in which There Is Tuberculosis** was the subject under consideration at a meeting of the Charity Organization Society of New York, which was held on January 13th, under the auspices of the committee on district work of the society. Brief addresses on the subject were made by Dr. James Alexander Miller, Dr. Silas F. Hallock, and Mr. Edward T. Devine, and a general discussion followed.

**The Society of Regular Physicians of New Britain, Conn.**—At the annual meeting of this society, held on January 7th, the following officers were elected: President, Dr. S. Wellington Irving; vice president, Dr. T. Eben Reeks; secretary and treasurer, Dr. Arvid Anderson. At the close of the meeting the annual banquet was held at the New Britain Club. Dr. Irving, the newly elected president, acted as toastmaster.

**The Ohio State Board of Medical Examination and Registration.**—At a meeting of this board, held on January 9th, the following officers were elected: President, Dr. A. Ravogli, of Cincinnati; vice president, Dr. S. M. Sherman, of Columbus; secretary, Dr. George Matson, of Columbus, and treasurer, Dr. E. J. Wilson, of Columbus. The board announced that twenty-three candidates had passed the examination held in December.

**The Kansas City Academy of Medicine** held its annual banquet on the evening of January 9th. Dr. Frank J. Hall acted as toastmaster, and the speakers were Dr. E. L. Chambliss, Dr. C. Lester Hall, Dr. Thomas C. Holland, of Hot Springs, Ark.; Dr. J. E. Sawtell, president of the Kansas Medical Society; Dr. Charles Babo, president of the Oklahoma Medical Association; Dr. C. C. C. Stephenson, president of the Arkansas Medical Society, and Dr. J. Q. Chambers.

**Bequest to the Iowa State University Hospital.**—By the will of Mrs. Helen J. Gifford, of Davenport, Ia., this hospital will receive \$5,000 which is to be devoted to the maintenance of a free room in the hospital, as a memorial to Mrs. Gifford's son, Waite Lowrey Gifford. The will also provides that about \$20,000 more shall be added to this fund, and if three grandchildren die without issue, a trust of \$75,000, in which they have a life interest, is to go to the hospital.

**The Section in Otology and Rhinology of the College of Physicians of Philadelphia.**—At a meeting held on Wednesday evening, January 15th, the following papers were read: *Further Observations on the Value of Lactic Acid as a Remedy for Certain Conditions of the Nasal Passages*, by Dr. A. W. MacCoy; *Some Applications of the Röntgen Diagnosis to Disease of the Accessory Sinuses*, by Dr. C. L. Leonard, and *Primary Mastoiditis, with Objective Tinnitus Aurium*, by Dr. S. MacCann Smith.

**Ohio Medical Teachers' Association.**—The third annual meeting of this association was held in Columbus, on December 27th, and was the most successful in the history of the organization. The programme included discussions of the details of the entrance requirements and the curriculum of medical colleges and of the standards of medical education in general. About seventy-five members were present and a number of visitors, among whom were the presidents of several literary colleges of the State.

**Section in Ophthalmology of the College of Physicians in Philadelphia.**—A stated meeting was held on Thursday evening, January 16th. Dr. G. Oram Ring exhibited a case showing the result of the removal of a foreign body from the iris. Dr. Howard F. Hansell read a paper entitled *The Subsequent History of a Case of Acquired Cataract in Childhood*. Dr. Walter L. Pyle exhibited a

case of microphthalmos with double inferior total coloboma. Dr. G. E. de Schweinitz read a paper on Obstetric Injuries of the Cornea.

**The Health of Pittsburgh.**—During the week ending December 28, 1907, the following cases of transmissible diseases were reported to the Bureau of Health of Pittsburgh: Chicken pox, 6 cases, 0 deaths; typhoid fever, 70 cases, 8 deaths; scarlet fever, 13 cases, 0 deaths; diphtheria, 11 cases, 3 deaths; measles, 94 cases, 0 deaths; whooping cough, 6 cases, 1 death; pulmonary tuberculosis, 10 cases, 9 deaths. The total deaths for the week numbered 170, in an estimated population of 403,330, corresponding to an annual death rate of 21.91 per 1,000 of population.

**Medical Society of Franklin County, Pa.**—The regular quarterly and annual meeting of this society will be held in Chambersburg, Pa., on January 21st, at 1:30 p. m. There will be an election of officers and of new members. Dr. John W. Croft, of Waynesboro, will deliver the presidential address on Hysteria, and the following papers will be read: Diagnosis and Treatment of Diphtheria, by Dr. Guy F. Asper, of Chambersburg; Uncultivated Acres of the General Practitioner, by Dr. J. Burns Amberson, of Waynesboro, and Gymnastics in Heart Disease, by Robert Oden, M. G., of Hot Springs, Va.

**Medical Association of the Greater City of New York.**—The annual meeting of this association will be held in the Academy of Medicine on Monday, January 20th, at 3:30 p. m. There will be an election of officers for the coming year, and the executive council, the corresponding and statistical secretary, and the treasurer will present their reports, after which the following papers will be read: Newer Methods of Examining the Bladder, by Dr. Frederic Bierhoff; Utereral Catheterization, by Dr. F. Tilden Brown; Lithotomy versus Lithotripsy, by Dr. James Pederesen, and Conservative Prostatectomy, by Dr. Follen Cabot.

**The Mortality of Chicago.**—According to the report of the Department of Health for the week ending January 4, 1908, there were during the week 665 deaths, as compared with 673 for the corresponding week in 1907. The annual death rate was 16.01 in 1,000 of population. The principal causes of death were: Apoplexy, 10; Bright's disease, 44; bronchitis, 20; consumption, 67; cancer, 30; convulsions, 8; diphtheria, 23; heart diseases, 56; influenza, 19; intestinal diseases, acute, 25; measles, 6; nervous diseases, 32; pneumonia, 116; scarlet fever, 14; suicide, 13; typhoid fever, 3; violence, other than suicide, 29; whooping cough, 1; all other causes, 149.

**The East Side Physicians' Association of the City of New York.**—A stated meeting of this association was held on Friday evening, January 17th. Dr. Max Gertler presented a case of congenital heart lesion and Dr. George Dow Scott presented a case for diagnosis. Dr. A. E. Isaacs exhibited a case of carcinoma of the sigmoid causing acute intestinal obstruction, also a wired fracture of the patella, with radiograph. Dr. Abram Brothers presented some interesting gynecological specimens, and Dr. I. Seth Hirsch demonstrated "electric sleep" by means of the Leduc current. Dr. Leon F. Garrigues read a paper on the Causes and Treatment of Backache in Women.

**The Spokane County, Wash., Medical Society** gave a banquet on the evening of January 8th, in honor of the Washington State Board of Medical Examiners, at the close of the semiannual examination of applicants for licenses to practise in the State of Washington. Dr. N. Fred Essig, of Spokane, acted as toastmaster, and addresses were made by the following speakers: Dr. D. Mason, Dr. W. F. Morrison, Dr. Henry S. Martin, Dr. E. B. Nelson, Dr. George K. McDowell, Dr. J. G. Cunningham, Dr. N. M. Baker, Dr. E. D. Olmstead, Dr. M. A. W. Shockey, Dr. T. L. Catterson, Dr. C. M. Doland, Dr. C. W. Sharpless, Dr. W. Johnson, and Dr. W. J. Munley.

**The Bill to Increase the Medical Corps of the Army.**—A bill providing for an increase of the number of colonels in the medical corps of the Army from nine to fourteen; of lieutenant colonels from twelve to twenty; of major-general from sixty to one hundred; and of captains and first lieutenants from two hundred and forty to three hundred, has been favorably reported by the Committee on Military Affairs of the House of Representatives, and of the Senate. The measure provides that contract surgeons may be permanently appointed to the medical corps, and also provides for a reserve medical corps to serve in time of war.

The leaders in both houses seem to look favorably upon the bill, and the probabilities of its becoming a law at this session of Congress seem to be quite strong.

**Scientific Society Meetings in Philadelphia for the Week Ending January 25, 1908.**—Monday, January 20th, Northeast Branch, Philadelphia County Medical Society. Tuesday, January 21st, Dermatological Society; Academy of Natural Sciences; North Branch, Philadelphia County Medical Society. Wednesday, January 22d, Philadelphia County Medical Society. Thursday, January 23d, Pathological Society; Entomological Section, Academy of Natural Sciences; Section Meeting, Franklin Institute. Friday, January 24th, South Branch, Philadelphia County Medical Society; Northern Medical Association. Saturday, January 25th, Samaritan Hospital Medical Society.

**Philadelphia Paediatric Society.**—At a meeting of this society, held on Tuesday, January 14th, Dr. I. H. Jones presented a case of fibroid nasal polypus in a boy, Dr. J. T. Rugh showed a case of spondylitis complicated by a psoas abscess following measles, and a case of Bell's palsy in an infant three months old was shown by Dr. J. Claxton Gittings. Dr. Thomas A. Cope gave a demonstration of the routine methods of differentiating the various fats and casein in infant's stools; Dr. D. J. M. Miller reported a case of empyema and gangrene of the lung complicating typhoid fever, and Dr. John D. Target reported a case of spina bifida with other abnormalities. The annual presidential address was delivered.

**Improvements of the City (Charity) Hospital.**—Plans have been filed for improvements on Blackwell's Island and Randall's Island, as follows: For Blackwell's Island, a four story tuberculosis pavilion, with roof gardens, solarium, and exterior verandas, to cost \$180,000; a one story and attic hospital pavilion for the City Home for the Aged and Infirm, to cost \$75,000; a two story pathological laboratory, to cost \$40,000, and a three story and attic residence for the medical staff, to cost \$80,000. All these buildings are to be grouped around the Manhattan Hospital, of which they are to be annexes. On Randall's Island, a four story home for nurses, to cost \$200,000, is to be added to the plant of the Children's Hospital. The total cost of the five buildings will be \$575,000.

**Philadelphia Branch of the American Pharmaceutical Association.**—The January meeting, which was held on Tuesday evening, January 7th, was devoted to a discussion of the valuation of drugs and assay processes. The following papers were read: Recent Progress in the Chemistry of Alkaloid Estimation, by Professor W. A. Puckner; The Pharmacopoeia from the Viewpoint of a Scientific Worker, by Dr. W. A. Pearson; The Standardization of the Preparations of Digitalis by Physiological Means, by Dr. E. D. Reed; The Standardization of the Preparations of Digitalis by Chemical Means, by Mr. Charles E. Vanderkleck; The Use of the Compound Microscope in the Valuation of Crude and Powdered Drugs, by Professor Henry Kraemer. An interesting discussion followed.

#### Infectious Diseases in New York:

*We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending January 11, 1908:*

Diseases.	January 4-11, 1908.		January 12-19, 1908.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid Fever	37	8	58	6
Smallpox	—	—	2	—
Scarlet Fever	98	—	150	—
Measles	251	30	303	15
Scarlet Fever	148	33	307	49
Whooping cough	—	1	—	—
Diphtheria	138	46	305	42
Polio-myelitis	344	18	41	—
Cerebro-spinal meningitis	51	8	—	—
Totals	1,288	200	2,043	318

**For the Prevention of Tuberculosis in New York.**—On Monday evening, January 27th, a public meeting is to be held in Albany to inaugurate a general campaign of education as to the best methods for the prevention of tuberculosis. The meeting is being arranged by the State Charities Aid Association in cooperation with the State Department of Health. The Hon. Joseph H. Choate will preside and Governor Hughes will be the principal speaker of the evening. Address will also be delivered by Dr. William H. Welch of Johns Hopkins

University; Dr. Eugene H. Porter, State Commissioner of Health; Mr. Homer Folks, secretary of the State Charities Aid Association; Mr. George F. Canfield, vice president of that organization, the Lieutenant Governor and the Speaker of the Assembly.

**The Section in General Medicine of the College of Physicians of Philadelphia** held a meeting on Monday, January 13th, and the evening was devoted to a symposium on the recent advances in knowledge of affections of the heart. The programme was as follows: A case of Adams Stokes disease was presented by Dr. B. F. Stahl, and Dr. George W. Norris exhibited pulse tracing from the same case demonstrating the heart block. Dr. Joseph Erlanger, of Madison, Wis., read a paper on Recent Advances in the Pathological Physiology of the Heart with Special Reference to Arrhythmia. Dr. Lewis A. Conner, of New York, read a paper on the Clinical Study of Heart Cases, and a paper on the Use and Abuse of Digitalis and Other Heart Tonics, was read by Dr. Theodore C. Janeway, of New York. The following formal discussion was held: Dr. John H. Musser, on the Importance of Instruments of Precision in the Study of Heart Cases; Dr. Hobart Amory Hare, on Remedial Measures other than Drugs in the Treatment of Heart Disease; Dr. Alfred Stengel, on Extracirculatory Manifestation of Cardiac Failure, and Dr. Joseph Sailer, on Blood Pressure in Relation to Prognosis in Heart Disease. After the meeting a reception was tendered to Dr. Erlanger, Dr. Conner, and Dr. Janeway at the University Club.

#### Society Meetings for the Coming Week:

**MONDAY, January 20th.**—New York Academy of Medicine (Section in Ophthalmology); Medical Association of the Greater City of New York (annual); Hartford, Conn., Medical Society.

**TUESDAY, January 21st.**—New York Academy of Medicine (Section in Public Health); Medical Society of the County of Kings, N. Y. (annual); Triprofessional Medical Society of New York; Buffalo Academy of Medicine (Section in Pathology); Binghamton, N. Y., Academy of Medicine; Clinical Society of the Elizabeth, N. J., General Hospital; Syracuse, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Medical Society of the County of Westchester, N. Y.

**WEDNESDAY, January 22d.**—New York Academy of Medicine (Section in Laryngology and Rhinology); New York Surgical Society.

**THURSDAY, January 23d.**—New York Academy of Medicine (Section in Obstetrics and Gynecology); Brooklyn Pathological Society; New York Celtic Medical Society; Hospital Graduates' Club, New York (annual).

**FRIDAY, January 24th.**—Academy of Pathological Science, New York; New York Clinical Society; New York Society of German Physicians.

**SATURDAY, January 25th.**—West End Medical Society, New York; New York Medical and Surgical Society; Harvard Medical Society, New York; Lenox Medical and Surgical Society, New York.

**Personal.**—Dr. William H. Welker, assistant in biological chemistry at Columbia University, has been appointed demonstrator of physiological chemistry at the University of Pennsylvania, to succeed Dr. P. B. Hawk.

Dr. Marshall Langdon Price has been appointed secretary of the Maryland State Board of Health.

Dr. Theobald Smith, professor of comparative pathology at Harvard University, has received the degree of doctor of laws from the University of Chicago.

Dr. E. Chapot, provost professor of histology at the University of Rio de Janeiro, died recently.

Dr. James U. Barnhill has retired from the editorship of the *Columbus Medical Journal*, in order to devote more time to his private practice.

Sir Thomas Clifford Allbutt, M. D., regius professor of physics at Cambridge University, was created a Knight Commander of the Bath on December 16th. A complimentary dinner was given him by the Master of Downing College, Cambridge.

Sir William Bennett has been elected president of the Institute of Hygiene, London, to succeed the late Sir W. H. Broadbent.

Dr. Nicholas Senn, whose death occurred on January 2d, had just received the Order of Merit of the Japanese Society of Medicine, in recognition of his services to the Japanese people.

Japan, and had recently been elected an honorary member of the Royal Medical Society of Budapest.

Dr. Clarence J. Broeman, of Cincinnati, has been appointed house surgeon of the New York Skin and Cancer Hospital.

**The New York Academy of Medicine.**—The Section in Ophthalmology will meet on Monday evening, January 20th, at 8.15 o'clock. Dr. J. E. Weeks will present a patient showing iridectomy in glaucoma after the method of Lagrange, and Dr. E. B. Coburn and Dr. Mortimer Warren will present a case of phlyctenular eye disease treated with tuberculin. The paper of the evening will be read by Dr. H. W. Wootton on Final Results of the Extraction of Senile Cataract. There will be an election of officers.

A meeting of the Section in Medicine will be held on Tuesday evening, January 21st, at 8.30 o'clock, when the following papers will be read: The Significance of Acetone Bodies, with a Clinical Method for Their Quantitative Determination, by Dr. T. Stuart Hart; Metabolism in Pneumonia, by Dr. Alexander Lambert and Dr. C. G. L. Wolf; Experimental Notes on Artificial Nutrition, with Special Reference to the Hypodermic Method, by Dr. Herbert S. Carter.

The Section in Laryngology and Rhinology will meet on Wednesday evening, January 22d, at 8.15 o'clock, when the following programme will be presented: Dr. Joseph H. Abraham will present a patient showing a case of neglected syphilis, with marked destruction of the nose, nasal cavities, palate and tongue; Dr. J. A. MacKenty will report three cases of trichinosis involving the upper respiratory passages; Dr. J. E. Newcomb will read a paper entitled *Hæmatoma and Abscess of the Septum*; Dr. Sydney Yankauer will show a specimen of a foreign body removed from the bronchus; Dr. John McCoy will exhibit a new tonsil and faucial pillar separator, and Dr. J. Wolff will present a new method of post nasal tamponade.

The Section in Obstetrics and Gynecology will meet on Thursday evening, January 23d, at 8.30 o'clock. There will be a general discussion of the subject of the management of febrile conditions after abortion and labor, and a paper on Uterine Cysts will be read by Dr. Ulysses Kahn.

**Annual Meeting of the Medical Society of the State of New York.**—The programme for the one hundred and second annual meeting of this society, which takes place at Albany on January 28th, 29th, and 30th, has just been issued. The sessions will be held in the Common Council Chamber, City Hall, corner of Maiden lane and Eagle street, Albany. The time and place of the sittings follow:

**MONDAY, January 27th.**—8 p. m.: Meeting of Council in the anteroom of the Common Council Chamber, City Hall. 8.30 p. m.: Meeting of House of Delegates, Supervisor's Room, City Hall.

**TUESDAY, January 28th.**—Meeting of House of Delegates, Supervisor's Room, City Hall. (Time and place to be selected at the meeting on Monday night.) 11.30 a. m.: Scientific Session, Common Council Chamber, City Hall. 2 p. m.: Scientific Session, Common Council Chamber, City Hall. 8 p. m.: Section in Cutaneous Diseases, Common Council Chamber, City Hall. 8 p. m.: Section in Public Health, Court Room, City Hall.

**WEDNESDAY, January 29th.**—9.30 a. m.: Scientific Session, Common Council Chamber, City Hall. 2 p. m.: Scientific Session, Common Council Chamber, City Hall. 7.30 p. m.: Banquet at Hotel Ten Eyck.

**THURSDAY, January 30th.**—9.30 a. m.: Scientific Session, Common Council Chamber, City Hall. 12 noon: Meeting of Council.

Arrangements have been made with those in charge of the State Tuberculosis Exhibit to have this collection set up in one of the rooms of the City Hall during the meeting, so that those who attend may have the opportunity of studying this subject from a practical standpoint. An important public meeting connected with this work will be held on Monday evening, January 27th, at Harnanus Bleecker Hall. It will be presided over by the Hon. Joseph H. Choate, and addresses will be made by Governor Hughes, Dr. William H. Welch, of Baltimore, and others.

A reduction of a fare and one third from points in New York State, on the certificate plan, has been secured for those attending the meeting.

Dr. Frederic C. Curtis, of Albany, is president of the society, and Dr. Wisner R. Townsend, 125 West Fifty-eighth street, New York, is secretary.

January 9, 1908.

1. Practical Application of Oponic Therapy (*To Be Continued*). By THEODORE C. BEEBE.
2. Mexican Mining Practice from a Tuberculous Point of View. By J. S. KAHN.
3. Chronic Dyspepsia. By JOHN B. DEEVER.
4. A Method of Obtaining Extension for Fractures in the Upper Two Thirds of the Humerus. By HOWARD A. LOTHROP.

2. Mexican Mining Practice From a Tuberculous Point of View.—Kahn remarks that a physician with phthisis could hardly find a better place for practising medicine than a Mexican mountain mining camp. Labor, says Dr. Kahn, is very cheap out there, the average Mexican peon drawing a daily salary of  $1\frac{1}{2}$  pesos or 75 cents in United States currency, the companies usually furnishing them "houses"—one room affairs, occasionally made of *adobe* (bricks made of mud and straw as in our western country), but more frequently jacals of cactus stalks and dried grass. Not infrequently these houses are merely small caves in the hillsides, with a front wall of cactus stalks. In addition to homes, medical care is also furnished them, so that practically every camp of six hundred or more has its own hospital or dispensary with a resident doctor paid by the company. The drug stores are well stocked, the doctor being usually given a free hand in the purchase of drugs and supplies, the companies allowing him more expensive synthetical proprietary preparations, even plenty of diphtheria antitoxine at \$6.50 gold per 4,000 units. An intelligent Mexican is always given as assistant to do the cleaning, the simple bandaging, to help dispense medicines, and to give anesthetics. Tablet medication is used as a rule, as far as possible, but there is always a goodly stock of United States Pharmacopoeia elixirs, tinctures, and fluidextracts to be used when desired. The doctor is supposed, as a rule, to furnish his own instruments (these are admitted to Mexico duty free); and usually no provision is made for beds inside the hospital or for trained assistance. The author remarks that he receives 50 cents gold for an office visit, \$1 for a house visit, double for venereal visits, \$2 for a house visit or each visit to a confinement case, \$5 to \$15 for stab or gunshot wounds, and 50 cents a stitch for superficial wounds. The proportion that he receives is very similar in extent to that of the average doctor north of the Rio Grande. It amounts to enough in a week to about meet living expenses, and does not include the salary. A furnished house is usually given to the doctor, rent free, if married, otherwise the best room in the settlement, that is, a house or room furnished from the point of view of a mining camp, which means, clothes closets, desks, tables, wash-stands, and chairs, and even at times beds, usually all built by the mine carpenter. Still, varnish is not essential to happiness, and canvas seats and backs to chairs, while they do not appeal to aesthetic sensibilities are yet far from uncomfortable. These rooms or houses are frequently lit by electricity, generated in the power house for working the mine hoists, etc. Another not uncommon luxury is a

shower bath with hot water derived from the air compressing machines for ventilating the mines.

4. A Method of Obtaining Extension for Fractures in the Upper Two-thirds of the Humerus.—Lothrop describes his method, which he used in an attempt to correct a marked deformity in a case of fracture of the surgical neck. Under ether union was completely broken up and the following apparatus immediately applied: A tin, internal angular splint was applied, but the short arm of the splint was adjusted to the patient's forearm and the long arm was of sufficient length to reach to a point a little above the level of the acromioclavicular articulation. The vertical arm need not reach above the level of the axilla, provided the coaptation splint reaches the angle of the tin splint for direct resistance. A stiff felt shoulder cap, suitable in size and shape for the patient, was selected. This was padded and placed on the outer aspect of the shoulder. Its front portion covered the vertical arm of the internal angular splint. By means of strapping, the shoulder cap was fastened to this arm of the internal angular splint in such a position that its upper rounded extremity was two inches above the convexity of the shoulder, thus leaving a considerable space. By means of strapping, the tin splint and the shoulder cap were made one piece. By means of one or two rather wide circular strips of adhesive plaster this apparatus was adjusted firmly to the upper arm. Downward pressure on the top of the cap would produce extension in proportion to the degree of force exerted. Pressure directed backward would carry the upper end of the lower fragment in the same direction. A sling was applied for support only of the hand and distal half of the forearm, which was thus maintained horizontal across the chest. A four inch gauze bandage was then applied. The essential features of this apparatus are, first, the careful adjustment of the splints, so as to leave a large free space above the shoulder and under the upper end of the shoulder cap; and, second, the application of the bandage so as to exert pressure on the top of the cap downward and backward. The opposite axilla should be padded and a pad should be adjusted carefully between the front edge of the cap and the arm at the site of fracture, if of the surgical neck, the former to protect from the pressure of the bandage, the latter to help force the upper end of the lower fragment backward.

2. The Importance of Early Recognition and Treatment of Rachitis. By THOMAS S. SOUTHWORTH.
3. False Statements Concerning Causes of Oral Pathology. By S. BLAIR LUNNIE.
4. The Significance of Changes in the Optic Nerve in Certain Affections of the Cerebrospinal System. By WILLIAM CAMPBELL POSEY.
5. Röntgen Ray in Epithelioma. By WILLIAM ALLEN POSEY.
6. Adenomyoma of the Uterus. By THOMAS S. COTTEN.
7. The Oponic Index in Orthopaedic Surgery. By CHARLES O'BRYEN and T. HENRY COTTEN.

4. The Significance of Changes in the Optic Nerve in Certain Affections of the Cerebrospinal System. Posey remarks that the classification of changes in the optic nerve which has been adopt-

ed by most ophthalmologists is based on the location of the inflammation according to its site in the axis of the nerve, the term "papillitis" being used to designate all forms of inflammation which affect the head of the nerve and produce visible ophthalmoscopic changes, while involvement of the nerve in its deeper portion is described by the terms "descending" and "retrobulbar" neuritis. In true papillitis, the swelling of the disc is very great, and while in the early stages the veins less frequently present dilations than in neuritis from meningitis, the retinal vessels become later greatly dilated and tortuous, especially the veins. Hemorrhages and extravasations into the retina are not uncommon. In descending neuritis, the swelling of the papilla is never very pronounced, and there is a disposition for the inflammation to spread to the adjacent retina. The changes in the disc, too, are often most intense at the periphery, the centre being but slightly involved. Hemorrhages and extravasations are not uncommon, and the vessels are not kinked as they pass over the edges of the nerve, as is so often the case in intense degrees of neuritis. Retrobulbar neuritis may be regarded as a mixed condition of interstitial inflammation of the nerve with atrophy. In this variety of neuritis there are at first either no ophthalmoscopic signs or merely those of simple congestion. Later, after the disease has subsided, signs of atrophy usually make their appearance. Retrobulbar neuritis may occur in either an acute or chronic form. In the former, which is induced usually by gout, syphilis, or sinusitis, there is rapid loss of sight with neuralgic pain in the temple. In the latter the loss of sight is very gradual and there is but little pain. Nyctalopia is a frequent symptom in this form of neuritis, the patient declaring that he sees better in a dim illumination, exposure to an excessive light leading to a deterioration in vision which may last for some time. In primary atrophy the disc is gray or grayish white; the scleral ring surrounding the nerve is broadened and the stippling in the lamina cribrosa is plainly visible. In this connection it must be remarked that although this form of atrophy has been described as occurring without signs of previous inflammation, in the early stages of the degeneration the nerve sometimes assumes a dull red tint, due to a superficial overcapillarity, while the deeper portion of the nerve is gray and lacking in circulation. The retinal vessels are but little altered. In secondary atrophy the disc is usually whiter than in the foregoing and the retinal vessels are more or less contracted. In consecutive atrophy the disc is not only pallid, but possesses also a bluish or greenish tint, from the connective tissue overgrowth resulting from the previous inflammation of the nerve. The head of the nerve is considerably shrunken and appears as though filled in by connective tissue, the excavation being veiled. Finally, the retinal vessels are much contracted, and, if, as may be the case, the neuritis originating the atrophy was dependent on an inflammation of the inner coats of the eye, atrophic areas and heaps of pigment may be seen in the retina and chorioid adjacent to the disc.

6. **Adenomyoma of the Uterus.**—Cullen could trace the mucous membrane origin of the glands in

fifty cases of uncomplicated diffuse adenomyomata of the uterus. In six additional cases where squamous cell carcinoma of the cervix complicated adenomyoma of the body the continuity was established in five cases. In two cases of diffuse adenomyoma of the body the clue as to the origin of the glands was destroyed by adenocarcinoma of the body. Thus in only one case out of fifty-six where he expected to find the glands originating from the mucosa, if his view as expressed in 1896 was correct, did he fail to find it substantiated. It will thus be seen that when we include adenomyomata of every kind, whether subperitoneal, submucous, or diffuse, he has been able in fifty-six out of seventy-three cases to trace the origin of the gland element to the uterine mucosa. All adenomyomata of the uterus in which the gland elements are similar to those of the uterine mucosa, and are surrounded by stroma characteristic of that surrounding the normal uterine glands, owe their glandular origin to the uterine mucosa or to Müller's duct, no matter whether they be interstitial, subperitoneal, or intraligamentary, solid or cystic.

7. **The Opsonic Index in Orthopædic Surgery.**—Ogilvy and Coffin observe that tuberculin in small doses at proper intervals is of undoubted value in the treatment of selected cases of tuberculous bone and joint infections. The rise of the opsonic index is accompanied by an improvement in the local and general conditions of the patient, if no secondary infection exists. The opsonic index will prove of value in determining the advisability of discontinuing mechanical treatment, and in determining the prognosis in tuberculous bone and joint disease. While there are discharging sinuses and mixed infections the opsonic index may be raised by the use of tuberculin, without an accompanying improvement of the general or local conditions.

#### MEDICAL RECORD

January 11, 1908.

1. The Plague, By ALVAH H. DOTY.
2. The Renal Complications and Sequelæ of Influenza, By HEINRICH STERN.
3. Influenza of the Nose, Throat, and Larynx, By W. SOHIER BRYANT.
4. Duchenne of Boulogne. A Biography and an Appreciation, By JOSEPH COLLINS.
5. Relation of Accidents to Functional Nervous Diseases and Psychoses; Medicolegal Considerations, By ALFRED GORDON.
6. Foetid Breath ("Bromopnea"), By WILLIAM J. LEDERER.
7. Forms of Tubercle Bacilli Which Cannot Be Colored by Ziehl-Neelsen Stain, By C. A. TREUHOLTZ.

3. **Influenza of the Nose, Throat, and Larynx.**—Bryant remarks that the treatment of influenza of the nose, throat, and larynx is abortive, local and general, besides the treatment of the complications. The abortive treatment consists in the local use of astringent antiseptics which sometimes abort and often ameliorate the virulence of the infection if they are applied immediately on the appearance of the first sign of local discomfort, pain, or oedema. Silver nitrate in 10 per cent. solution, painted on the affected area has given much satisfaction. Alcohol 99 per cent. with equal parts of glycerin has worked nearly as well. Local treatment is directed to the relief of the oedema, assuaging pain and tenderness, and cleansing and partially sterilizing the mucous

surfaces. In the nose and throat this may be accomplished with silver nitrate; a solution in strength of from 2 to 5 per cent, applied with a swab has given good results. Argyrol, up to 30 per cent., on a swab is good. When there is a false membrane, a spray of hydrogen peroxide is indicated. After the acute stage is passed and the œdema gone, a spray of Dobell's solution seems to facilitate expectoration of the mucopurulent secretion. When the discharge has lessened, an alkaline aromatic spray is desirable to finish up with. Hydrogen peroxide gargle is indicated for the throat if a purulent condition exists there. In the larynx, the applications must be considerably reduced in strength. Silver nitrate in 2 per cent. solution can be applied with a swab or spray after cocaineization. Alcohol 95 per cent., and glycerin, each one ounce, ferric chloride, 15 grains, and water, two ounces, make a good spray. The general treatment demands absolute rest in bed and light purgation followed by stimulation, especially circulatory, to keep up the failing strength. Special attention must be paid to keeping up nutrition. The ingestion of large quantities of physiological salt solution is desirable to help the naturally increased diaphoresis and stimulate diuresis for the purpose of washing out the toxins. Small doses of salol (gr. iii), calomel (gr.  $\frac{1}{8}$ ), and sodium bicarbonate (gr. x.) tend to keep the alimentary canal in good order. General anodynes and hypnotics are to be chosen with care to avoid the weakening of the heart's action. Dover's powder or codein seems to be satisfactory. Trional can be used with care. The pains may be greatly relieved by the application of heat or counter-irritation. The nasal occlusion is best managed with a 2 per cent. cocaine spray followed by adrenal powder and an alkaline aromatic spray. The sinus complications are treated by keeping the nose free by the method already described. If that is not sufficient, the hot nasal douche should be used; take two quarts of salt solution as hot as can be borne with half an ounce of sodium bicarbonate, and use a fountain syringe at an elevation of six inches, allowing the solution to run into one nostril and out the other. After the douche use some aromatic spray. The tonsillar condition can be treated by strong applications of silver nitrate up to 15 per cent., or by hydrogen peroxide gargle or spray preceded by a hot water gargling. If there is an accumulation of pus an incision is indicated to evacuate it.

**5. Relation of Accidents to Functional Nervous Diseases and Psychoses; Medicolegal Considerations.**—Gordon speaks of his extensive experience among all accidents and cites cases as examples for points he wishes to bring out. In conclusion he remarks that in cases of railway or other injuries caused by neglect of those who have in charge the management of transportation cars, it is no more than just that the injured person should be compensated for disability. On the other hand simulation or exaggeration of incapacity should be condemned. The physician is indispensable to the law. In the name of justice he must be invariably reserved in his statements. His opinion must be formed after a thorough study of each individual case. He must not forget that, while some severe traumatism produce mild symptoms, some insignifi-

cant traumata cause marked disturbances of the nervous system. The degree of the disability and the prognosis of the affection vary in each individual case. The recognition of the affection, the recognition of the influence of the accident upon its manifestations, finally the discrimination of a genuine malady from a simulated one—all these elements can be acquired only when the physician is properly prepared. In view of the practical importance of the subject, a continuous study of it is indicated.

**7. Forms of Tubercle Bacilli Which Cannot be Colored by Ziehl-Neelsen Stain.**—Treuholz's investigations seem to show that the tuberculous virus frequently exists in some form that cannot be stained by our usual methods and which is capable of rapidly developing into the fully grown tubercle bacillus capable of being stained by the method of Ziehl-Neelsen. It is hardly possible that the large number of bacilli found after incubating the spleen can be accounted for by rapid division of those that may be present in the tissue, and moreover single bacilli were the rule in the incubated tissue; it was further found that the spleen which had been incubating three weeks did not show any marked increase in the number over that of four days. In drawing conclusions from the granules found, says the author, we are confronted with several sources of error, namely, the possibility of the presence of other Gram staining organisms, precipitated stain, and points of deeply staining chromatin; these errors were excluded as much as possible by cultural experiments and staining of control slides of normal tissue. An interesting point noticed in these investigations was that the Gram staining bacilli showed a much greater frequency of beading than the Ziehl-Neelsen stained bacilli. These investigations open up an interesting field of work and will probably prove of utility in the study of negative sputa and other tuberculous products where the tubercle bacillus has hitherto been very difficult to find.

1. The Mental Origin of Neurasthenia and Its Bearing on Treatment, By D. DRUMMOND.
2. Clinical Remarks on Tuberculous Chlorosis, By A. JAMES.
3. The Automatic Rhythm of the Heart, By A. M. GOSSAGE.
4. Locomotor Ataxia: Its Early Recognition and General Management, By E. A. DENT.
5. An Open Method of Ether Administration, By F. W. BAILEY.
6. An Open Continuous Drop Method of Administering Ether, By A. BROWNLEE and J. L. THOMAS.
7. Malignant Endocarditis Lasting Over Six Months Without Bruit, By R. CAPES.

**1. Neurasthenia.**—Drummond states that in neurasthenia the physical symptoms are without pathological basis. With rare exceptions an established nervous temperament has been inherited. Overwork, mental strain in business, the grief of bereavement, or some alarming shock do not in themselves produce neurasthenia and cannot be said to be its cause, though by lowering health and weakening mental control they may contribute to the development of the more serious disturbance. But uncontrolled and bad habits of thought in early life have a cramping and con-

aging effect on the mind. Among the points indicating the neurotic nature of the symptoms are the following: Neurotic pains are often described as constant, as always present during waking hours; organic pains are seldom so described. The language employed in describing symptoms is generally exaggerated, expansive, and florid. Neurasthenic patients usually bring with them some relative or friend to endorse their story, though they may be perfectly well able to describe all their symptoms in detail. *Pari passu* with the progress of the symptoms there is evidence of an ever increasing nervousness. This is valuable, because in cases of organic disease the functional aspect becomes less noticeable as the disease advances. As regards treatment the point of chief importance is mental treatment administered under the most favorable conditions, of which the first essential is isolation under the doctor's control. The mental treatment is, in fact, a sort of education with encouragement. The plan adopted should not be too rigid, treatment being always directed, in one way or another, to the one end of leading the patient away from the constricted, self-centered habit of mind in which attention is absorbed in narrow personal feelings, and substituting an interest in the wider affairs of life. To this main object the various helps of rest, over feeding, massage, etc., can be regarded only as subordinate accessories.

2. **Tuberculous Chlorosis.**—James states that in cases which present in a more or less marked degree all the ordinary appearances of chlorosis, and yet in which the examination of the blood shows the red corpuscles and hæmoglobin to be normal, there is very often found a history of past or present tuberculous disease. This is the condition called by Trousseau false chlorosis or tuberculous anæmia. Anæmia in tuberculosis is now well recognized, but the possible association of tuberculous disease in cases of apparent chlorosis is often overlooked. The writer suggests that in these cases there is really an oligæmia—that is, a diminution in the total amount of blood. This theory explains why on recovery we get associated with increased volume of blood improvement alike in the appearance and in the nutrition and vigor of the patient, and yet the hæmocyto-meter and the hæmoglobinometer show little or no change. In the treatment of tuberculous anæmia the use of iron is, as a rule, to be avoided, its place being taken by arsenic and general therapeutic measures, such as hydrotherapy, salt water baths, etc.

3. **The Heart Rhythm.**—Gossage states that there are two opposing theories as to the origin of the automatic power of the heart to beat rhythmically, both of which recognize that the automatic power of the heart lies in itself, and is quite apart from the central nervous system or the circulation of the blood. These are the so called neurogenic and myogenic theories, implying that the origin of the impulse lies in the nervous and muscular elements respectively. The writer thinks that the complete myogenic theory has the more weighty evidence in its favor and should be accepted until stronger arguments are brought against it. It is not incompatible with any of the known phenomena of the heart beat, while it affords the best explana-

tion of many of them. It is certain that the muscle fibres possess the powers of contractility, excitability, conductivity, and tonicity, and it is probable that these are exercised during the normal beat of the heart without the intervention of the nervous tissue. It is also certain that all the muscle fibres are not capable of building up a stimulus for themselves, but there is evidence to show that certain fibres of peculiar structure possess this property. While certain facts seem to find their readiest explanation in the neurogenic theory, especially the response of the quiescent heart to the stimulation of the accelerator nerve, there are others pointing as strongly to the hypothesis that the heart beat is purely muscular. This conception does not preclude the possibility of the beat being influenced by outside nervous impulses. This would give a sufficient explanation of the large nerve supply of the heart. Attributing the rhythmic power of contraction to the muscle is, of course, only a very partial explanation of the cardiac beat, the cause of which lies deeper in physico-chemical changes in the cells.

4. **Locomotor Ataxia.**—Dent holds that locomotor ataxia is essentially a chronic and progressive disease, and that from a strictly curative point of view little can be expected. The course is usually very long—twenty or thirty years. Our aim, therefore, should be chiefly to relieve the symptoms and to arrest or retard the degenerative process as far as possible. Syphilis is responsible for most of the cases. Fatigue, excesses, cold, trauma, overstrain, intoxication, etc., are considered to be exciting causes. If syphilis be treated early and thoroughly, the probability of tabes is only lessened, not removed. The earlier the diagnosis, the better the outlook. Cases showing dyspepsia, neuralgia, burning sensations and numbness in the hands or feet, eye and laryngeal symptoms should always be carefully investigated. A valuable aid in early diagnosis is examination of the cerebrospinal fluid; if there is not excess of lymphocytes present, locomotor ataxia (and also general paralysis) can confidently be excluded. The cases may never advance beyond the preliminary or pretoxic stage. Retention and incontinence of urine with cystitis, etc., are common symptoms. Salol and urotropine here give excellent results, and it may also be necessary to wash out the bladder. Dyspnoea or laryngeal crises are, as a rule, not serious and may be relieved by a few whiffs of amyl nitrite or chloroform. Perforating ulcers may form on the foot, and are to be treated by prolonged rest in bed and antiseptics. Fractures of the bones are caused easily, and unite quickly with a great amount of callus, the condition being akin to the arthropathic changes seen in the joints where there is rapid effusion and abnormal movement (Charcot's joints), the knee being the joint most commonly affected. Frenkel's exercises are the best form of treatment for the ataxia, and even the worst cases show improvement. They should be carried out under the eye of the doctor and be persevered with for not less than a month. In certain cases the x rays applied daily for five minutes to the dorsal region of the spinal column give good results. Baths in general aid the circulation and are refreshing and comforting. Benefit has been noted from the suspension treat-

ment, but it is probably due to suggestion. Both galvanic and faradic currents have been used, but without any great result. Cold and damp climates aggravate the pains. Potassium iodide and mercury are largely given, but have little influence. Silver nitrate in one quarter grain doses often relieves and lessens the pains and does permanent good. Aluminium chloride, gold chloride, zinc phosphate, and arsenic certainly help in some cases. Strychnine is constantly employed for its tonic effect. Penacetine and antipyrine are used for the relief of the pains and morphine should be postponed as long as possible. Testicular juice, spinal cord, brain substance, and spermin have been tried, but with very unsatisfactory results. Tabetic patients should not marry.

## LANCET.

December 28, 1907.

1. The Personal Factor in Diet, By C. J. MACALISTER.
2. Constitutional Development and Social Progress of Boys and Girls from Infancy, By F. WARNER.
3. A Series of Four Cases of Infantile Gangrene of the Cornea in which the Treponema Pallidum Was Found, By S. STEPHENSON.
4. Revealed Tuberculosis in Children at School Ages, from Four to Fifteen Years, By H. C. LECKY and W. C. HORTON.
5. Observations on Cases of Streptococcal Meningitis, By W. J. WILSON.
6. A Case of Diarrhoea, Erythema, and Asthma Apparently Due to Nasal Disease, By J. W. STENHOUSE.
7. A Note on the Treatment of Pyorrhoea Alveolaris by Inoculation with a Bacterial Vaccine, By D. W. CARMOLT-JONES and J. E. HUMPHREYS.
8. Appendicectomy in Chronic Dysentery, By J. A. POTTINGER.
9. Nontuberculous Intranasal and Postnasal Abnormalities: Their Recorded Association with Tuberculosis, By W. C. RIVERS.

3. **Infantile Corneal Gangrene.**—Stephenson reports the details of a series of four cases of keratomalacia in all of which the treponema pallidum (*spirochaeta pallida* of syphilis) was found in scrapings from the necrotic cornea. Keratomalacia is a grave affection of the cornea, apt to supervene in infants whose vital resistance has been reduced by general illness, such as congenital syphilis, tuberculosis, or ileocolitis. It has a distinct seasonal incidence, the majority of cases resulting from ileocolitis. The cases are characterised first by atropia, and secondly by a sloughing condition of one or both cornea, associated with but slight symptoms of local reaction, such as redness, reflex blepharospasm, or swelling of the eyelids. Curious, dry, frothy looking patches of xerosis may sometimes be found in the ocular conjunctivae, but are not essential to the diagnosis. The necrosis of the cornea is not due to any particular microorganism; any pyogenic microbe may cause it, e.g. the various staphylococci, the pneumococcus, the colon bacillus, and the xerosis bacillus. Keratomalacia often leads to destruction of the cornea, and to the death of the patient, usually from bronchopneumonia.

4. **Revealed Tuberculosis in Children.**—Lecky and Horton have examined a number of school children for the purpose of determining the amount of revealed tuberculosis among them. Their conclusions are as follows: 1. The amount of revealed (or recognizable) tuberculosis in school children is very small. They found but three cases in 806

children. 2. The extremely small percentage of cases of pulmonary tuberculosis found among unselected school children, as contrasted with the relatively large percentage of cases of pulmonary tuberculosis found among school children specially referred to a doctor owing to a suspicion of, or evident ill health, indicate that when pulmonary tuberculosis does start in children they quickly show it by failing health and are removed from school. The schools cannot, therefore, be considered as places where much tuberculosis is spread.

9. **Nasal Abnormalities and Tuberculosis.**—Rivers has renewed the literature on nontuberculous intranasal and postnasal abnormalities, and their association with tuberculosis. The commonest abnormalities are those simple ones leading to nasal obstruction (such as septal deformity, turgescence, and hyperplasia of the nasal mucous membrane) and also atrophic conditions. All writers agree that abnormal intranasal conditions are more common in consumptives than in the nontuberculous. The oval cavity, or an abnormal nasal mucosa, cannot be expected to perform the complex physiological functions requisite to prepare the air for the lungs. Not one writer doubts but that the intranasal precedes the pulmonary condition. The evidence seems complete that impairment of nasal respiration, more probably, perhaps, than any one of its many sequelae, is a definite predisposing cause of pulmonary tuberculosis. Most authors pronounce for direct pulmonary infection from inhalation of unfiltered air. So that rhinology should play an important part in the prophylaxis and treatment of consumption. The simple catarrhal laryngitis common in consumptives is dependent on intranasal conditions and not solely due to the exertion of coughing. Rhinological treatment in such cases may be the means of averting tuberculous laryngeal disease. As to prophylaxis the application to the physically selected classes and to school children is obvious.

## LA PRESSE MEDICALE.

December 18, 1907.

Opening Lecture. By Professor PRENANT.

December 21, 1907.

1. Synergic Action of the Gastric and Pancreatic Juices upon Fæcula, By H. ROGER and H. C. SIMON.
2. The Functional Action of the Aperture of the Stomach in Animals with a Permeable Pylorus on Which Gastroenterostomy Has Been Performed, By M. GUIBE.
3. Osteomalacia, the Suprarenal Capsules and Adrenalin, By R. ROMME.

1. **Synergic Action of the Gastric and Pancreatic Juices Upon Fæcula.**—Roger and Simon assert that the various secretions met with in different parts of the digestive canal reinforce each other. Thus the saliva, checked by the acidity of the gastric juice, the pepsin, checked by the alkalinity of the duodenal secretions, are not deprived of their entire influence, but aid in the amolytic action of the pancreatic juice. If they have lost their zymotic power they have kept their zymosthenic power.

2. **Functional Action of the Aperture of the Stomach in Animals with a Permeable Pylorus on Which Gastroenterostomy Has Been Performed.** Guibe presents the following conclusions:

sions: 1. In every case of gastroenterostomy performed upon stomachs in which the pylorus is more or less permeable a spontaneous obliteration of the artificial opening should be expected. 2. If, after a cure of some duration, the former morbid symptoms should reappear, medical treatment should be adopted. If this should fail there should be no hesitation in having recourse to another surgical intervention, which may perhaps demonstrate the closure of the previous anastomosis. 3. In every case, to guard against this inconvenience as much as possible, the anastomotic opening should be placed as near as possible to the pylorus and should be made as large as possible. The method of suturing is also, without doubt, of great importance.

December 25, 1907.

1. Opening Lecture. By PROFESSOR NICOLAS.
2. Bismuth Subnitrate in Diseases of the Stomach, By FERNAND LEVY

**2. Bismuth Subnitrate in Diseases of the Stomach.**—Levy alleges that the favorable effects produced by bismuth subnitrate in certain diseases of the stomach are not wholly due to its physical action in coating the surface of the mucous membrane, but that they are partially due to a chemical action produced in which it is partially precipitated in the form of the oxychloride. It lessens the phase of gastric digestion by reducing the hyperchlorhydria and it tends to suppress fermentation.

LA SEMAINE MEDICALE.

December 18, 1907.

- A Case of Adams-Stokes Syndrome without Blocking, By PROFESSOR R. LEPINE.

**Adams-Stokes Syndrome Without Blocking.**—Lepine's patient was a woman, sixty-five years of age, rheumatic, nervous, overworked, who had suffered for nine years from epileptiform attacks, or, rather, fainting fits. Her heart was enlarged and there was a slight mitral stenosis, and her pulse was very slow. This association of slow pulse with epileptiform or fainting fits forms, in the author's opinion, the syndrome of Adams-Stokes disease, although some authors have used the term "heart block" as synonymous.

December 25, 1907.

- Occlusion Form of Sigmoidispermoiditis, By F. LEJARS.

**Occlusion Form of Sigmoidispermoiditis.**—Lejars reports a case in which the symptoms of ileus were produced in a woman, sixty-eight years of age, by an inflammation of the sigmoid, which caused perforation and aperispermoiditis. Operation failed to save the patient, who sank and died twenty-four hours later without pain, vomiting, or the slightest reaction.

BERLINER KLINISCHE WOCHENSCHRIFT

December 16, 1907.

1. Concerning the Development and Present Stand of the Serodiagnosis of Syphilis, By A. WASSERMANN.
2. Experimental Contributions to the Morphology and Biology of Malignant Tumors, By C. LEWIN.
3. Concerning the Fibrolysin Treatment of Perigastric Adhesions, By C. MICHAEL.
4. Permanent Cure of Perspiration of the Hands by the Use of Exophthalmic Goitre and the Sexual Life of the Woman, By N. KRON.
5. Congenital Stenoses of the Urethra, By A. HOCK.
6. Observations on the Human Semen by the Dark Field Illumination, By C. POSNER.
7. Fibrolysin Treatment of Perigastric Adhe-

sions.—Michael reports two cases in which cicatricial adhesions about the stomach which were the results of operations which had been performed were dissolved by injections of fibrolysin and thiosinamin, made subcutaneously in the neighborhood of the cicatrix.

**4. Permanent Cure of Perspiration of the Hands.**—Kronmayer reports three cases in which hyperidrosis of the hands was cured in two and reduced to a slight degree of perspiration in heat in the other by exposure of the hands to the action of the x rays. He believes that the x rays may be considered, in the true sense of the word, a radical means of cure of hyperidrosis.

**5. Exophthalmic Goitre and the Sexual Life of the Woman.**—Kron reports two cases of women afflicted with exophthalmic goitre the symptoms of which were worse during pregnancy and improved after confinement. In one the goitre became reduced from 37 to 34 cm. The effect on menstruation is discussed, and the author considers that we have to deal with in exophthalmic goitre a disturbance of the metabolic processes of the first importance, as in diabetes. Menstrual disturbances are produced by the chemically changed blood just as in general disturbances of nutrition, and many authors are justified in considering these symptoms as indicative of exophthalmic goitre.

**6. Congenital Stenoses of the Urethra.**—Hock reports two cases of congenital stricture of the urethra. The first patient, a man, seventeen years of age, came under observation on account of a retention of urine. The principal evidence that the stricture was congenital came from the statement of the patient's mother that from his earliest infancy he had had trouble in urination. He also had nocturnal and diurnal incontinence and hæmaturia. External urethrotomy proved to be necessary to give relief. The second patient was a man, forty-seven years of age, who had likewise had difficulty in urination from early infancy. In this case, in addition to a stenosed orifice, there were two strictures, one four centimetres from the orifice, the other in the pars bulbosa. The author also refers with less detail to two additional cases of this rare affection which have come under his observation.

MÜNCHENER MEDIZINISCHE WOCHENSCHRIFT

December 10, 1907.

1. The Analysis of the Extrasystole in the Picture of the Auricular Pulsion, By RAUBENBERG.
2. Cylindruria and Albuminuria, By ASCH.
3. Investigations Concerning Mendel-Bechterew's Reflex of the Dorsum of the Foot, By OSANN.
4. Decapsulation of the Kidney in Eclampsia, By FRANK.
5. Concerning the Postoperative Pulmonary Complications and Thromboses after Etherizations, By OTTE.
6. Concerning the Worthlessness of the Addition of Preparations of the Suprarenal Capsules in Lumbar Anæsthesia, By MICHELSSON.
7. Epididymitis Erotica, By WÄLSCH.
8. A Case of Total Extirpation of a Cyst of the Pancreas, By SCHMIDT.
9. A Case of Swine Erysipelas in Man and its Cure by Means of Swine Erysipelas Serum, By WELZEL.
10. Pigmentation of the Nails in Secondary Syphilis, By VORNER.
11. Sterile Raw Catgut, By KUHN.
12. Fibres of the Utricle Nivea as Surgical Threads, By MADENER.
13. A Simple Fermentation Saccharometer, By BÄSLER.
14. Birth and Death Among the Wandering, By KRAUSS.
3. Mendel-Bechterew's Reflex of the Dorsum

**of the Foot.**—Osann thus sums up the results of his investigations: 1. The normal extension reflex of Mendel arises through direct stimulation of the extensor brevis digitorum. It is almost constant in health. Its occurrence may be prevented by external hindrances, such as œdema, changes in the joints, voluntary tension of the extensor, and atrophy of the muscles. 2. The absence of the extension reflex alone is of no special diagnostic importance, but attains a certain value when it cannot be explained by the mentioned external hindrances and is associated with pathological flexor reflexes. The absence or presence of the extension reflex serves to a certain degree as a measure of the Mendel-Bechterew reflex, and in consequence there can be distinguished a positive and a partial Mendel-Bechterew. 3. The Mendel-Bechterew reflex appears in cases of organic spastic paresis of the lower extremities. It occurs in many cases in which Babinski's reflex is present, but is not so comprehensive. In rare cases there may be a positive Mendel-Bechterew with a negative or uncertain Babinski. 4. Although these two reflexes are so frequently associated they have nothing in common. Babinski's is a purely cutaneous reflex independent of the muscular tone of the lower extremities, while the existence of the Mendel-Bechterew seems to depend on a hypertonic condition of the flexor muscles of the foot and toes. Very frequently it is associated with foot clonus. 5. A distinct analogy exists between the Mendel-Bechterew reflex and the flexor reflex of the finger described by Bechterew.

4. **Decapsulation of the Kidney in Eclampsia.**—Franck reports a case in which decapsulation of the kidney was performed with excellent result in a desperate case of eclampsia.

5. **Postoperative Complications After Etherization.**—Otte thinks that he has succeeded in avoiding the postoperative pulmonary complications which occasionally follow the administration of ether by such a manner of administration as shall avoid an overdose of the drug and by prophylactic measures, such as clearing up of acute troubles of the respiratory organs if possible before operation, having the patient's stomach empty at the time of operation, avoidance of sudden chills during and after the operation and washing out of the mouth with a disinfectant lotion before the operation. In particular he emphasizes the inhalation of steam for half an hour before and after the operation.

7. **Epididymitis Erotica.**—Wälsch deals under this name with a distention of the epididymis dependent on congestion produced by psychical or mechanical excitation of the sexual organs but in no way inflammatory.

10. **Pigmentation of the Nails in Secondary Syphilis.**—Vornier reports a curious case, in which a man, twenty-one years of age, contracted syphilis and simultaneously with the appearance of the secondary eruption black places appeared in the lunula of the finger nails which grew larger from week to week. The pigmentation of the nails was not uniform. On the left hand the fifth finger alone was strongly marked, and the pigmentation was not perfectly even.

# THE GLASGOW MEDICAL JOURNAL.

December, 1907.

1. Breisky's Kraurosis Valvæ; Four Cases, Three of Them Complicated with Epithelioma.

By JOHN EDGAR.

2. The Physiopsychology of Hallucination.

By J. H. MACDONALD.

2. **Hallucination.**—MacDonald speaks of hallucinations. He remarks that the student of history cannot help being struck by the part played by hallucinations in the story of human progress. In the annals of every nation, even from the remotest periods, we meet with hallucinatory episodes affecting the trend of popular thought and belief, and directing the conduct of the people. In some instances we find that the hallucinations pertain to a particular individual, who interprets the hallucination as a mysterious, divine revelation, an interpretation which, begetting in its turn the secret belief in a divine mission, dominates the consciousness, leads to concentration of thought, a determination of purpose, and an accumulation of energy that urges on the hallucinated being to a realization of his dream, and sometimes makes him a leader of men. Thus, we find Joan of Arc in the history of France. But history also furnishes instances of hallucinations affecting masses of humanity. As example the author cites the hallucinatory epidemics that affected whole communities and armies during the holy wars, and here also one individual, Peter the Hermit of Amiens. Biographers relate hallucinatory episodes in the lives of many illustrious men of all times, some of them men of undoubted genius. Martin Luther, according to the evidence of his own writings, was undoubtedly subject to auditory hallucinations. So also was George Fox, the founder of the Society of Friends. Socrates, the ancient Grecian philosopher, is judged to have been the victim of hallucinations. Descartes, after long confinement, was followed by an invisible person calling upon him to pursue the search of truth. It is recorded by Lombroso that Van Helmont declared he saw a guardian angel appear to him in all the most important events in his life. Napoleon was said to have had interviews with a familiar spirit in the form of a little red man, and he asserted he saw his star in every great occurrence. Oliver Cromwell, while lying tired and sleepless in bed, had an apparition of the gigantic figure of a lady who told him he would be the greatest man in England. Johnson when at Oxford one day heard his mother distinctly call "Sam," though she was then at Lichfield. Cowper was one day found by his medical attendant with a penknife sticking in his side. He believed he had heard a voice from heaven commanding him to take his own life. Pöpe one day asked the doctor attending him what was the arm which seemed to come out of the wall. Byron occasionally fancied he was visited by a spectre, but regarded it as the effect of an overstimulated brain. Goethe stated that one day he saw the exact counterpart of himself coming towards him. These are but a few out of many instances in the lives of great men in whom the existence of hallucinations seems to have been well established by the evidence of the facts. Hallucination should be defined as a subjective perception, a perception without a corresponding objective

stimulus. Hallucinations of hearing are those which we meet with most frequently among the insane. They vary in character from simple noises, rumblings, moanings, hissings, whistlings, tinklings, musical sounds, barks, growls, cries, to the most complex of words and sentences. Hallucinations of sight may assume the most diverse forms. The most elementary appear as mere blurs, clouds, sparks, flashes of light, while, in the more complex, faces, persons, every variety of object and scene may be portrayed in detail. Sometimes they are very indefinite, colorless, and phantomlike; at other times they are very vivid, highly colored, and stand out in bold relief. Hallucinations of smell are not at all uncommon, and patients often complain that they smell poisonous gases, chloroform, iodoform, fæces, putrefying substances, dead bodies, seminal discharges, etc. Hallucinations of taste also occur, as when the patient tells us that he detects poison, blood, fæces, etc., in his food. Hallucinations of touch may be referred to any point in the body. They vary in character and intensity from creeping, pricking, cold, and burning sensations, to electric shocks, caresses, stabs, blows, bites, and injuries of all kinds. The author reviews the theories about hallucination. He believes that the theory of the peripheral origin of hallucination holds good in some, but not in all, instances. Even when the primary stimulus occurs within the cerebrum, hallucinations are produced only after the sensory centres, which are the seat of images, have been stimulated. A hallucination is never an entirely new creation of the brain, but simply a reproduction of memory images, and, in cases where the hallucination seems new, strange, and enigmatical, we have to deal merely with a new combination of its component elements. So also in dreams, which are the hallucinations of the sleeping state. It is an interesting and remarkable fact that hallucinations vary in different races and at different periods of history according to the knowledge and the dominant ideas of the day and the people. The ancient Greek who had visual hallucinations saw gods and goddesses, satyrs, driads, and nymphs. The hallucinated individual of the middle ages had visions of saints and guardian angels, or saw the devil, after the manner of that day, with horns, a goat's head, an arrow headed tail, and a pitchfork. In these later days visions of heaven or hell are more Miltonic in character, and with the wider diffusion of knowledge and the practical tendencies of advancing civilization they are becoming less frequent and less definite than they used to be. So, too, in the case of auditory hallucinations. In earlier times the hallucinatory voices were interpreted as those of celestial beings or spirits. Then the introduction of speaking tubes afforded a new explanation, and the sufferer was convinced that a secret system of tubes existed in the walls of his apartments. The introduction of the telegraph and then of the telephone was followed by the transference of the voices to wires hidden in the walls, while in these days it is no uncommon thing to find the victim of auditory hallucinations who declares that he is constantly receiving marconigrams and wireless messages. The author concludes that no doubt a hallucination is an abnormal cerebral product, and if it were possible

to divide mankind into two categories, those of sound mind and those of unsound mind, we should have no option left but to include the hallucinated with the unsound. Such a division is, however, impossible. Sanity and insanity are comparative terms. Each individual has a normal peculiar to himself, and applicable to none other. Any attempt to make a division between sanity and insanity must be artificial and conventional in the highest degree. The existence of hallucinations is certainly no criterion of insanity. We can, however, agree that when the subject of hallucinations fails to recognize these as anomalous productions of his brain, and allows his thoughts to be directed from their ordinary course, and his conduct to be regulated by the hallucinatory mental content, he is no longer of sound mind.

### Proceedings of Societies.

#### SOUTHERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.

*Twentieth Annual Session, Held in New Orleans,  
December 17, 18, and 19, 1907*

The President, Dr. HOWARD A. KELLY, of Baltimore, in the Chair.

*(Continued from page 90.)*

**Fracture of the Femur in Forcible Delivery.**—Dr. CHARLES R. ROBINS, of Richmond, said the possibility of fracture of the femur in the various manipulations of the lower extremities in forcible delivery was mentioned in medical literature, but he had been unable to find anything on the treatment. He was convinced from inquiry that such fractures were more common than the scant mention would indicate, and that successful treatment offered serious difficulties. The splint which he presented had been designed for the purpose of treating such a fracture occurring in his own practice, and the result obtained had been perfect. In the treatment of such a fracture it was absolutely necessary to adopt some method that would permit handling of the child for nursing without disturbing the limb, that would permit changing of napkins, that would prevent soiling, and that would not excoriate the delicate skin. These indications could not be met by any of the methods in vogue for treatment in older persons. The splint he described in detail, also its application.

**Some Results of the Hodgen Splint Treatment of Fractures of the Thigh as Shown by the X Rays.**—Dr. GEORGE S. BROWN, of Birmingham, demonstrated by means of sketches the changes he had made in the original splint of Hodgen as the latter had modified it from the old Smith's anterior splint. These changes were: First, he used one piece of cloth as a hammock to take the place of the underlapping strips of roller bandage, which were troublesome about rolling up in strings and otherwise getting out of order. Again, he had placed small tent blocks on the supporting cords by means of which the level and hang of the limb in the splint could be adjusted in a most satisfactory manner. Again, he had placed two wire loops at the distal corners of the wire frame, through which were passed the traction strips of muslin, which were pinned to the traction adhesive strips at the malleoli; these, be-

ing passed through these loops, were tied together across the sole of the foot, thus holding the limb firmly in the frame and doing away with the foot block which was formerly used, as in Buck's extension. The loops of the small suspension cords were hung upon the hook of a spring scales, which in turn was hung to the sash cord that went over the pulley wheel in the ceiling.

The writer maintained that while the limb was swung up from the bed and the suspension cord was at an angle, the pull was sure to be constant, and that this splint was the only apparatus so far devised that would give a constant pull. He asserted that the principle that should be followed in the treatment of fractures should be that of gradual reduction by a moderate pull steadily but constantly maintained, under which the muscles would entirely give up their resistance. Reduction under ether was unnecessary and useless, as the muscles would quickly recover their resistance and undo all that had been done in this way; the old Hodgen splint operated on the same principle, but owing to its crudeness would not stay in order, could not be properly regulated as to the pull, could not be properly balanced, and was not so comfortable. Buck's apparatus was painful, and for that reason the patient was constantly making efforts to have the weight removed long enough to allow him occasional relief from the strain on the hamstring tendons, and this kept the muscles alive and resistant, and, as long as the muscles were alive and resistant, it was practically impossible to overcome the shortening in an oblique fracture; but with the Hodgen, the muscles were put completely at rest in from a week to ten days.

The essayist showed a number of skiagraphs taken from old patients of his, most of whom had been treated some years before the discovery of the x ray. In all but two of the pictures the results were excellent, and these, he explained, had not had the advantage of proper treatment. Two pictures of fractures through the great trochanters showed union so perfect as to leave nothing more to be desired, and the same could be said of several fractures of the shaft. In summing up, it could be said of this splint that after it was put on a limb it was well nigh automatic in its operation. It was so comfortable that patients never objected to it in any way. It made less work for surgeons and nurses by at least 75 per cent. than any other means of treatment of these injuries, and the results were always excellent or fairly good.

**Practical Points in the Treatment of Fractured Femur.** Dr. W. P. CARR, of Washington, said that numerous surgeons had advocated wiring or some open operation in all or nearly all fractures of the femur, and maintained that perfect results could not be obtained without it. Results could be obtained in nearly all cases of simple fracture that were both functionally and anatomically perfect, if the following points were carefully observed: Extension by weight and pulley or other efficient means must be used daily. The shortening must be absolutely overcome in the first twenty-four or at most thirty-six hours, or it could never be entirely overcome. From ten to twenty-five pounds weight would be required to do this, and there should be great care to see that the weight was effective. Shortening was due to faulty application of the weight or too little

weight. Catching of some part of the apparatus on the foot of the bed or in the mattress or bed clothing, and slipping down in bed, were the most common defects. The traction should be applied so as to tend to lift the heel and not pull it down against the mattress, as so commonly happened. Slipping down was best prevented, not by elevating the foot of the bed, but by elevating the lower half of the mattress to an angle of twenty degrees. In fractures just below the lesser trochanter, the elevation should be thirty-five or forty degrees, flexing the thigh to that extent, and the limb should be abducted slightly. Compound fractures should, as a rule, be wired, as the wound was usually contaminated and the chances of suppuration were lessened by an open operation and thorough cleansing of the parts. Children were best treated by vertical extension. All shortening could be absolutely avoided by care during the first few days. Careful measurements should be made, and skiagrams, when possible. Any fracture not in satisfactory position at the end of a week should be wired. If simple rules of mechanics were observed, a single small loop of soft iron wire was all that would be needed to prevent shortening, lateral displacement, or rotation. Iron wire was much stronger than silver. Angular deformity must be prevented by traction, a plaster of Paris cast, or splints, no matter what method of fastening the bones was used.

Three instruments were shown that had proved very useful in resecting and wiring bone: First, a modification of Wyeth's bone saw, much simpler and more effective than Wyeth's. Second, a bone drill made like a small brace and bit, to be used in one hand while the other hand was free to hold the bone. Third, a very small, thin, grooved director, small enough to pass through the drill hole and guide the wire. This was very useful in passing the wire from within outward through the second fragment, especially when oozing of blood obscured the opening of the drill hole.

**The Relaxed Knee Joint and Its Treatment.**—Dr. ALBERT H. FREIBERG, of Cincinnati, called attention to a group of cases involving the knee joint which, on account of the absence of manifestations in the radiogram, the absence of any infectious element, and most often the absence of any organic change in the joint to be appreciated by physical examination, had for the most part been considered functional. Excluded from this consideration were the cases with knee symptoms proceeding from weak and flat foot. The complaint of the patient in these cases was either that of joint pain largely or altogether dependent upon function, with occasional effusion into the joint after unusual exertion, or else the occurrence of sudden attacks which were frequently very similar to those resulting from injury to the meniscus. In the latter cases there was the sudden onset of very sharp pain, so that the patient often fell. This was commonly followed by an effusion, which subsided after a few days, leaving the joint apparently normal. The chief clinical characters, aside from these symptoms, were atrophy of the quadriceps extensor of the thigh and diminished power of extension of the knee consequent thereon. This atrophy was to be determined by accurate measurement with the tape line. Since the quadriceps was normally the tensor of the knee joint, it was

relaxation permitted its falling into folds, and it was thus subjected to frequent injury by being pinched between the femur and tibia, and the symptoms were thus explained. Villous hypertrophy might ensue in consequence of the repetition of these attacks. In all the cases reported it was possible to determine a traumatic origin, although in several the injury appeared to be slight. The theory of reflex atrophy was favored rather than that of inactivity, because in several cases the limb was used without any intermission after the injury. The description of this class of cases as "relaxed knee joint" was advocated as a distinct syndrome and not simply as a feature of villous arthritis. The treatment consisted of measures to restore the volume and strength of the quadriceps, such as suitable gymnastic exercise, resisted movements, massage, and electricity. Tone must be restored to the relaxed capsule by suitable local measures, such as hydrotherapy, etc. Often the return to the normal was so slow that the assumption of damage to the central nervous system seemed justified. All patients might, however, be expected to recover with proper treatment and sufficient perseverance.

In summarizing, the author stated that many cases of so called functional knee symptoms were due to reflex atrophy of the quadriceps following injury. The term relaxed knee joint should be reserved for such cases. The injury might be so slight that its ætiological relation was overlooked. The atrophy following injury could in many cases not be explained by the theory of inactivity. Cure of these cases would be brought about by the restoration of the normal volume and strength of the quadriceps extensor. In some cases recovery was so protracted as to warrant the belief in material damage to the central nervous system. While in such cases endeavors were necessarily limited to treatment at the periphery, ultimate recovery might be expected to follow persevering and well directed efforts.

**Abdominal Cæsarean Section.**—Dr. HENRY D. FRY, of Washington, discussed the management of labor in minor degrees of pelvic contraction, with special reference to the relative indications for abdominal Cæsarean section. He tabulated eighteen cases of Cæsarean section.

**The Treatment of Diffuse Suppurative Peritonitis.**—Dr. STUART MCGUIRE, of Richmond, Va., reviewed the work of Muscatello, Clark, Fowler, Bond, Cannon, and Murphy, and stated that the present generally accepted method of treatment had not been adopted empirically, but was the result of deductions from scientific observations. A recent analysis of the last five hundred cases of operations for appendicitis in his private hospital gave a record of twenty-four patients with diffuse suppurative peritonitis. The first six were treated by the old method of irrigation and multiple drainage, with five deaths; the last eighteen were treated by the so called Fowler-Murphy method, with but one death. The difficulty he had experienced in carrying out the treatment was in maintaining the patient in an exaggerated Fowler position. He found by visiting other hospitals that two principles were in practice, angulation of the patient and angulation of the bed. The first was effected by keeping the bed horizontal and elevating the body of the patient by means of a shoulder rest; the second by elevating the head of the bed

and allowing the patient to lie flat on the inclined mattress. The advantage alleged for the semisitting position over bed elevation was that it gave better drainage, but this he did not believe to be true, as it was impossible to maintain the patient in the proper position on a shoulder rest, while it was an easy matter to prevent his slipping on an inclined mattress. The disadvantages of the semisitting position were that it made it difficult for the nurse to handle the case, that it was attended by muscular tension and fatigue, and that the patient would slip down so that his body would bend at the costal arch and his abdomen would be on a plane parallel with the surface of the bed. The advantages of elevating the head of the bed were that the mattress might be put at any angle, that the patient lay on the flat surface, often unconscious of his position, and that he was completely relaxed and easily nursed.

Dr. McGuire exhibited a model and photographs of an apparatus which he had employed for more than a year to elevate the head of the bed and to prevent the patient's sliding down the incline. The bed elevator consisted of a wooden base and upright piece, with notches on its side. An iron link supported a block, which received the leg of the bed. When horizontal, it would slip up or down, but when oblique would catch in one of the notches. The bed seat consisted of a board which made a shelf on which the patient sat. A wooden shaft projected downward and passed through a second board, which rested against the footpiece of the bed. In the shaft were a number of holes, and a peg placed in one of them would prevent the shaft passing through the bottom board, and thus transfer the weight of the patient to the foot of the bed.

**Pulmonary Embolism.**—Dr. WILLARD BARTLETT and Dr. R. L. THOMPSON, of St. Louis, went into the history of the circulation of the blood, thrombosis, and embolism. They discussed the various reasons why thrombus formation took place, stating that it was most common in neighborhoods rich in venous blood. An embolus might float off if there were such thrombi and cause instant death if it plugged the pulmonary artery or one of its main branches, but if the clot was small and lodged in a small lung vessel, no symptoms at all might be seen. Attention was called to varicose veins conducting the blood from large abdominal tumors, and the object of the paper was their recognition and treatment. Thrombus formation had attended as high as 5 per cent. of certain long series of operations, while 2 per cent. of the same were attended with fatal pulmonary embolism.

The authors reported twenty-two cases, sixteen of them surgical. An autopsy was performed in the majority of the twenty-two. Pulmonary embolism occurred in these cases at intervals varying from one to twenty-eight days. Two of their patients recovered, but twenty died, the interval between the onset of pulmonary symptoms and death varying from a few seconds to twelve hours. The symptomatology was considered, as was also the prophylactic treatment.

**The Diagnosis of Extrauterine Pregnancy.**—Dr. H. J. BOLDT, New York, read a paper on this subject. Under the term extrauterine pregnancy he included all gestations which were situated outside

the uterine cavity. While, anatomically, extrauterine pregnancy might be divided into several varieties, from a clinical point of view such a distinction was not essential. Tubal pregnancy was the most frequent form of ectopic gestation. Uninterrupted extrauterine pregnancy was but rarely recognized, and then usually by mere accident when operating for other conditions, or when examining a patient for a complaint causing symptoms independent of extrauterine gestation. He had never palpated in a case of tubal pregnancy prior to the occurrence of symptoms due to the pathological implantation of the ovum, except in one instance, a double tubal gestation. In this case, however, the right tubal gestation gave rise to symptoms and was diagnosed. On the opposite side a tubal enlargement was felt, the nature of which was not diagnosed, but on operation the tubal distention proved to be due to a tubal pregnancy which had not begun to be interrupted by bleeding within the tube or by any inflammatory process about the tube. The distention was limited to the outer two thirds of the tube, which was freely movable and did not possess the doughy feeling of a pyosalpinx or the tense elasticity of a hydrosalpinx, which he had supposed to exist on that side. The symptoms were divided into subjective and objective, and these were discussed at length.

The absence in the history of the passing of a decidua did not exclude the presence of ectopic gestation. In the large number of extrauterine pregnancies the author had seen—nearly three hundred—less than one half gave an affirmative history on this point. A decidua might be passed unnoticed, or it might remain in the uterus and eventually be transformed into normal endometrium.

After considering the diagnostic features of early extrauterine pregnancy, the author pointed out that after the second half of the gestation period the diagnosis depended on one's ability to determine the presence of a fetus outside of the uterus, which was, as a rule, not very difficult, unless the fetus was located between the folds of the broad ligament, and the woman had thick abdominal walls, or the fetus had been dead for some time and was not in close contact with the abdominal parietes or the cul-de-sac of Douglas. At this period of gestation the history would aid very much, because in nearly all cases, in addition to the symptoms that were present in the early stages of ectopic pregnancy, there were also in the history symptoms which showed that one or more attacks of local or even general peritonitis had occurred.

A pregnancy in the interstitial part of the Fallopian tube caused bulging of the uterine cornu of the invaded side. This bulging, being in an upward direction, necessarily made the cornu much higher than that on the opposite side, and the annexa were given off at a much lower plane than that of the impregnated side. In the event of rupture, which nearly always occurred during the first half of the gestation period, sometimes before the end of the second month, the hemorrhage was very profuse and required rapid intervention. The diagnosis was based upon the determination of pregnancy, with the appreciation of the local findings.

Pregnancy in one horn of a bicornuate uterus should not cause difficulty in diagnosis if the pregnancy had gone to the fifth month or more and the

fetus was still living. During the first half of gestation, in addition to the subjective symptoms of pregnancy, one should ascertain the presence, alongside the nonimpregnated cornu, of the impregnated cornu, which was of a doughy consistency, unless the fetus was dead. In such event, the impregnated uterine horn became harder and more globular, so that it might be mistaken for a pedunculated myoma or perhaps an ovarian cyst. But if one took all factors into consideration, the history and the objective symptoms to be found on bimanual examination, the diagnosis should not be difficult under ordinary circumstances. It might, however, be quite difficult if the patient was corpulent and had rigid abdominal walls.

The greatest difficulty in making a correct diagnosis was in distinguishing an ectopic gestation in its early stages from purulent inflammatory conditions of the annexa, because in the latter the patients sometimes gave a history identical with that of ectopic gestation, and objectively the tube was distended and firm in consistence. Also the change in the uterus and in the vaginal mucous membrane might be similar. We might have the delayed or omitted menstruation, or atypical bleeding, and he had seen two cases where the blood was similar to that described as typical for the bleeding of interrupted extrauterine pregnancy. Furthermore, the character of the pain was sometimes identical, except that no collapse ever followed, as in profuse hemorrhage. He frankly confessed that occasionally in such cases he had been unable to make the diagnosis without surgical intervention.

The error most frequently made by physicians was that of mistaking ectopic gestation for early abortion. Of his ectopic gestation patients, who had been curetted by their attendants, more had been so treated under the impression that they had had an incomplete abortion than for any other erroneous diagnosis. In taking the history it would be found that with abortion cases the pains usually began with a moderate aching or drawing pain in the lumbar region, radiating toward the hypogastrium. In tubal pregnancy the pains were much more intense and were unilateral in the beginning, and the periods of intermission were generally further apart.

Appendicitis might sometimes be mistaken for extrauterine pregnancy, or the opposite error might occur. In an inflammation about the appendix, however, the exudate, if there was one, would be higher up in the pelvis, more toward the iliac fossa. Furthermore, there was always a febrile condition in appendicitis, and none of the symptoms of pregnancy were found unless pregnancy and appendicitis were coexistent. Besides, if one was careful in eliciting a patient's history, there would always be found a difference.

**Renal Decapsulation for Chronic Parenchymatous Nephritis.** Dr. J. C. OLIVER, of Cincinnati, presented a report of the case of a young man upon whom decapsulation of both kidneys had been practised for the relief of chronic parenchymatous nephritis. The patient received medical treatment alone for a period of about eight months. At the expiration of that time his condition was much worse than it was at the time he began treatment. In fact, his condition was apparently desperate when a resort to surgical intervention was determined upon.

Decapsulation was practised on December 9, 1905. The first favorable sign following the operation was an improvement in vision on the sixth day. The average secretion of urine prior to the operation was from four to fifteen ounces in twenty-four hours. He passed nineteen ounces the day following the operation, and by the end of a week this amount had increased to fifty ounces. The preexisting general œdema diminished so rapidly that at the end of two weeks one could notice a very decided reduction in the amount. A marked increase in the percentage of urea excreted was associated with the augmented excretion of urine, but the percentage of albumin remained high. This period of improvement was followed by one of relapse. The œdema increased rapidly, and repeated tapplings were necessary. The heart exhibited symptoms of gradual dilatation, and there were almost nightly attacks of severe dyspnoea. The patient was very ill during January, February, and March, 1906. It became necessary to aspirate both sides of the chest six or seven times during this period. The patient became so desperately ill that his demise was looked for almost daily. A marked improvement took place in his condition about the 1st of April. The dyspnoea diminished, the urine increased in quantity, the œdema disappeared entirely, and the patient was able to get up and walk about. The amount of albumin in the urine diminished, and the casts were very much fewer and less granular. The patient was dismissed from the hospital on June 8, 1906. During the period from June to October he continued to improve, and he gained in strength to such a degree that he was able to do some light work. There was but little further gain in the eyesight after the primary improvement. The patient was suddenly taken ill during the first week in October. He became comatose, remained in that condition, and at the end of three days expired. There was no return of dropsical conditions. The death was in all probability attributable to the deranged heart.

**Inoperable Sarcoma of the Neck.**—Dr. OLIVER reported a case of inoperable sarcoma of the neck which was apparently cured by a combination of the use of Coley's toxins with exposure to the action of the Röntgen ray. The treatment extended over a period of five months, at the conclusion of which the tumor masses had entirely disappeared. Nineteen months after the apparent cure a small nodule appeared in the right parotid region. The patient was now receiving injections of the toxins in the hope that these newer manifestations might also prove amenable to the treatment.

(To be concluded.)

### Book Notices.

*Pathologische Physiologie; ein Lehrbuch für Studierende* von Dr. EDUARD KREHL, a Professor und Direktor der medizinischen Klinik in Heidelberg. Mit einem Beitrag von Professor E. LEVY in Strassburg. Fünfte neu bearbeitete Auflage. Leipzig: F. C. W. Vogel, 1907. Pp. 649.

We have had occasion to call attention to Krehl's work on pathological physiology on the appearance of four of its previous editions. Like many German works of this class, a new edition is in reality a new edition, and additions, corrections, and re-

writing are apparent, making the work one brought up to date in verity.

The anatomicopathological point of view regarding disease has had its great advantages. It has systematized our knowledge and brought order out of chaos. Bacteriological science has added its quota to a better comprehension of ætiological factors, while chemistry has led to the interpretation of modifications in the underlying laws that govern many of the life processes. These combined have made an enlightened pathological physiology a possibility.

That a time has arrived when disease must have a wider interpretation in terms of function is evident from the great success that Krehl's work has already had, and for years no work of its compass has appeared in which the essentials of morbid physiology have had a more illuminating light thrown upon them, or a deeper or more comprehensive grasp been shown of the chief factors which make for disease. It is a book to be most cordially commended to medical student, general practitioner, and specialist alike.

*Zur Psychologie und Therapie neurotischer Symptome. Eine Studie auf Grund der Neurosenlehre Freuds.* Von Dr. ARTHUR MUTHMANN, II. Arzt des Kurhauses Bad Nassau, früherem II. Arzt der psychiatrischen Klinik der Universität Basel. Halle a. S.: Carl Marhold, 1907. Pp. 115.

The author gives as his reason for publishing this small monograph the good results which he believes he has obtained with the use of the Freud psycho-analytical method in the Basel Psychiatric Clinic. He further believes that, as the amount of literature bearing upon the method is still very slight, his contribution will not fall within the class of discussions already done to death.

He devotes the major portion of the work to the setting forth of the histories of a number of patients who by means of the Freud method are willing or compelled to unburden themselves of much that has been kept hidden in their life experiences. Most of them are hystericals, and the main thesis discovered is truly Freudian, namely, the psychical effects of the sexual life.

We have always felt that Freud made a partial if not complete wreck of his scientific craft when he ran upon the rock of the sexual causation of all neurotic ills. 'He still remains upon this isolated island of interpretation, and his followers are not few.' Muthmann's contribution is an interesting one on what might be more rigidly interpreted as a study in the variations and aberrations of sexual feeling, and it can be alleged for it that it furnishes another book on that region of psychic life which has ever challenged the attention of the "Peeping Toms" of the medical world.

Such analyses are no doubt valuable in obtaining information, one sided though it may be, of the natural history of the sexual life, but they err, in our opinion, and the present volume emphasizes this defect, erroneous in assuming that the ultima Thule has been reached the moment that sexual doings have been overturned and exposed to the view of the curious analyzer.

The part of the work which is specially valuable, however, and taken in its entirety it is a small

monograph of real service, is the very able summary of the various avenues of psychotherapeutic research which have been developed of late years.

*Die Lokalanästhesie, ihre wissenschaftlichen Grundlagen und praktische Anwendung.* Ein Hand- und Lehrbuch von Dr. med. HEINRICH BRAUN, Direktor des königlichen sächsischen Krankenstiftes in Zwickau. Zweite, teilweise umgearbeitete Auflage. Mit 128 Abbildungen. Leipzig: Johann Ambrosius Barth, 1907. Pp. 452.

This book has seen two editions in two years, a circumstance which speaks well for its contents. The history of local anaesthesia is given in Chapter I, followed by the physiology of sensibility and pain and local anaesthesia and its methods in Chapter II, while Chapter III and IV treat of local anaesthesia produced by compression of nerves, anaemia, and cold. Chapters V and VI lead up to Chapter VII, dealing with the chemical compounds used in local anaesthesia. Cocaine, as is only natural, receives a lengthy discussion, and the subject is followed by tropacocaine, eucaine, holocaine, aneson (anesin), orthoform, nirvanin, anaesthesin, subontin, stovaine, alypin, novococaine, etc. Chapters VIII and IX treat of other methods of producing local anaesthesia, such as the mechanical, the use of suprarenin and electricity, medullary anaesthesia, etc. The indications, contraindications, and technique are treated of in Chapter X, while in Chapter XI to XVII are considered the operations that can be conducted under local anaesthesia. Very instructive and giving a brilliant testimony of the thoroughness of the author is the literature for the first nine chapters, running in small type over thirty pages, followed by an index giving the names of authors and a general index.

*Elements of Human Physiology.* By ERNEST H. STARLING, M.D., Lond., F.R.C.P., F.R.S., Jodrell Professor of Physiology, University College, London. Eighth Edition. Chicago: W. T. Keener & Co., 1907. Pp. viii-716. (Price, \$3.75.)

Professor Starling's *Elements of Human Physiology* has been a handy manual for a number of years. The present edition has been little changed from the previous one, the seventh, but the book has been fully brought up to date.

It is a book which will find its proper place, not only on the desk of the medical student who follows up the knowledge he has received in the lecture room by reading at home, but also on the shelves of the practitioner, who will quite often find it necessary to refresh his memory.

*Atlas and Textbook of Human Anatomy.* By Dr. JOHANNES SOBotta, Professor of Anatomy in the University of Würzburg. Edited with Additions, by J. PLAINFAIR McMURRICH, A. M. Ph. D., Professor of Anatomy in the University of Toronto, etc. Volume III, Vascular System, Lymphatic System, Nervous System, and Sense Organs. With 297 Illustrations, Mostly in Colors. Philadelphia and London: W. B. Saunders Company, 1907. P. 342. (Price, \$6.)

This last, third, volume has kept what the first two promised. As was to be expected, the book is much larger than the preceding two (vol. I, 258 pages; vol. II, 194 pages; vol. III, 342 pages). It portrays the vascular, the lymphatic, and the nervous systems, and the sense organs.

The author also gives his reason for including in one volume arteries, veins, and nerves; and describing the heart with the viscera in another volume. He says: "Long years of experience in the dissect-

ing room have led the author to depict the peripheral nerves and bloodvessels as the student is accustomed to see them in the cadaver, i. e., the vessels and nerves together in the same region. . . . (Thus) the student using the atlas in the dissecting room can find upon a single page the description of the great majority of the structures found in a layer of his dissection, and is not forced to hunt through the volume and waste much time in unnecessary search."

This reason seems to be a good one, although we still believe that the 110 pages devoted to the vascular system added to the second volume would have given the volumes a more uniform size and brought this system, with the heart, into one book. (See *Journal*, lxxxv, page 381.)

The coloring of the plates is excellent. The method of distinguishing the parts of the body has been carried out systematically, as was done in the preceding volumes. Thus, the arteries are colored red, the veins blue, the nerves bright yellow; in the brain red illustrates the pyramidal tract, violet the occipitotemporal cerebropontile, and blue the frontal cerebropontile. A beautiful reproduction is given in Fig. 623, representing the base of the encephalon.

Two short addenda are added. Appendix I gives in four pages a condensed account of the regions of the human body, and Appendix II, in three pages, gives general remarks concerning the structure and early development of the human body.

*Technischer Fortschritt und seelische Gesundheit.* Akademische Antrittsrede gehalten am 25. Juni 1906. Von WILLY HELLPACH, Dr. med. et phil. Privatdozent der Psychologie. Mit einem Geleitwort vom Bildungswert der Psychologie. Halle a. s.: Carl Marhold, 1907. Pp. 30.

In this lecture Hellpach calls renewed attention to a question which was eagerly debated by the Athenians, and if the code of Hammurabi is evidence, by the ancient Babylonians. In it, however, he seems to deal with the problem as though it were entirely new and a creation of modern environment forced upon mankind by the sudden blossoming out of technical processes in all avenues of enterprise.

Neurasthenia and hysteria are on the increase in far greater proportion than the natural increase in population would seem to warrant. Modern machinery, railroads, electricity, telephone, the clang-clang, and hustle and bustle of modern industrial activity are responsible for the widespread increase in nervous irritability. This, in short, is the general line of argument of the writer. But, while outlining what he believes are real facts, and their essential relationships to the causes which he depicts, he maintains a fairly conservative and optimistic attitude toward the future and the possibilities of the sound nervous system "to stand the racket" and to evolve higher and better forms of nervous stability in the face of the wearing factors that are bound to increase unless the race has reached its acme.

He pays a passing compliment to certain "captains of industry" who reach the top by a ruthless disregard of all ethics and morality, counting themselves above the laws made for the common people—a point of view quite widely held and displayed by the robber barons of the feudal times.

He makes a final plea for better methods of nervous and mental hygiene and for the physician mind healer along rational and temperate psychological lines. The essay contains little new, but is a careful summary of conditions which must be met by the neuropsychiatrist in the present and in the future.

### Miscellany.

**Resolution on the Death of Dr. Henry P. Loomis.** The following resolution was adopted by the Board of Trustees of Bellevue and Allied Hospitals at the meeting on December 31, 1907:

Whereas, The Board of Trustees of Bellevue and Allied Hospitals has learned with profound regret of the death of Dr. Henry P. Loomis, for many years one of the attending physicians to Bellevue Hospital, be it therefore

Resolved, That the board desires to place on record its sense of the value of Dr. Loomis's services to the patients he has treated within the walls of Bellevue Hospital, as well as his more extended services

to the cause of medical science in general; and be it further

Resolved, That copies of this resolution be forwarded to his family and to the medical journals of the city of New York. JAMES K. PAULDING,  
Secretary Board of Trustees.

**Report of the Committee on the Classification and Treatment of Mentally and Physically Defective Children.**—The committee of the Medical Society of the County of New York made the following report, classifying the defective children as physical and mental defectives, which was presented and adopted at the regular meeting, held on November 25, 1907:

**Physical Defectives:** Under the present system the Department of Health has medical oversight of the public schools, especially directed to the detection of communicable diseases. Physical defects are noted as they are discovered in the course of the routine examinations and many defective children are referred to physicians; and it is probable that the physical needs of the children are as well cared for as could be expected under existing conditions. These points seem worthy of suggestion, however: There should be an adequate method by which each child is examined and recorded on admission to school; the record should contain a statement of the condition as diagnosed by the medical inspector, (or of the vision, as noted by the teacher,) the treatment and its results; so that it would be available for the principal or teacher and for the medical inspector in order that the future progress of the child and his attendance may be controlled. In cases where children are sent to physicians or dispensaries for treatment, the medical profession can aid the school authorities by noting, briefly, on a card which should be provided for the purpose by the school authorities, whether the disease is contagious or not, and such facts as will aid the teacher in showing a proper consideration for the child, as when hearing or vision is defective. The termination of treatment should also be noted so that the child may be readmitted to the school without unnecessary loss of time. Until a definite census of the physical defects of school children is obtained, with information regarding the adequacy or inadequacy of present methods of meeting such defects, hasty action of a paternal nature, by the city or State authorities is not favored by the committee, but it is the expression of this committee that there is a proper economic standard for this work as children who are physically defective are less liable to be charges on the community if their physical weaknesses are corrected.

**Mental Defectives:** The public school system has been unable as yet to adequately provide for the increasing number of mentally backward and deficient children. Such children are unable to benefit by the regular school instruction and it is an injustice for the normal children to associate with these mentally backward and deficient children. In many European countries supplemental schools are in successful operation.

In view of the foregoing the committee would suggest:

First. That under the supervision of the Board of Education a census and record of the mentally

backward and deficient children in the schools of New York shall be made.

Second. That a paid Commission or Department of Mental Hygiene should be formed under the supervision of the Board of Education, to examine and classify the mentally backward and deficient children. This department or commission should comprise at least two recognized neurologists. The commission or department shall classify all new pupils and at stated intervals reclassify them. The commission or department shall be empowered to remove for institutional care and training all those mentally defective children who have shown themselves unteachable or incapable of such instruction as to render them ultimately selfsupporting. The commission or department, as a body should have power to reinstate in the regular school for normal children those pupils of the ungraded classes whose mental condition has improved sufficiently to warrant the transfer. The commission or department should outline the organization, equipment, teaching, personnel, and general management of these supplemental schools for mentally backward and deficient children. Idiotic and imbecile children should be regarded as ineligible for these supplemental schools; they should be at once transferred to State institutions for this class.

We are aware that these suggestions are in part in process of being acted upon by the Board of Education. The suggestions are made only to assist and further organize the plan of special schools for the backward and mentally deficient children in the New York school system.

## Official News.

### Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon general, United States Public Health and Marine Hospital Service, during the week ending January 10, 1908:

Smallpox—United States.			
Place.	Date.	Cases.	Deaths.
California—Berkeley	Dec. 14-21	1	1
District of Columbia—Washington	Dec. 14-28	4	0
Illinois—Springfield	Dec. 14-28	3	0
Indiana—Ellettsville	Dec. 14-28	3	0
Kansas—Lawrence	Dec. 11-28	17	0
Massachusetts—Boston	Dec. 14-28	1	0
Minnesota—Winona	Dec. 21-28	2	0
Missouri—St. Louis	Dec. 14-28	5	0
New York—New York	Dec. 14-28	7	0
North Carolina—Savannah	Dec. 14-28	1	0
Tennessee—Knoxville	Dec. 21-28	1	0
Tennessee—Nashville	Dec. 14-28	1	0
Washington—Spokane	Dec. 14-28	2	0
Smallpox—Foreign.			
Argentina—Rosario	Dec. 14-28	1	0
Brazil—Rio de Janeiro	Dec. 14-28	16	11
China—Hongkong	Dec. 14-28	34	14
Colombia—Buenos Aires	Dec. 14-28	3	0
Cuba—Havana	Dec. 14-28	1	0
France—Paris	Dec. 14-28	9	0
Germany—Berlin	Dec. 14-28	2	0
India—Madras	Dec. 14-28	6	0
Italy—Genoa	Dec. 14-28	143	0
Japan—Kobe	Dec. 14-28	66	0
Japan—Yokohama	Dec. 14-28	1	0

Java—Batavia	Dec. 14-28	3	0

### Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the fourteen days ending January 8, 1908:

AMESSE, J. W., Passed Assistant Surgeon. Temporarily relieved from Havana, Cuba, and directed to proceed to Washington, D. C., for assignment to temporary duty in the Hygienic Laboratory.

ATILES, P. DEL V., Acting Assistant Surgeon. Granted leave of absence for thirty days from January 6, 1908.

BARNES, W., Acting Assistant Surgeon. Granted leave of absence for nine days from January 1, 1908.

BELL, J. M., Pharmacist. Granted leave of absence for eight days from January 1, 1908.

BROWNE, R. W., Acting Assistant Surgeon. Granted leave of absence for two days from December 23, 1907, under paragraph 210, Service Regulations.

FRANCIS, E., Passed Assistant Surgeon. Granted leave of absence for five days from December 31, 1907.

FRICK, JOHN, Acting Assistant Surgeon. Granted leave of absence for five days from January 1, 1908.

FROST, W. H., Assistant Surgeon. Granted leave of absence for one day.

GARDNER, C. H., Passed Assistant Surgeon. Leave of absence, granted for one month from December 6, 1907, revoked.

GOLDBERGER, JOSEPH, Passed Assistant Surgeon. Directed to proceed to Reedy Island Quarantine Station for special temporary duty; upon completion of which to rejoin his station at the Hygienic Laboratory.

HERRING, R. A., Assistant Surgeon. Granted leave of absence for three days from December 29, 1907, under paragraph 191, Service Regulations.

HOLLAND, D. J., Acting Assistant Surgeon. Granted leave of absence for three days from December 29, 1907, under paragraph 191, Service Regulations.

KRISHN, EMB., Assistant Surgeon. Granted leave of absence for three days from December 6, 1907, under paragraph 191, Service Regulations.

LAVINOR, C. H., Passed Assistant Surgeon. Granted leave of absence for one month from January 1, 1908.

LIGHE, S. D. W., Acting Assistant Surgeon. Granted leave of absence for eight days from January 1, 1908.

LINTY, W. L., Acting Assistant Surgeon. Granted leave of absence for three days from January 1, 1908.

LUMSDEN, L. L., Passed Assistant Surgeon. Granted leave of absence for six days from December 24, 1907, under paragraph 191, Service Regulations.

LYALL, R., Acting Assistant Surgeon. Granted leave of absence for six days from December 23, 1907, under paragraph 210, Service Regulations.

MCCONNELL, E. E., Acting Assistant Surgeon. Granted leave of absence for thirteen days from January 1, 1908.

NUTE, A. J., Acting Assistant Surgeon. Granted leave of absence for nine days from December 23, instead of ten days from December 21, 1907.

RICHARDSON, S. W., Pharmacist. Granted leave of absence for seventeen days from January 1, 1908.

ROBERTSON, H. MCG., Passed Assistant Surgeon. Granted extension of leave of absence for ten days from January 4, 1908.

SCOFFIELD, R. B., Assistant Surgeon. Detailed as a member of the Revenue Cutter Service Retiring Board, New York, N. Y.

SIMONSON, G. T., Acting Assistant Surgeon. Granted leave of absence for two days from January 14, 1908.

SPRAGUE, E. K., Passed Assistant Surgeon. Leave of absence granted for seven days from December 31, 1907, revoked.

STANTON, J. G., Acting Assistant Surgeon. Granted leave of absence for fourteen days on account of sickness, from December 5, 1907.

STERN, S. O., Pharmacist. Granted leave of absence for seven days from January 1, 1908.

STONER, J. B., Surgeon. Leave of absence granted for ten days from December 31, 1907, amended to read seven days only.

THOMAS, J. N., Acting Assistant Surgeon. Granted leave of absence for twenty-six days from December 3, 1907, on account of sickness.

THOMPSON, W. R. P., Acting Assistant Surgeon. Granted leave of absence for nine days from January 1, 1908.

WARD, W. K., Passed Assistant Surgeon. Granted leave of absence for two days from December 30, 1907, under paragraph 191, Service Regulations.

WASDIN, EUGENE, Surgeon. Granted seven days' extension of leave of absence.

WATKINS, MCD., Acting Assistant Surgeon. Granted leave of absence for two days from December 26, 1907.

WETMORE, W. O., Acting Assistant Surgeon. Granted leave of absence for one day, December 17, 1907, on account of sickness.

WICKES, H. W., Passed Assistant Surgeon. Detailed as a member of the Revenue Cutter Service Retiring Board, New York, N. Y.

WILLIAMS, L. L., Surgeon. Directed to proceed to Crisfield, Md., for special temporary duty; upon completion of which to rejoin his station at Baltimore, Md.; granted leave of absence for ten days from January 8, 1908.

WILSON, J. G., Acting Assistant Surgeon. Granted leave of absence for one day, December 17, 1907, on account of sickness.

#### Board Convened

A board of medical officers was convened to meet at the Bureau in Washington, D. C., 10 o'clock a. m., Monday, January 20, 1908, for the purpose of examining candidates for the position of assistant surgeon. Detail for the board: Surgeon D. A. Carmichael, chairman; Passed Assistant Surgeon H. S. Mathewson, and Passed Assistant Surgeon J. F. Anderson, recorder.

#### Army Intelligence:

*(Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending January 11, 1908.)*

ASHBURN, P. M., Captain and Assistant Surgeon. Leave of absence extended one month.

FORD, J. H., Captain and Assistant Surgeon. Granted thirty days' leave of absence.

LA GARDE, L. A., Lieutenant Colonel and Deputy Surgeon General. Relieved from duty in the Philippines Division and arrived at San Francisco, Cal., ordered to report to the Adjutant General of the Army for further orders.

PARSONS, H. J., Major and Surgeon. Granted two months' leave of absence with permission to apply for another month.

SCHREINER, E. R., Captain and Assistant Surgeon. Upon arrival at San Francisco, Cal., will report in person to the commanding general, Department of California, for assignment to duty at the General Hospital, Presidio of San Francisco, Cal.

SHAW, J. H., Captain and First Lieutenant. Ordered to accompany 14th Infantry from Vancouver Barracks, Washington, to San Francisco, Cal.; upon completion of this duty granted ten days' leave of absence.

#### Navy Intelligence:

*Official list of changes in the medical corps of the United States Navy for the week ending January 11, 1908:*

BAKER, M. W., Passed Assistant Surgeon. When discharged from treatment at the Naval Hospital, New York, N. Y., ordered home and granted sick leave for one month.

JACOBSON, L. C., Acting Assistant Surgeon. Appointed an acting assistant surgeon from January 3, 1908.

SPEAR, R., Surgeon. Detached from the navy yard, League Island, Pa., and ordered to the *Relief*.

STOKES, C. F., Surgeon. Detached from the Bureau of Medicine and Surgery, Navy Department, and ordered to command the *Relief*.

## Births, Marriages, and Deaths.

#### Married.

BAKER-MILLER.—In Louisville, Kentucky, on Thursday, December 19th, Dr. Henry H. Baker and Miss Mamie C. Miller.

BAYLISS-WHEATLEY.—In Syracuse, New York, on Saturday, December 28th, Dr. Frank P. Bayliss and Miss Eva May Wheatley.

COLLIER-SMITH.—In New York, on Wednesday, January 8th, Dr. Hix Furbush Collier and Miss Janet Birdsall Smith.

CRAWFORD-STRATTON.—In Philadelphia, on Saturday, January 4th, Dr. E. Druitt Crawford and Miss Frances J. Stratton.

DEWAR-STRINGHAM.—In Unadilla, New York, on Monday, December 30th, Dr. Bennett W. Dewar, of Albany, and Miss Fannie L. Stringham.

FLETCHER-SECHRIST.—In Cleveland, Ohio, on Wednesday, January 1st, Dr. Hugh M. Fletcher and Dr. Cora Sechrist.

HAYES-CANAVAN.—In Holyoke, Massachusetts, on Thursday, January 2d, Dr. Justin E. Hayes, of Chesterfield, and Miss Josephine E. Canavan.

LAING-McLEAN.—In Gladstone, Michigan, on Tuesday, January 7th, Dr. A. L. Laing and Miss Mildred McLean.

MARVIN-SWIFT.—In New York, on Thursday, January 9th, Dr. Horace N. Marvin, of Dover, Delaware, and Mrs. Flora M. Swift, of Brookline, Massachusetts.

WILDER-ROTHSCHILD.—In Chicago, on Wednesday, December 25th, Dr. William H. Wilder and Miss Carrie Rothschild.

#### Died.

AUSTIN.—In Bedford City, Virginia, on Thursday, January 2d, Dr. G. W. Austin.

BAXTER.—In Lima, Ohio, on Sunday, January 5th, Dr. Samuel A. Baxter.

DRUMMOND.—In Calvin, Louisiana, on Monday, December 30th, Dr. E. L. Drummond.

GIBBONS.—In Kansas City, Missouri, on Monday, December 30th, Dr. R. J. Gibbons, aged fifty-four years.

GIDDINGS.—In Bakersfield, Vermont, on Thursday, January 2d, Dr. W. H. Giddings, aged sixty-seven years.

KEIRLE.—In Baltimore, Maryland, on Sunday, January 5th, Dr. Nathaniel Garland Keirle, Jr., aged thirty-three years.

MATTHEWS.—In Columbus, Ohio, on Tuesday, December 24th, Dr. Reid C. Matthews.

OVERTON.—In Exploit Point, Newfoundland, on Friday, January 3d, Dr. Henry Rutherford Overton, of New York, aged forty years.

TOWN.—In Spencerport, New York, on Thursday, January 2d, Dr. Arba M. Town, aged sixty-eight years.

WETMORE.—In Catskill, New York, on Sunday, January 11th, Dr. Calvin A. Wetmore, aged seventy-six years.

#### THE VALUE OF THE SOCIAL WORKER AND THE VISITING NURSE TO THE DISPENSARY PATIENT.\*

BY LINSLEY R. WILLIAMS, A. M., M. D.,  
New York,

Chief of Clinic, Department of Medicine, Vanderbilt Clinic; Instructor in Medicine, Columbia University; Assistant Attending Physician to the City Hospital.

The population of Greater New York, according to the State census of 1905, was 4,014,000, of which the borough of Manhattan gave 2,122,000, over one half. It seems almost incredible that during the year 1905, 994,315 patients applied for free treatment at dispensaries in greater New York—that is, one fourth of the population willingly affirmed that they were unable to pay for medical treatment. This statement, however, bears qualification. Very few dispensaries are able to maintain an adequate system of records, so that an old patient is always an old patient, but in many dispensaries the system is lax, so that an old patient becomes a new patient when transferred to another department, and often when the dispensary card is lost he is counted as a new patient. It is known to dispensary physicians that many patients rarely continue long at any one dispensary; they become "rounders," drifting from dispensary to dispensary, not sick enough to be admitted to a hospital, and thinking, like the well to do patient, that some new doctor will help him. The large total, then, is far more than the actual number of individual patients.

According to the report of the State Board of Charities, 994,315 patients applied for free treatment in 1905, 869,866 applying for treatment in Manhattan—that is, 87 per cent. The population of Manhattan that year was 50 per cent. of the whole. In other words, Manhattan bore the brunt of the dispensary work. There are ninety-six dispensaries in greater New York, and sixty of them are in Manhattan—that is, with half the population, two thirds of the dispensaries take care of over four fifths of the ambulant sick.

In the year 1906 the numbers had diminished in greater New York 9,000 and in Manhattan 17,000. It does not seem possible that 852,200 of the inhabitants of Manhattan are so poverty stricken that they are unable to pay for medical attendance. The registrar of a dispensary is, by law, also a financial investigator, but as he is usually the entry clerk he has no time to investigate, so that in the last resort

more widely known dispensaries there is practically no investigation made, and medical relief is given without investigation; and in our college clinics the investigation has been winked at in order to increase the number of patients, for the sake of material for teaching purposes. The result has been that the dispensary classes have grown, and now, with their enormous numbers, the physicians are utterly unable to give careful examinations and adequate treatment to the patients.

Do not understand that this applies to all dispensaries, but it does apply to most of the larger dispensaries. The chief difficulty in the dispensary situation in New York, then, is too many patients.

In some large clinics the number of patients has not increased in the last ten years, but the amount of necessary work for each patient has increased with modern methods of treatment, so that with even an increased number of physicians the treatment is unsatisfactory and inadequate. This does not apply, of course, to all our large dispensaries equally, nor does it apply to all departments. It applies mainly to the departments of general medicine, which treat from 25 to 35 per cent. of the total number of patients.

The result of this has been that the physician in a medical department tries to observe a few patients interesting to him and to "get rid of" the others as rapidly as possible. I use the term "get rid of" advisedly, for I know that my personal experience has been that of others, and I do not think that I am less conscientious than the average dispensary physician.

There has been many a long, hot summer afternoon when, with no assistants, I have treated from fifty to eighty-five patients, and my sole purpose on those afternoons was to pacify the patient, give him a prescription, and cursorily examine the new patients, so that I would make no "bad breaks," and send them all on their way rejoicing. Then I would go home, feeling that I had done no good to any patient and harm to some, and, as far as I was concerned, I had gained only physical and mental fatigue. This, surely, has been the experience of many.

Let us turn for a minute to the small dispensary, or to the dispensary where the patients have been divided into small classes.

The physician in charge has been able to take a personal interest in each patient; he has been able to study the influence of home and working conditions on the production of disease, the state of the room, the ventilation, the crowded quarters, the irregular habits of living, the lack of intelligence in

\*Read before the Association of Public Health Agencies at New York, November 1906.

the care of the body and in the preparation of food. He has been able to inquire into the patient's habits and methods of work, the hours of labor, the kind of labor; stop to learn, for example, that "railroad business" may be driving a horse car, that an operator may use his own feet for power or have power provided for him—all of which conditions are factors in the production of disease. Because there were few patients the physician was able to do just what a physician would do for his private well to do patients—find out what should be done for them, and see that they do it. The first is hard enough and the latter more difficult still. He would find out whether his patient needed occupation or change of it, if he needed a change of air, if he needed to be moved from the top floor to the ground floor, or from the basement to the top floor. If he were in need of special hospital treatment or sanatorium treatment, or special treatment for baths, electricity, massage, gymnastics, and so on, and then by a knowledge of where these treatments can be obtained, he has seen that his patient obtains them. He has further seen whether relief is needed, food, rent, clothing, and so on, and he has obtained it through the proper channel.

In other words, this physician was a social worker, and in New York this social work was instituted with the beginning of the tuberculosis clinics.

Fully realizing these facts, Dr. Richard C. Cabot, in Boston, attempted to make the large dispensary do what the small class for tuberculosis had so successfully done. In 1906 Dr. Cabot engaged a trained nurse, who could act as a social worker and who could give the necessary information to patients who needed more than the dispensary physician could give. This work he called social service. To see that the patients followed out this advice volunteers were asked for who could visit these patients subsequently—that is, follow them up and see that the advice was taken. The substance of Dr. Cabot's report was read before the Society of the Alumni of the Presbyterian Hospital in December, 1906. During the discussion it was brought out that at the Vanderbilt Clinic, in New York, plans had already been formulated for such work, and that it would be begun as soon as funds were forthcoming. At the close of the meeting a hospital manager who was present offered to defray all necessary expenses for a year.

The work was begun at the Vanderbilt Clinic in January, a woman physician taking the position of social worker. The need is apparent, yet often on the busiest days, in the desire to get through with the patients, no cases are referred to the social worker.

What does this social worker do? This can be best explained by reading the record of several cases successfully and several unsuccessfully treated.

CASE I.—E. L. Rubin Jew, three years in United States; age, twenty-two years; operator. Referred to Social Service February 11, 1907, for change of occupation.

Patient is suffering from neurasthenia and nervous dyspepsia, and says that the confinement and want of ventilation in the factory where he is employed render her fatigued and nervous. She is a girl of good education, speaking French, German, Spanish, Italian, Turkish, Jargon, English,

and a little Russian. She is, however, unable to write English. Her father was formerly prosperous, owner of a mill in Russia. At present he has no work, and the family are dependent upon the wages of the daughter and the money received from a lodger. Application for employment has been made for this patient at Macy's, Wanamaker's, Singer Machine Company, Long Island College Hospital, Charity Organization Society, Association for Improving the Condition of the Poor, Joint Application Bureau, Ellis Island, Special Employment Bureau, and to the Douglass Phonograph Company. The patient's inability to write English and her lack of experience as saleswoman have made all efforts to secure for her a place with adequate compensation unsuccessful.

CASE II.—J. W., born in United States; single; age, thirty-two years; butcher's helper. Referred to Social Service March 11, 1907.

Patient is exceedingly depressed, morbid, suspicious, and apprehensive. Last August he had a severe epileptiform convulsion, and since that time has been greatly worried in regard to his health. He says that his occupation is unhealthy; he works in a slaughter house and in a stooping position; spends the working day in removing the skin from animals. He takes large amounts of alcohol. He imagines that those about him wish to do him harm. Patient was encouraged and urged to return to the clinic, but he seemed utterly hopeless, said that he was tired of life, and the thought of suicide was constantly in his mind.

The patient was referred to the St. Vincent de Paul Society for Friendly Supervision. But the patient was not found, as he had moved from the address given by him at the clinic.

CASE III.—S. E., born in Russia; Jew; twelve years in the United States; married; age, forty-eight; cutter. Referred to Social Service February 6, 1907, for occupation.

Patient is a case of arrested pulmonary tuberculosis who at the present time suffers from emphysema. He has also an old trachoma that detracts greatly from his personal appearance. Patient is almost without education, as he can neither read nor write. He thinks that he could be a peddler, but does not know how to get a license.

February 8th called at Bureau of Licenses, but found that for some time the Mayor has ceased to issue new licenses.

February 10th patient was referred to Special Employment Bureau. Position was secured for him as assistant at a news stand. Patient remained a part of one day and was discharged because he could not write an account of his sales. Special Employment Bureau then said that they could do nothing more for patient.

February 25th, spoke to United Hebrew Charities about case. They said that patient was lazy and declined to do anything for him.

March 13th, gave patient a letter of introduction to Elevated Railroad Employment Bureau, asking for patient a position as gateman. Patient's want of education excluded him from such work. Gave patient a general letter, stating that he is in need of work, telling him to present it to Yiddish theatres and other places where a man of his nationality might find a position.

Patient has had no success in his quest for employment. He is unable to do heavy work and has no education for other work.

CASE IV.—R. H., Irish; widow; age, twenty-five years; housewife. Referred to Social Service March 14, 1907, for change of air and rest. Patient was referred to the Association for Improving the Condition of the Poor, and the following facts were brought out in the investigation:

Some years ago patient married a West India negro. He died about three years ago, leaving her with a young child. She was not strong and succeeded in having the child admitted to a home, as it was impossible for her to support herself and the baby. Not feeling well enough to work, she remained with a colored woman until she was about to be turned out. At this time a colored man invited her to become his housekeeper. She accepted this place and since that time has lived in very vicious surroundings. She does not profess much affection for her employer, but says that she cannot work. The Association for Improving the Condition of the Poor refused to do anything for the case, and, on a promise of the woman to return to Ireland with her child, one of the Paulist fathers promised to provide the money. Pending the making of the necessary arrange-

ments three different homes were applied to for a temporary shelter. All refused, and finally the Sisters of the Good Shepherd agreed to take her and the patient promised to go. At the last moment she changed her mind suddenly and said that she preferred to return to her former home among the negroes. Argument and appeal only met with the response: "Negroes are as good as any one. I do not feel like working, I do not want to go to the Sisters, I want to go back home."

CASE V.—M. D., born in the United States; stenographer. Referred to Social Service February 2, 1907, for investigation and advice.

Patient was suffering from neurasthenia and gastrop-tosis. She had spent over one year visiting various clinics and physicians. Instruction in hygiene given patient, and, at the request of attending physician, special arrangements were made for her to receive massage for the gastrop-tosis, the price being merely nominal. After taking the treatment for a few times patient failed to appear, either for medical treatment or for massage, although when last seen she was somewhat improved.

CASE VI.—C. B., born in the United States; guard on subway; single; age, twenty-five years. Referred to Social Service February 11, 1907, for change of occupation.

Patient was a case of arrested pulmonary tuberculosis, but losing ground on account of lack of proper air and sunlight. He had repeatedly tried to secure employment on the elevated railroad, but had been unable to do so. A personal letter was given patient to present to one of the assistant superintendents.

April 1st, was given employment as guard on the elevated railroad.

April 20th, patient improving greatly.

CASE VII.—K. G., born in Germany; twenty-four years in United States; domestic; single; age, twenty-six years. Referred to Social Service April 12, 1907, for a place of shelter during pregnancy.

Patient is of a low grade of physical and mental development and utterly unable to plan for herself. Her sister is poor and has a large family and was not in a position to aid patient. After unsuccessful application to three different institutions, patient was admitted on April 3d to the Margaret Strachan Home.

CASE VIII.—W. G., born in United States; wood polisher; married; age, thirty-six years. Referred to Social Service April 12, 1907, for admission to hospital.

Patient was a case of pulmonary tuberculosis and in so weak a condition that immediate hospital care was urgently required. He said that while he saw the necessity of medical care and proper nursing, he was reluctant to leave his wife, whose earnings were too small to support herself and two children. Patient was assured that his family would be cared for, and through telephonic arrangement he was admitted to St. Joseph's Hospital on April 12. His family were visited and the case referred to the Association for Improving the Condition of the Poor.

CASE IX.—E. M., born in United States; schoolboy; age, twelve years. Referred to Social Service February 6, 1907, for investigation as to cause of extreme nervousness.

A visit to the family revealed the following conditions: The household consisted of father, mother, and six children, the patient the oldest and the youngest twins of six months. The family lived in three rooms and the patient shared his bed with two other children. There was in the place great confusion and disorder. Babies crying, children quarreling. The mother weak and ill, food insufficient and of the coarsest description. Patient was allowed to drink strong coffee and beer, and no attention was paid to bathing or to sanitation. Patient was instructed to take a walk daily and to join the gymnastics of the Neighborhood House. A proper diet was ordered, and through the Association for Improving the Condition of the Poor, milk and eggs were given the family for patient.

After a brief confinement in the household care much improved, patient is happier and less nervous, gaining in strength and weight. The babies have been treated in a hospital and the youngest twins have had an opportunity to recuperate.

CASE X.—I. H. Jones, born in the West Indies, nurse, and caught measles in United States; age, forty-seven years. Referred to Social Service.

Patient has erysipelas, and is without means and unable to work. He is restless and discouraged, and says

that he would like to return to his family in the West Indies.

Through the Department for Dependent Adults arrangements were made for deportation, and pending such arrangements patient was admitted to a hospital.

The social worker thus is a bureau of information, who not only gives information to the physician in the dispensary, but also applies that information for the benefit of the patient. The family physician or specialist, with his will to do patient who needs a change of air, a cure at a watering place, or an admission to a tuberculosis sanatorium, ascertains for himself all the particulars in regard to these places and institutions, and is able to intelligently advise his patients where to go. This same physician, with his poor patient in the dispensary, is utterly unable to more than tell his patient to go on as he is doing, and renew his prescription. Of course there are individual exceptions in every dispensary, but what was possible for a few patients, with one or two doctors, is now being made possible for a great many patients.

At the Vanderbilt Clinic it is now possible for any physician working in the dispensary, by means of the social worker, to obtain almost everything that a patient can need. The social worker during the past eight months has been able to obtain suitable employment and change of employment, and has been largely helped by the work of Dr. T. C. Janeway, through the Charity Organization Society Committee for the Employment of the Handicapped. Patients have been admitted to homes for incurables and for convalescents. Patients have been secured special diets, especially for diabetes and for constipation. Instruction has been given to many patients in hygiene, and material relief has been obtained for a large number of patients.

We have also been fortunate enough at the Vanderbilt Clinic to have recently installed a complete apparatus for the application of hydrotherapeutic measures under the direction of Professor Simon Baruch, and are able to give hot baths and hot packs, tonic baths, douches, and so on.

We have also purchased a baking machine for joints; and have recently secured the cooperation of Mr. Jacob Bolin, who, with the pupils in his school of massage and gymnastics, is able to give massage and gymnastic exercises.

In February, 1903, under the direction of Dr. J. A. Miller, classes were begun for the treatment of pulmonary tuberculosis, and a visiting nurse was engaged. This was the beginning of the "follow up" work, and it showed what a strong hold could be maintained upon each individual patient, and how the nurse could encourage and stimulate the patient into carrying out the directions given him.

This work of the visiting nurse amongst the tuberculosis patients has been primarily educational, and the nurse has taught all the detail of the care of the consumptive to the patient and his family, in his own home.

The tuberculosis work, which at first spread over a large area, has been limited to a district north of Fifth street and west of Eighth Avenue. At the present time two nurses are engaged in the tuberculosis work, and each patient in this district is visited at least once a fortnight.

Owing to a very inadequate history system, we have been unable to report on the percentage of tuberculosis cases arrested, but the results have been similar to that obtained at other clinics. An excellent history system has just been inaugurated, and satisfactory reports will soon be able to be made.

In the winter of 1905 a nurse was engaged to do actual nursing in the homes of the poor. It is surprising what a comparatively small number of patients have been referred to the nurse for actual nursing. The visiting nurses at the Presbyterian Hospital receive a larger number of patients of this kind, for convalescent patients from the hospital are referred to them daily. The nurses from the Nurses' Settlement do a large amount of nursing in the home, but from many dispensaries no patients are referred to the Nurses' Settlement, simply because it is more red tape for the doctor, and in the dispensary the nurse must be on the spot to receive the patients.

No part of the outdoor nursing is as valuable as that amongst the children. A nurse was placed in the children's department in the summer of 1906, with most satisfactory results, especially satisfactory in instructing mothers how to care for and feed their babies. The nurse sees the mother at the clinic, and makes an appointment to show her how to prepare the baby's food. The following cases reported by the nurse well illustrate the value of her work:

"A child of five months with indigestion, who had been fed every time she cried. The mother was at the clinic on Tuesday, and an appointment was made for 9 o'clock the next morning, and she was told what was needed to prepare the food. The mother was visited at the appointed hour. There was no milk in the house, the mother saying as an excuse that the husband was out of work. Considerable time was expended in getting together milk and the necessary materials. As the mother could not read, she had to memorize everything that was necessary. Visited the following morning, the child still having indigestion, it was found that the mother had forgotten all the instructions. Reinstructed and visited again on Saturday. Mother had remembered instructions and had followed them out, and the child was doing well."

"The feeding of the babies must be done properly, for with chronic indigestion, which results from improper feeding, the baby quickly succumbs to acute diseases of childhood, and is constantly predisposed to attacks of summer diarrhœa. Education of the mothers, then, is the beginning of success in our work, just as it is in the care of the consumptives."

This nursing work has steadily grown, and is now well organized, with five nurses to inspect all the cases of tuberculosis referred to us in our tuberculosis district, but also to do actual nursing in the homes of the poor, and to instruct mothers in care and feeding of infants and children. For several years patients were treated who lived anywhere in the city, the nurses even going to the Bronx and to Brooklyn, but the extent of the work has been gradually curtailed, owing to the establishment of special tuberculosis dispensaries in those boroughs, so that, in 1905, the nursing work was confined to Manhattan only.

During that year a special effort was made to curtail the number of visits upon each tuberculosis patient. For example: Our nurse would visit a new patient, and the case would be reported to the Department of Health. They would send an inspector,

who would subsequently send a nurse from the Department of Health. The case would be referred to the Charity Organization Society, which would investigate, and find that the patient had previously been assisted by the Association for Improving the Condition of the Poor. The Association for Improving the Condition of the Poor would send their visitor to investigate, and by this time the patient wished that he had never seen a nurse, or doctor, or social worker. By means of an agreement with the Department of Health, no inspector or nurse is now sent unless upon our written request, and all patients are visited until they have moved or died, when the rooms of the patient are fumigated. In other words, we keep under observation every case of tuberculosis in our own tuberculosis district that has been referred to us. To eliminate the number of unnecessary visits made by representatives of the charitable societies, I wrote to the New York Association for Improving the Condition of the Poor, asking if our senior nurse could not be made a volunteer visitor of that society, and to directly investigate her own patients and to directly give relief under their supervision. This the association agreed to do, and this agreement has been carried out for nearly two years with marked success, and material relief has been given not only to the tuberculosis patients, but also to the families of other sick patients who were coming to the clinic for treatment, so that now, instead of having four, five, or six visits from different people, the patient receives a visit from but one nurse. This increases his confidence, and enables us to treat the patient in a more thorough and satisfactory way.

For three years I had the privilege of being examining physician for the Association for Improving the Condition of the Poor, and was very much interested in the examination of the mothers and children who constituted their fresh air parties. As result of this work cooperation with fresh air work was easy, and we were able during the summers of 1904, 1905, 1906, and 1907 to send away for fresh air vacations, by means of the Association for Improving the Condition of the Poor and other agencies, a total of 1,565, as shown in the accompanying table:

*Fresh Air Outings to Members of Families.*

	Day's outings.	Week or more.
In 1904.....	21	7
In 1905.....	310	23
In 1906.....	1,073	82
In 1907.....	523	152

These were almost all mothers and children.

During July, August, and part of September, 1907, the New York Association for Improving the Condition of the Poor maintained a day camp for babies at Junior Sea Breeze at the foot of East Sixty-fourth street. This institution was an educational one, to teach mothers how to care for infants and children. A staff of from ten to twenty-three visiting nurses was maintained from July 15th until September.

Instead of waiting for patients to come, the nurses were sent out into the homes of the rich and poor alike, offering instruction in the care of babies and children.

The Board of Health put the inspectors of the

summer corps in the Nineteenth ward as soon as the garbage strike was over, and they visited families according to the plan of the department's summer corps work. The visits of the Junior Sea Breeze nurses were also confined to the Nineteenth ward. The Nineteenth ward is bounded on the south by the south side of Thirty-ninth street, on the east by the East River, on the north by the south side of Eighty-sixth street, and on the west by the east side of Sixth avenue and Central Park.

The nurses visited every dwelling in this ward, interviewing all who would be interviewed, recommending hospitals, dispensaries, and doctors, parks, piers, and shady streets, fresh air, cleanliness, and careful feeding, leaving printed circulars on the care and feeding of children.

Special cards were filled out for all the sick children, and frequent revisits were made.

The care of milk was insisted upon, and instructions given as to its care, as well as the care of the baby, its clothing, feeding, and so on. Every effort was made not to help the mother and her family, but to make the mother help herself.

Table of Visits.

Number of tenements visited, .....	17,261;
" " miscellaneous dwellings visited, .....	8,495;
" " families (visits), .....	116,601;
" " children under two years, .....	34,453;
" " revisits, .....	2,342;
" " sick treated, .....	1,062;
" " sick placed in hospital or dispensary, ..	90;
" " sick referred to hospital or dispensary, ..	781;
" " individual families seen, .....	101,208.
Instruction given:	
In bathing, .....	20,837;
In feeding, .....	21,218;
In cooking, .....	14,350;
In clothing, .....	19,716;
In fresh air, .....	35,738;
In nursing sick babies, .....	2,877;
In general care, .....	35,697.

With this enormous number of visits it may seem that the work was casual and valueless. The work of the individual nurse varied considerably, and the results looked for, while not conclusive, proved strikingly suggestive.

It was hoped that there would be a reduction of the infantile mortality in this ward. The Department of Health gave the Association for Improving the Condition of the Poor the privilege of going over the records at the department where Dr. W. H. Guilfoyle, registrar of records, gave much assistance to a skilled worker. The following table shows the diminution in mortality:

Manhattan and Bronx, July 1 to September 14, 1907, as compared with preceding year:

	1906	1907	%
Total deaths, all causes, .....	9,746	9,079	— 6.83
Total deaths from diarrheal diseases, .....	2,050	2,084	+ .16
Total deaths from diarrheal diseases, ..			
under five, .....	1,943	1,980	+ 1.90

Nineteenth Ward, July 1 to September 14, 1907, as compared with preceding year:

	1906	1907	%
Total deaths, all causes, .....	1,022	904	— 11.8
Total deaths from diarrheal diseases, .....	274	236	— 13.8
Total deaths from diarrheal diseases, ..			
two years and under, .....	253	221	— 12.6
Total deaths from diarrheal diseases, ..			
under five, .....	254	222	— 12.6

It cannot be said that this visiting nursing was the cause of this reduction, but it is certainly suggestive.

There were also three nurses at work, visiting mothers living in tenement houses, before confinement, teaching them how to care for themselves before and after confinement, and visiting them afterward and teaching them how to care for the baby. This was done where the mother could not afford a doctor except for the actual confinement, or where a midwife was in attendance. In no case did the nurses deliver any of these patients.

Opportunities for visiting nursing in New York are enormous, especially on account of their educational value and their value in the field of preventive medicine. Cooperation is necessary, and endeavors are being made to bring the various nursing associations closer together. The cooperation between the tuberculosis clinics has been a splendid object lesson which will bear good fruit.

Arrangements have recently been made with the Nurses' Settlement so that patients from the Vanderbilt Clinic who live south of Fourteenth street and east of Broadway who are in need of nursing may be referred to the Nurses' Settlement. Cases referred to the settlement, living north of Seventieth street and west of Eighth avenue may be referred to the Department of Visiting Nursing at the Vanderbilt Clinic when nurses of the Nurses' Settlement are unable to care for them. Patients applying for treatment at the Vanderbilt Clinic, living north of Fifty-ninth street, south of Ninety-sixth street, and east of the Park, who are in need of nursing, will be referred to the Presbyterian Hospital Visiting Nursing Association. And if patients living in the Vanderbilt Clinic Tuberculosis District north of Fiftieth street and west of Eighth avenue should apply to the Presbyterian Hospital Dispensary will be referred to the Vanderbilt Clinic Department of Visiting Nursing. At the Roosevelt Hospital Surgical Out Patient Department a visiting nurse has recently begun work, and it is hoped that her work will ultimately be confined to the same area covered by the Vanderbilt Clinic, and that both this nurse and the nurses from the Vanderbilt Clinic will work more closely together.

A thorough description of all the agencies in this city maintaining visiting nurses and social workers has recently been made by Dr. S. S. Goldwater, of Mt. Sinai Hospital, in an article entitled *Dispensary Ideals*. The visiting nurse and the social worker will not reach their highest state of efficiency until some of these ideals are reached. Such ideals as the districting of the city for dispensaries, the districting of the city for visiting nursing consist in:

The doctrine of small numbers.

No medical relief without previous application, except in cases of emergency, and more frequent and thorough financial investigation.

The accomplishment of these ideals will result in smaller classes at the more popular, large, and over-worked dispensaries, a more equal division of labor, less imposition by patients who can afford to pay, and infinitely better care of the outdoor sick poor.

830 MADISON AVENUE

## CHOLELITHIASIS.

*A Study of Twenty-five Operative Cases.\**

BY CHARLES H. PECK, M. D.,  
New York,

Attending Surgeon to the French Hospital; Junior Attending Surgeon to Roosevelt Hospital.

In considering the question of diagnosis and especially the indications for treatment, each clinical group presents certain characteristics and problems of its own.

Certain cases of undoubted cholelithiasis still belong in the domain of internal medicine, e. g., the cases of biliary colic with the passage of one or more stones, characterized by paroxysmal pain, vomiting, and transient icterus, with immediate relief of all symptoms after the passage of the stone.

Recurrent attacks of pain in the upper abdomen, without fever, jaundice, presence of a mass or rigidity, and in which tenderness is moderate, slight, or absent, are typical of another group of cases which may be said to occupy the border line between medicine and surgery. Many are treated for years by the general practitioner, bearing the exacerbations of pain as best they may, with varying disability and interference with the routine duties of life, according to the frequency, severity, and duration of the attacks. Some become morphine habitues, as in Case VI of my series. That the operation is not entirely free from danger even in this simplest of gallbladder conditions is well known, and is illustrated by Case III with the patient who died of cerebral embolism four days after operation, and this fact deters many physicians from advising and many patients from consenting to operation in a condition which may exist for years without actual menace to life. Such cases usually have stones in the gallbladder too large to pass the cystic duct, which from time to time become temporarily lodged in a dilated ampulla or at the entrance to the duct, which is often strictured, causing painful spasm or temporary obstruction.

Complete obstruction of the cystic duct, with the development of hydrops, empyema, or gangrene of the gallbladder, may occur, but is often escaped for years.

The age, the general condition of the patient, the frequency and severity of the attacks of pain, the amount of disability and the effect on the general health, together with the necessity for the use of opiates, are all factors which must be carefully weighed in the balance in determining as to whether or not an operation should be advised.

Of the series presented six were of this type (Cases I to VI), and illustrate some of the indications for operative treatment, the attacks having extended over periods varying from three months to twenty years. Case II, a hard working cobbler with a large family to support, bore his repeated attacks of pain for about three months, when the suffering and especially the interference with his occupation rendered him only too glad to consent to an operation, since which he has been perfectly well. His history in brief was as follows:

CASE II.—Patient was forty years of age and had always been well up to about three months before operation.

Since that time he had suffered from frequent attacks of severe pain in the region of the gallbladder. No jaundice, chills, nor fever, but pain had been so frequent and severe as to interfere seriously with his work, though not ill in bed. Examination was negative, except for moderate tenderness on deep pressure over gallbladder. Cholecystectomy was performed August 18, 1906. The gallbladder was moderately thickened and the ampulla dilated. It contained a single ovoid stone of a peculiar white crystalline appearance, and a rough mulberrylike surface. The cystic duct was patent. The patient made an uneventful recovery, and has remained entirely free from symptoms ever since.

Many such cases are treated for gastric troubles for considerable periods of time, as illustrated by Cases I, III, and IV, all three having undergone prolonged medical treatment, including gastric lavage, under the impression that the pain was of gastric origin.

CASE III.—A woman, forty-five years of age, had had repeated attacks of pain in gallbladder region for more than two years, without jaundice, chills, or fever. The attacks had been more frequent and severe for the six months prior to operation, requiring morphine hypodermatically for their relief, but she felt perfectly well between the attacks. Gastric lavage was employed for a prolonged period without benefit, a diagnosis of gastritis having been made. Recently the intervals between the attacks had varied from a few hours to two or three days, and she had become very nervous and run down. Examination was negative, except for tenderness on deep pressure over the gallbladder. Cholecystectomy was performed on November 8, 1906. The gallbladder was found to be thickened and distended with grumous bile stained mucus; the cystic duct was rigid and its orifice minute. There was a single rounded, nonfaceted stone of moderate size, and two fragments which appeared to have been flaked off from a larger stone. The patient bore the operation, which lasted fifty minutes, well; had a moderate reaction temperature and little vomiting. Bowels moved freely on the second and third days in response to calomel and enemata. The wound was dressed on the third day; there was no distension; no apparent wound infection; the drain was not disturbed. Temperature and pulse were practically normal, and patient seemed in excellent condition. That night (fourth day after operation), while asleep, her breathing suddenly became stertorous, she frothed at the mouth, and became completely comatose. The pupils were contracted and equal. The coma continued, and she died within twelve hours, four days after the operation, probably from cerebral embolism, though no autopsy could be obtained.

In Case IV both gastric and gallbladder lesions had undoubtedly been present, the extensive perigastric adhesions indicating the previous existence of gastric ulcer.

CASE IV.—The patient, a woman thirty years of age, had suffered from attacks of pain in the upper abdomen for about three years. Had had occasional vomiting, but no jaundice, chills, or fever. She had received prolonged treatment for gastric disorders, including lavage, at a dispensary. Examination was negative, except for slight tenderness on deep pressure over gallbladder. Operation performed at Roosevelt Hospital on June 21, 1907. The upper abdomen was filled with a mass of weblike adhesions. The stomach, colon, liver, and gallbladder were adherent to each other, and to the anterior parietes. The gallbladder was removed; it contained three good sized stones; the cystic duct was not occluded. No stones found in hepatic or common ducts. Adhesions binding stomach to anterior abdominal wall were separated, several bands being ligated and divided. The anterior wall of the stomach showed old cicatrices, evidently the sequelae of ulceration. The patient made an uneventful recovery and left the hospital well on July 10, 1907, nineteen days after operation.

Patients suffering from this type of cholelithiasis seldom come to the surgeon until medical means have been thoroughly tried over a period of months or years, the mere lapse of time without improvement being often sufficient to determine the neces-

\* From the report of the Nurses of the City (Charity) Hospital, New York.

sity for operation. Case VI, the widow of a physician, finally sought operation after having had attacks of pain for more than twenty years, in the hope of ridding herself of the morphine habit. Her history was as follows:

CASE VI.—She was fifty-eight years of age, and had had an illness lasting two years, thirty years ago, characterized by severe attacks of epigastric pain and the passage of gallstones. Had had repeated attacks of pain in the region of the gallbladder for about twenty years, without jaundice, chills, or fever, resulting in the development of the morphine habit. The patient was extremely stout, and this, in connection with her age, morphine habit, and poor general condition, caused much hesitation and careful study of the case in all its aspects before the decision to operate was finally reached. Operation was performed on August 19, 1904. The gallbladder was shrunken to such an extent that it was hardly recognizable. It was surrounded by adhesions which had drawn the pylorus over to the right. Cholecystectomy was performed, adhesions were freed, and the ducts explored; no stone was found. Recovery was slow, but finally complete, with relief of pain, and cure (for the time under observation at least, up to October 26, 1906) of the morphine habit. A large ventral hernia developed in the wound, necessitating operation on March 16, 1905.

To summarize the six cases of this type, in three, single nonfaceted stones were found; one (Case IV) had three good sized calculi, and extensive perigastric adhesions; one (Case V) had twenty or more small, jet black, mulberry like stones composed of bile pigment, of the variety frequently found at autopsy but which rarely give symptoms, and Case VI, the history of which included attacks of colic followed by the passage of calculi, presented a diminutive, shrunken gallbladder, with adhesions to the pylorus, but no stone.

#### *Cholelithiasis with Acute or Chronic Cholecystitis or Empyema of the Gallbladder.*

There were nine cases of this type in the series, and one, Case XII, of acute cholecystitis without stone.

The symptoms, in addition to pain and vomiting in the attacks, were fever, sometimes chills, well marked localized tenderness and rigidity, and greater disability, the patients always being ill enough to remain in bed. Jaundice, usually very slight had occurred at some time during the illness in six of the ten cases. Attacks of acute inflammation of the gallbladder are always accompanied by more or less obstruction of the cystic duct. Resolution, with reestablishment of the patency of the duct and natural drainage, may occur, but is seldom complete. The gallbladder wall remains somewhat thickened and rigid, the duct narrowed, and sooner or later the symptoms recur. That patients may pass through a number of such attacks, however, with comparatively long intervals of freedom from symptoms, is a well known clinical fact. Case IX gave such a history, having had an interval of fifteen years free from symptoms, followed by the sudden onset of acute suppuration.

CASE IX.—The patient was a woman fifty-nine years of age, who began to have attacks of colicky pain and vomiting when about thirty years of age. About fifteen years ago she had a severe illness, with pain, tenderness, fever, and the passage of gallstones, and was ill in bed for about six months, and not well for more than a year. Since that time, except for occasional pain and indigestion, there was no return of the trouble until the onset of the present attack two days ago, with exacerbating pain, vomiting,

fever, and prostration; no jaundice. There was extreme tenderness over the gallbladder and an ovoid mass was palpated. Temperature on admission, 103° F. Cholecystostomy was performed; about six ounces of mucopus and fifty-eight white, faceted stones were removed. Reaction temperature reached 105° F., but in a few days fell to normal. Slight pocketing of pus in Morison's pouch at end of second week. Convalescence was slow, but finally complete. Superficial abscess in wound opened and drained about three months later.

Instead of resolving, however, many such cases terminate in perforation or gangrene of the gallbladder. Perforation may occur into the colon or duodenum, with spontaneous subsidence of the symptoms. It may take place on the liver surface, forming a localized abscess, or into the peritoneal cavity, causing local or general peritonitis. Acute cholecystitis should always be regarded with suspicion, and early operation is the safest rule. A damaged gallbladder more or less buried in adhesions, a strictured cystic duct and almost certain recurrence of the attack is the most favorable outcome one may expect, while perforation or gangrene are possibilities to be considered in every beginning case.

In close relation to the cases of acute cholecystitis with partial or temporary obstruction of the cystic duct are those in which such obstruction is complete and empyema of the gallbladder results, the course depending largely on the virulence of the infection and the relative resistance of the patient. My most recent case, XVI, illustrates an extremely sluggish type, and the enormous distension of the gallbladder which may occur without rupture.

CASE XVI.—The patient, a woman thirty-four years of age, was sent to Roosevelt Hospital for treatment of a large abdominal tumor which was thought to be an ovarian cyst. The mass was as large as a child's head and occupied the right side of the abdomen, its greatest prominence being about opposite the umbilicus. It was spheroidal in shape, not movable, nor sensitive; no fluctuation could be made out. There was no fever, and the leucocyte count was normal. There was a history of an attack of abdominal pain about three years ago, without fever, jaundice, or development of a mass; a similar attack eight months ago, after which a lump was felt which never entirely disappeared, and a third attack about six weeks ago, after which the mass rapidly enlarged until it reached its present size. Some pain persisted, but there was no fever, chills, nor sweating, and no jaundice, the chief complaint being the presence of the tumor. The clinical picture suggested hydronephrosis, but catheterization of the right ureter drew normal urine. Operation was performed at Roosevelt Hospital on September 20, 1907. The right kidney was exposed by an oblique incision, found normal, and the wound at once closed. The manipulation of the patient in the kidney position dislodged the tumor so that it became more movable and shifted toward the median line. The patient was turned on her back and laparotomy performed. The tumor was an enormous gallbladder, surrounded by dense adhesions. After partially freeing it from adhesions it was tapped with a large trocar and canula and about three pints of thick, greenish pus evacuated. It was then gradually freed from surrounding adhesions and from the liver and removed. After cutting away tags of liver tissue the large, raw surface on the under surface of liver was partially closed by a continuous suture of heavy catgut. Two large cigarette drains were inserted, and the wound closed in the usual manner. The gallbladder walls were greatly thickened, nearly ulcerated through along the right border of its liver attachment, but not necrotic elsewhere. It contained one small non-faceted stone; the cystic duct was occluded. The patient's condition was critical for about forty-eight hours, after which improvement was rapid. There was a profuse discharge of gelatinous material, probably necrotic liver substance, from the drainage tubes. The patient recovered

healed promptly, and convalescence has been uninterrupted.

I have reported this case in detail because of its unusual interest in respect to the size of the gallbladder, the absence of the usual symptoms and signs of suppuration, the extremely sluggish course, and the failure of any of the dozen or more surgeons who examined the case to even suspect that the tumor was of gallbladder origin.

In contrast to this, Case XV presented the typical symptoms and signs of acute empyema of the gallbladder, i. e., localized pain and tenderness, tumor, fever, elevation of pulse, leucocytosis, and absence of jaundice, the symptoms having steadily increased from the onset to the time of operation. The gallbladder was distended with mucus and contained many stones. The cystic duct was occluded and surrounding adhesions were numerous and dense. Cholecystectomy was followed by a prompt and uneventful recovery.

CASE XII.—Acute cholecystitis without stone was a rather unusual one occurring in a young girl seventeen years of age, who gave no history of typhoid fever or any other previous acute illness. The gallbladder was inflamed, thickened, and contained mucus; the cystic duct was so strictured that cholecystostomy, which was first performed, had to be followed by cholecystectomy fifteen days later on account of recurrence of gallbladder distention as soon as the drainage opening closed.

#### *Cholelithiasis with Acute Gangrene of the Gallbladder.*

It is only a step from empyema to acute gangrene of the gallbladder, partial or complete, with ultimate rupture and local abscess, as in Case XVII, or diffuse peritonitis and fatal sepsis, as in Case XX. Complete occlusion of the cystic duct is followed by a distention of the gallbladder with the mucus secreted by its mucous membrane. Without exit, the tension in certain cases becomes so great that the blood supply is cut off and gangrene results, just as it does in the overdilated appendix, from purely mechanical causes. In other cases it may be due directly to the virulence of the infecting organism, or lowered resistance, but it is my belief that it is more often due to the actual occlusion of the nutrient vessels from intracystic tension. Once perforation occurs and the contents of the gallbladder escape into the peritoneal cavity, a dangerous and often fatal peritonitis results. Case XX admitted in such an advanced stage of peritonitis that the exciting cause could not be determined, illustrates the neglected case, allowed to take its own course until past hope of relief. Case XIX is typical of the condition operated upon just before perforation had occurred. An area the size of a silver quarter near the fundus was completely gangrenous and in a few hours would surely have ruptured, pouring the contents of the gallbladder into the peritoneal cavity. This case also illustrates the danger signs in acute cholecystitis, i. e., at the time of operation, sixty hours after the onset of the attack, the temperature and pulse were steadily rising and the tenderness and rigidity were becoming diffused over a wider area. Any attack of acute cholecystitis in which at the end of forty-eight hours there is no abatement of the tenderness, or of the elevation of temperature or pulse, should be

regarded with suspicion. Diminution of the pain may be an unfavorable symptom, indicating perforation and relief of tension. In such cases, however, the tenderness and rigidity show no abatement.

There were four cases of acute gangrene of the gallbladder in my series, with one death; one had perforated on the liver aspect and the process was localized to the immediate region of the gallbladder. Her history was as follows:

CASE XVII.—A Swedish woman, twenty-nine years of age, had had numerous attacks of pain in the region of the gallbladder during the past five days, without jaundice or fever. Present attack began five days ago with severe pain, tenderness over the region of gallbladder, and fever, all symptoms having increased steadily since onset. On admission to Roosevelt Hospital temperature was 101.8° F.; leucocytes 16,000. Operation was performed on June 16, 1905. The gallbladder was found buried in a mass of adhesions, gangrenous and perforated on the liver aspect; secondary abscesses among adhesions to the inner side. It contained pus, eighteen stones, and was completely gangrenous, except for a portion of its peritoneal coat. Cholecystectomy was performed with difficulty on account of the great friability of the tissues. Febrile reaction was sharp after the operation, the temperature reaching 104.4° F., but convalescence was satisfactory. Patient was allowed out of bed on the nineteenth day and left the hospital well on July 8, 1905, twenty-two days after operation.

Two patients were operated upon before perforation had occurred, one, Case XIX, being fairly typical of the condition prior to perforation.

CASE XIX.—A woman, forty years of age, had had attacks of gallstone colic without jaundice twelve years ago, with occasional pain and discomfort in region of gallbladder from time to time ever since. Onset of severe pain and tenderness over gallbladder about sixty hours before operation; steady increase of symptoms, with rise of temperature to 103° F., pulse to 120. Diffusion of tenderness and rigidity in right upper quadrant; some abdominal distension. Very faint icterus of conjunctivæ. Operation July 31, 1906, cholecystectomy performed. The gallbladder was tensely distended with mucus, and contained thirteen stones. The inner coats were gangrenous throughout, and at the fundus the gangrene had extended to all the coats, and rupture was imminent. The infection had extended to the surrounding peritonæum, free turbid serum escaping on opening the peritonæum, and recent lymph and adhesions filled the entire region. The usual drainage and wound closure were adapted. Convalescence was uneventful, except for the development of an abscess at the lower angle of the wound on the fifth day. Symptoms of sepsis and peritonitis rapidly subsided, and by the end of the third week wound was healed and the patient up and about. This case was on the verge of rupture into the peritoneal cavity, and twenty-four hours later would have undoubtedly had fatal peritonitis.

The fourth case of acute gangrene had ruptured some time prior to operation and had a generalized septic peritonitis at the time of his admission to the hospital. Delay in operating until perforation has occurred is almost sure to be followed by a fatal result.

CASE XX.—The patient, a man thirty-six years of age, was brought to Roosevelt Hospital in the ambulance on August 14, 1906, suffering from symptoms of acute general peritonitis. There was marked distension; general tenderness and rigidity; small, thready pulse. Temperature 101° F., pulse 116, leucocytes 28,500. No history was obtained by the house staff, except that illness had lasted three or four days. Appendicitis was suspected, and an incision in the iliac fossa made. Abdomen was full of seropurulent fluid, but the appendix was not diseased. It was removed and a soft catheter inserted in stump, allowing quantities of gas and fecal matter to escape to relieve distention; stump then inverted with pursestring suture. Palpation revealed a diseased gallbladder and a second in-

cision was made. The gallbladder was completely gangrenous, contained three large and many small stones. It was excised in the usual way, area cleansed, and cigarette drains placed down to stump. Abdomen thoroughly flushed with saline solution through Blake tube before closing. Purulent fluid washed from pelvis and all parts of abdomen. Patient reacted surprisingly well and for about twenty-four hours recovery was hoped for. Signs of peritonitis then increased, and he died at end of forty-eight hours.

#### *Calculi in the Common Bile Duct.*

Movable stone in the common duct presents quite a different picture, characterized by pain varying in severity, duration, and frequency of attacks; jaundice, which, as a rule, is moderate in degree, intermittent, but never entirely disappears; ague like attacks of chills, fever, and sweating; and absence of a tumor. The course is subacute, or chronic, as the obstruction is of a ball valve character and intermittent, the common duct becoming dilated and thickened as the stone increases in size, so that at the time of operation it will often admit the index finger. Case XXI presented a typical picture of this condition.

CASE XXI.—The patient, a man fifty years of age, had been ill for about three years with intermittent pain in the upper abdomen, chills, fever, sweating, slight icterus, and loss of flesh and strength. The attacks occurred frequently but irregularly, the intervals between attacks varying from a day or two to a week. The chills were often severe, lasting twenty or thirty minutes. There was increased resistance and tenderness over the gallbladder, but no tumor. He was operated upon March 30, 1904, at the French Hospital. The gallbladder was shrunken and buried in adhesions. A perforation on its under surface had been sealed by adhesions to the transverse colon. Cholecystectomy was performed, and the greatly dilated common duct laid freely open by incision through the stump of the cystic duct. Two movable ball valve stones were removed, and the duct explored with the index finger and probes. A catheter was passed into the hepatic duct and secured, and the remainder of the incision in the duct closed with fine chromic gut sutures. Bile drained freely, through the tube for three days, when it was removed. All bile leakage ceased on the twenty-second day, the wound healed kindly, and he left the hospital well on May 3d, thirty-five days after the operation. He reported in October, 1906, two and a half years after his operation, that he had remained perfectly well, and had gained about forty pounds in weight.

Such cases should invariably be operated on as soon as the diagnosis is made, as septic cholangitis is sooner or later sure to occur. The four cases of this type in the series all recovered promptly after operation.

#### *Primary Carcinoma of the Gallbladder.*

The one case of this type in the series was associated with acute empyema of the gallbladder, which also contained two large stones. The growth was confined to the region of the fundus, did not involve the liver, and while very large was not exceptionally difficult to remove by the usual cholecystectomy. The patient made a good operative recovery and left the hospital apparently well twenty-three days after the operation. Some months later friends reported at the hospital that she was ill with symptoms which probably meant recurrence in the liver.

Cases of primary carcinoma of the gallbladder amenable to surgical treatment must be extremely rare, and recurrence in the liver is almost certain to follow within a short time. The case presented, in which life was prolonged for a few months in

comparative comfort, is the most favorable one that has come under my observation.

#### *Treatment.*

When operation has been determined upon, the character of the procedure must, as a rule, be decided upon after the abdomen is opened, and except in cases of stone in the common duct, resolves itself into a choice between cholecystectomy or drainage of the gallbladder after removal of stones, and cholecystectomy or its complete excision. Ideal cholecystotomy, i. e., removal of stones, suture of the gallbladder, and closure without drainage, is unsafe, and has been practically abandoned. Of my twenty-five cases, primary cholecystectomy was performed in twenty-one, with two deaths—Case III, where the patient died of cerebral embolism on the fourth day after operation, and Case XX, with death from general peritonitis, due to acute gangrene of the gallbladder and present at the time of operation. Secondary cholecystectomy was performed in Case XI, the primary cholecystotomy having been performed by another surgeon two years before and followed by persistent suppurative in the gallbladder and adjacent regions. In the remaining three cases (IX, X, and XII) in which I performed cholecystotomy, one, Case IX, made a good recovery after rather prolonged discharge from the fistula, but in the other two I was obliged to perform secondary cholecystectomy a few weeks after the cholecystotomy, on account of occlusion of the cystic duct, and recurring distension of the gallbladder as soon as the fistula healed.

In the series of twenty-five cases, therefore, I am able to report only one successful cholecystotomy, while twenty-two cases of cholecystectomy resulted in recovery. Undoubtedly other cases of the series might have been successfully treated by cholecystotomy, but in the majority of the cases the gallbladder or cystic duct were so damaged that cholecystectomy seemed the preferable procedure. That cholecystectomy is attended by somewhat greater immediate operative mortality is probably true, but if the condition present seems likely to demand removal of the gallbladder ultimately to obtain a cure, it is my belief that usually the risk will be less if the cholecystectomy is made the primary procedure. Secondary cholecystectomy has seemed to me an infinitely more difficult and dangerous operation.

I do not question, however, the value and efficiency of the simpler operation in certain cases of the type of my first group, and also in some of the cases of acute cholecystitis, without distinct stricture or occlusion of the cystic duct.

Cases of stone in the common duct require, in addition to the removal of the shrunken gallbladder, incision into the common duct, removal of stones and thorough exploration of common and hepatic ducts to be sure that none are left behind. Hepatic drainage by means of a tube passed into the hepatic duct, around which the incision into the common duct is sutured, should be employed as a rule. Such a tube is removed in from three to seven days, the discharge of bile usually ceasing spontaneously at about the end of the third week.

TABLE OF CASES

No.	Date of operation	Age	Sex	Operation	Result	History	Description of cysts	Remarks
I	June 19, 1926	51	R	Cholecystectomy	Recovery	Repeated attacks of pain for two or three years; prolonged treatment for gallstones. No stones, cysts, or concretions.	Single stone, 2.5 cm. in diameter, gallbladder thickened, cystic duct dilated and strictured.	Uneventful recovery with complete relief of symptoms.
II	June 18, 1926	41	F	Cholecystectomy	Recovery	Repeated attacks of pain for three months. Unable to tolerate fatty food.	Single stone, rough, mulberry like, size 1.5 cm. Gallbladder moderately thickened, cystic duct patent.	Unsuccessful recovery. In period between when sent to hospital after operation.
III	Nov. 15, 1926	38	M	Cholecystectomy and cholecystostomy	Death in hospital	Severe attacks of pain for two years. Prolonged treatment by gastric lavage. No mulberry, chills, or fever.	Single stone of moderate size, two fragments when taken out and gallbladder and cystic duct strictured and thickened.	Unsuccessful recovery. In period between when sent to hospital after operation.
IV	Nov. 15, 1926	41	F	Cholecystectomy	Recovery	Repeated attacks of pain, with occasional vomiting, and times when prolonged treatment by gastric lavage.	Three good sized calculi. A mass of white adhesions filling upper half of gallbladder and extending into cystic duct. Anterior stomach wall.	Unsuccessful recovery. Patient had probably had gastric ulcer.
V	Nov. 15, 1926	41	F	Cholecystectomy	Recovery	Calculus came twice, weeks ago. Repeated attacks for past eight years. Pain every day for the weeks. No chills, chills, or fever.	Few my black mulberry like stones, gallbladder distended, thickened, cystic duct strictured.	Unsuccessful recovery.
VI	Nov. 15, 1926	41	F	Cholecystectomy	Recovery	Two years' illness, with passage of gall stones. Repeated attacks of pain without vomiting, chills, or fever for fifteen years. Pain habit for several years.	Repeated, gallbladder distended and dilated, adhesions drawing as far as to the neck. No calculi.	Recovery, slow but complete, and patient returned to work. Gallstones, chills, and fever, no gastric ulcer.
VII	Nov. 15, 1926	41	F	Cholecystectomy	Recovery	Adhesions in region of gallbladder in 1924, and in 1925, with chills, and other attack five weeks ago.	Gallbladder thickened and contracted, about two good sized calculi.	Unsuccessful recovery.
VIII	Nov. 15, 1926	41	F	Cholecystectomy	Recovery	Attacks of gallstone colic with vomiting and passage of calculi for several years.	Gallbladder thickened and shrunken around lower extremity.	Unsuccessful recovery.
IX	Nov. 15, 1926	41	F	Cholecystectomy	Recovery	Severe illness, fifteen years ago with chills, fever, and vomiting. Gallstone habit for many years at that time. First attack of gallstone colic when thirty years of age. Acute onset forty-eight hours before operation. Brought to hospital in automobile with Exploratory, found stones and cholecystostomy under gastric lavage. Admitted with acute gallbladder inflammation. Cholecystectomy July 1926.	About 1 cm. of mucous and fifty small stones removed from gallbladder.	Recovery, slow but complete. Six months later, patient returned to work three months later. No gastric ulcer.
X	Nov. 15, 1926	41	F	Cholecystectomy and cholecystostomy	Recovery	Cholecystectomy performed five years ago, by another surgeon. Repeated adhesions formation with spontaneous rupture about every two months ever since.	Gallbladder contained thick pus and about fifteen calculi, secondary abscesses in surrounding adhesions. Operation very difficult.	Recovery, slow, from cholecystostomy and left basal cholecystectomy. Reoperation after four months with removal of adhesions from gallbladder and cholecystostomy.
XI	Nov. 15, 1926	41	F	Cholecystectomy and cholecystostomy	Recovery	Three attacks of pain, with fever and pain in the back week preceding operation. No history of attack of other illness.	Gallbladder distended, contained mucous pus, no calculi. Nontoxic complex, cholecystitis, that found at cholecystostomy.	Unsuccessful recovery, followed by cholecystectomy, but not returned to work. In 1926, cholecystectomy performed August 1926.
XII	Nov. 15, 1926	41	F	Cholecystectomy and cholecystostomy	Recovery	First attack of pain, fever, and pain in the back week preceding operation. No history of attack of other illness.	Gallbladder distended about twenty stones, and contained about twenty stones, that of which were lodged in cystic duct.	Unsuccessful recovery.
XIII	Nov. 15, 1926	41	F	Cholecystectomy and cholecystostomy	Recovery	No symptoms until onset of present attack, five days before operation. Slightly increasing pain, tenderness, fever. No jaundice. Mass present.	Gallbladder greatly thickened, tonsil distended with mucopus, tonsil distended with mucopus. Complete stricture of cystic duct.	Unsuccessful recovery.

TABLE OF CASES. *Continued.*

NO.	DATE OF OPERATION	AGE	SEX	LOCALITY	OPERATION	RESULT	HISTORY	DESCRIPTION OF LESION	REMARKS
100	September 1, 1907; General Hospital, St. Louis	37	F	Mo.	Cholecystectomy.	Recovery.	Attacks of pain and vomiting without jaundice for two years. Sudden onsets of inflammatory symptoms three days before operation. Patient had gained weight and about six weeks pregnant. Very large, fat woman.	Gallbladder, lacerated in dense adhesions, contained purulent material. Cystic duct occluded.	Recovery.
101	September 26, 1907; General Hospital, St. Louis	37	F	Mo.	Cholecystectomy.	Recovery.	Chief symptom the presence of a large mass, which was first noticed eight months ago and had increased greatly in size. Attacks of jaundice taken for an ovarian cyst.	Gallbladder enormously distended; contained three pints of pus; one stone visible in the duct. Many adhesions.	Recovery slow but complete.
102	June 16, 1905; General Hospital, St. Louis	39	F	Mo.	Cholecystectomy.	Recovery.	Frequent attacks of pain for five years. Acute pain, tenderness and fever five days prior to operation. No jaundice.	Gallbladder completely engorged, except peritoneal coat, perforated on liver aspect, contained eighteen pints of pus, surrounded adhesions in surrounding adhesions.	Sharp febrile reaction; discharge of bile from wound up to fifteenth day. Recovery complete.
103	June 26, 1905; General Hospital, St. Louis	42	F	Mo.	Cholecystectomy.	Recovery.	No history of previous attacks. Acute onset of pain, fever, and development of a mass five days before operation.	Gallbladder tensely distended with bile-stained pus. Liver coats completely engorged; cystic duct occluded. Contained many stones.	Recovery prompt and complete. Reported in good health two and a half years later.
104	July 31, 1906; Residence	40	F	Mo.	Cholecystectomy.	Recovery.	Gallstone colic without jaundice twelve years ago; occasional pain at intercostal space. Acute onset of pain, tenderness and fever, and rigidity sixteen hours before operation.	Gallbladder tensely distended with pus; contained many stones, many of them gangrenous at fundus and on the point of perforation. Five straws in peritoneum.	Recovery uneventful except for an abscess in abdominal incision which healed promptly.
105	August 14, 1906; General Hospital, St. Louis	41	F	Mo.	Cholecystectomy.	Death from peritonitis.	Brought to hospital in ambulance with advanced generalized peritonitis of three days' duration. Diagnosed as appendicitis and first incision made over appendix.	Gallbladder gangrenous and perforated; contained three large, small stones. Extensive generalized peritonitis.	Slight improvement after operation (which included free flushing of abdomen with salt solution) for about twenty days. Died forty-eight hours after operation of peritonitis.
106	March 11, 1904; General Hospital, St. Louis	41	F	Mo.	Cholecystectomy; cholecystotomy; hepatic drainage.	Recovery.	Ill for three years with intermittent pain, chills, fever, sweating, variable icterus, and loss of flesh and strength.	Gallbladder shrunken, lacerated in all places, common duct greatly dilated and thickened; contained two half valve stones.	Tube in hepatic duct removed on third day. Bile leakage ceased on second day. Patient perfectly well two and a half years after operation, had gained 40 lbs. in weight.
107	June 16, 1906; General Hospital, St. Louis	42	F	Mo.	Cholecystectomy; cholecystotomy; hepatic drainage.	Recovery.	Attacks of pain, vomiting and jaundice for about one year. No fever, no chills. Pain present every day and jaundice deepening for a month prior to operation.	Gallbladder shrunken around one large stone. Cystic duct in common duct. A large, conical stone in common duct which had nearly obliterated through.	Tube in hepatic duct removed on seventh day. Bile leakage ceased on third day. Recovery prompt and complete.
108	June 25, 1906; General Hospital, St. Louis	43	F	Mo.	Cholecystectomy; cholecystotomy; hepatic drainage.	Recovery.	Operated upon for supposed appendicitis. Jaundice developed after operation and continued, with chills and fever. Refused second operation until June 25, 1906.	Common duct contained a large stone, a perforation was present, sealed by adhesions. Gallbladder shrunken.	Tube in hepatic duct removed on eighth day. Bile leakage ceased on eighth day. Recovery prompt and complete.
109	August 9, 1907; General Hospital, St. Louis	44	F	Mo.	Cholecystectomy.	Recovery.	Violent gallstone colic without jaundice two and a half months ago. Recovery of pain two weeks ago with steadily increasing jaundice, even more.	Gallbladder thickened; perforated on stones. Tissue contained many loculated abscesses. Common duct was milked back into gallbladder before its removal.	Common duct not incised, no bile leakage. Jaundice cleared up rapidly and recovery was uneventful.
110	September 26, 1906; General Hospital, St. Louis	45	F	Mo.	Cholecystectomy.	Recovery.	History of pain, jaundice, and fever in attacks for past eight months. Symptoms more continuous for past year. Weight lost, and loss of flesh and strength.	Gallbladder not incised, no bile leakage. Common duct was milked back into gallbladder before its removal.	Patient made a good recovery from the cholecystectomy and kept the gallbladder intact. All symptoms cleared after several days. Report of some months later was promising to have a relapse.

## POSTDELIRIOUS ALCOHOLIC STUPOR.

*(Alcoholic Cerebral Œdema, "Wet Brain.")*BY CHARLES K. STILLMAN, M. D.,  
New York.

The peculiar stupor that sometimes follows alcoholic delirium has been little studied and less frequently described. In this country it has received attention from scarcely anybody except Dana<sup>1</sup> and Lambert<sup>2</sup>, and although occasionally met with in private practice, is generally unrecognized by the profession at large.

Of late there has been manifested an increased desire for information upon this subject, but the difficulty of obtaining a sufficient number of cases for comparative study has operated against the fulfillment of this desire.

This article, while not pretending to solve the many pathological problems involved, nor to answer in sweeping statements all clinical questions that may be asked, nevertheless represents a certain amount of first hand study under fairly favorable conditions and should have a certain value, if for no other reason than that its rather limited series of cases and observations may serve as a basis of comparison for more complete investigations.

The association of stupor with œdema of the meninges has led many in the past to regard the transudate as the central, if not the causative, factor in this interesting postdelirious state, yet it seems an indisputable truth that the symptoms accompanying are merely those of a certain type of cerebral irritability, for they not infrequently occur in conditions where no traces of œdema are found at autopsy. Thus, in the low muttering delirium of typhoid fever and in the last stages of chronic uræmia is often seen a clinical picture closely resembling alcoholic postdelirious stupor. There are the same evidences of muscular unrest, the same vacuous facial expression, the same pupillary changes, the same hyperæsthesias—all pointing to some profound irritative influence acting upon brain tissue, but œdema of the meninges is not always present in the nonalcoholic cases.

It is worthy of note that these cases are in a low physical state and suffering from cerebral toxæmia.

Conversely, it is interesting to note that considerable degrees of serous effusion of the meninges are found post mortem in cases that during life have given no special symptoms referable to this condition.

The presence or absence of the œdema apparently has little to do in the production of the clinical picture, yet it occurs with surprising regularity in the alcoholic cases; its causation had probably better be looked for among the general conditions underlying the stupor.

The occurrence of marked œdema of the meninges in advanced alcoholics has been generally recognized by pathologists the world over. It may be conceived as beginning in a small way in the simple chronic alcoholic, and rising with successive degrees of intensity throughout the various stages of alcoholism to culminate at last in that condition of which its own presence pathologically is the most striking feature.

It is a matter of a good deal of difficulty to arrive at any just estimate of the causes that contribute to the production of the stupor. Perhaps in view of the undeveloped condition of our knowledge along these lines it may be as well not to theorize at all, but merely to lay emphasis on the probability of a toxic factor and to point out the symptomatic resemblances of this condition to others in which toxæmia and exhaustion undoubtedly play a large part.

The type usually considered in speaking of "alcoholic wet brain" is a transudate pure and simple, and not included under the category of the low grade meningitides. However, there is in alcoholic œdema a tendency to low grade inflammatory changes about the bloodvessels and meninges that is far more marked than in wet brain of other types. Transudation takes place from the piaarachnoid and occasionally from the small bloodvessels penetrating the brain substance. About these latter a small watery zone may sometimes be made out. The changes in the brain substance and meninges are those so often described under chronic alcoholism.

The pathologist should not be too ready to diagnose wet brain in cases where the œdema may well have been post mortem. In true œdema the effusion will be found well distributed, whereas in post mortem œdema the fluid will be found only in the dependent areas.

*Ætiology.*

At the very outset it seems well to lay emphasis on the fact that the symptoms of this type of stupor are almost invariably preceded by a greater or less degree of alcoholic delirium. Dr. Lambert records a few cases where preceding delirium was not noticed, but in the vast majority of instances the previous statement will undoubtedly hold true. The finest examples, naturally, are those in which the symptoms develop following a simple delirium, and it is of these that this paper treats. A second class, in which the wet brain develops following a delirium tremens brought on by pneumonia or some other acute condition, should be worthy of a separate article.

A study of ninety-eight patients admitted to the male and female alcoholic wards of Bellevue Hospital shows some rather interesting results.

From September 1, 1905, to September 1, 1906, there were admitted to the female alcoholic wards of the hospital 2,133 patients; of these but twenty-two were attacked with wet brain, which, after deducting a relatively small number of nonalcoholics from the general total, represents a percentage of approximately 1.

*Nationality.*—Irish, 10; American, 8; English, 2; Canadian, 1; Scotch, 1.

*Age.*—The youngest was twenty-three years of age, the oldest sixty, while the majority ran variously between thirty and forty. There were three between fifty and sixty.

*Mortality.*—Of the twenty-two patients, eighteen died, a mortality of approximately 81 per cent.

*Duration.*—Among those patients who died, the duration of life in uncomplicated cases ranged from one to forty-five days. Of these the three of longest duration, i. e., twenty-four, twenty-nine,

and forty-five days respectively, died apparently of exhaustion. Nine other patients, the balance of the uncomplicated cases, ran variously from two to nine days.

Of the complicated cases where the patients died, the durations were variable. Two contracted lobar pneumonia, one had lobar pneumonia and morphinism, another was attacked with bronchopneumonia. One died with symptoms of postdelirious stupor and pulmonary tuberculosis, but, as there was no autopsy in this case, the diagnosis might well have been tuberculous meningitis.

Of those patients that "recovered," one was taken home unimproved after twenty-eight days. Two were sent to the Department of Public Charities as improved, after sixteen and eighty-nine days respectively, and a third was completely cured after ninety-four days. This young woman, thirty-four years old, now strong and healthy, presented the condition in its most aggravated form.

During the same period, that is, from September 1, 1905, to September 1, 1906, there were 5,017 admissions to the male alcoholic ward. Among this number, seventy-six were attacked with symptoms of postdelirious stupor, or approximately 1.5 per cent. After deducting a small fraction for non-alcoholic admissions, we note that there is still a relative preponderance of the condition among the males.

*Nationality.*—Irish, 24; American, 30; German, 6; English, 3; Swedish, 3; French, 1; Italian, 1; Scotch, 1; Bohemian, 1; Hebrew, 1.

*Age.*—The oldest was seventy years of age, three were between sixty and seventy, fourteen between fifty and sixty, twenty-three between thirty and forty, and four between twenty-two and thirty. Ages of eight others unknown.

*Mortality.*—Of the seventy-six, sixty-three died, a mortality of 79 per cent.

*Duration of illness.*—Among those that died, in the uncomplicated cases, the duration was from less than one day to twenty-two days. The average duration was a trifle under a week, but this does not give a correct idea of the condition. As a matter of fact, out of forty-eight uncomplicated cases, only fourteen patients were over nine days in duration, the longest being twenty-two, twenty-one, seventeen, and fifteen respectively. But twelve were between five and nine days in duration, while the greatest number (twenty-two) was less than five days in duration.

When it is considered that these figures in many instances represent a considerable portion of the preceding active delirium as well, a still further reduction must be allowed for.

Of the complicated cases where the patients died, six succumbed to lobar and three to bronchopneumonia, either coincident or complicating; of these none lived longer than twelve days. One died of decubital gangrene on the fifteenth day, and two who were suffering with simple fractures of the femur on admission died after about a week. In a case with a fractured tibia, the patient survived twelve days.

The thirteen patients who recovered did so in periods of from two to forty-five days. Five of these were of long duration, nineteen, twenty-eight,

thirty-four, thirty-nine, and forty days respectively; eight recovered in periods of from two to thirteen days.

The individual mentioned before who recovered in thirty-nine days exhibited remarkable vitality, as he had two fractured ribs on admission, and was attacked with pneumonia while in the ward. The patient who was discharged after forty days, together with one other where edema was of slightly shorter duration, was committed shortly after as insane.

Of the others, two were sent to the Department of Public Charities as improved, while the remainder were actual or apparent cures.

*Summary.*—In studying statistics, particularly of a small series like the one I have given, great care should be taken not to be led into erroneous conclusions. However, a number of very interesting points are apparent.

It would probably be unfair to cite the slight relative preponderance in males as conclusive, owing to the rather limited number of cases studied. The mortality figures for either sex are not far enough apart to suggest that one sex succumbs more readily than another. Dr. Lambert's records give a considerably lower mortality than these figures would indicate, and I am inclined to believe that the final figures will be found considerably below rather than above the 80 per cent. mark.

The relatively earlier age at which females are subject is borne out also by Dr. Lambert's figures. But there is one peculiar difference that is perhaps a direct consequence of the drinking habits of the two sexes. Men unquestionably survive the shorter attacks better than women, while they succumb with greater frequency to the longer ones. The majority of drinking men punctuate their steady tipping with occasional debauches, which probably have a tendency to bring on delirium tremens earlier than it would have occurred if their efforts had been less spasmodic in character. As a result the attack is more acute but less fatal, because precipitated before their vital powers was entirely used up.

Women, on the other hand, tipple steadily, but debauch less, and this, together with their more sheltered life, staves off the delirium until it results as a direct sequence of physical exhaustion. On these stupor descends with terrible effect, for their vital processes are very low, and resistance almost nil.

In this connection I should like to state that I have seen in men many cases which for lack of a better term I will call *transitory wet brain*, in which the symptoms, manifesting themselves for only a few hours or during the night, almost escape notice. In the majority of cases these have occurred in delirium during a pneumonia, although occasionally in the simple noncomplicated form.

The most interesting feature of these statistics is the tendency which they show toward a separation into two distinct types, the short and the protracted. The short considerably outnumber the protracted. Women, by the way, who last long enough to become protracted cases, show remarkable powers of resistance.

### Symptomatology.

There is no set rule as to the time of onset of stupor in the course of delirium tremens. When the delirium tremens complicates pneumonia, the period of greatest susceptibility is about the crisis, but in general it may be set down that "wet brain" is likely to make itself manifest at about the third or fourth day of delirium tremens, and so insidious and stealthy is its approach that it is hard to determine where one condition terminates and the other begins.

Perhaps the first symptom to attract the physician's attention is the distinct alteration in facial expression. The marked restlessness and noisy activity that characterized the delirium tremens have departed, and his heightened color and exaggerated play of expression have given place to a gray pallor and almost cadaveric immobility of countenance. At this time the pupils are observed to be equally contracted, and there is a moderate degree of stiff neck present. Soon the picture becomes more complete, as the characteristic symptoms unfold themselves. Usually the patient lies flat upon the back with legs extended, head thrown slightly back and unobserving glance directed toward the ceiling, toward which the hands reach in a rather characteristic manner, suggestive of rope climbing. They are seldom still for more than a few seconds at a time, and exhibit the weak, wide tremor of cerebral irritation. The facial expression, aside from its gray pallor, is rather distinctive, and unique in the almost total obliteration of the lines of expression. Dr. Gregory mentions the following points as especially indicative of wet brain: "Line of thought sharply accentuated, yet face totally devoid of expression. Eyes dead, fishy, and lacklustre. Mumbling mouthing articulation in contradistinction to the muttering of other low deliriums in which the spoken words are more sharply defined and clear cut."

Generally the stuporous patients say nothing that is audible. When they talk, as some of the milder cases do, the *labials* are absent, and they appear to suffer from inability to initiate muscular movements of the lips. When irritated or hurt, the accompanying facial contortion involves the least mobility of expression consistent with the recognition of pain. In the majority the eyelids are closed, while flies gather in numbers unheeded about the eyes, nostrils, and corners of the mouth. The pupils in the early stages are often reduced to pin point size and later dilate, remaining so to the end, but this is by no means the invariable rule. Some patients exhibit no pupillary changes whatever, while in one, a case observed in ward 6 in March, 1906, they underwent frequent alterations in size. At times it was even possible to see the slow reactionary changes taking place.

Two, rather constant, early symptoms are muscular rigidity, which is seldom extreme, and hyperaesthesia, the latter particularly marked when circulation to any part is cut off. In time both these symptoms are likely to attract little attention.

Stiff neck, however, is very persistent. In women the writer has many times noticed an ulnar deflection of the fingers, but it is quite possible that this may have been due to the multiple neuritis, so common in alcoholics.

The pulse maintains much the same general features throughout, being small, frequent, feeble, intermittent, of low tension, and very variable in its quality and rate from hour to hour and day to day; indeed, it may run 90 to 100 one hour and 120 to 130 the next, the general average being somewhere between these two figures.

Respirations, on the other hand, are not much disturbed.

Temperature is typically low, 99° to 101° F., and not seldom it drops to subnormal—in general a low, irregular temperature curve.

The stupor is typically a quiet one, except for the muttering movements of the mouth, and the peculiar and continual activity of the hands.

The coma is a very variable quantity; certain cases never become comatose until just before death, when, according to Dana, the filling of the ventricles induces this result. Cases of this sort may remain perfectly rational, talking in mouthy articulation or answering questions until the last.

A second class, passively delirious or comatose, will comprehend if directly addressed, or even obey directions, but relapse with closed eyes into incoherent muttering, if left alone.

A third class remain oblivious to all external stimuli.

As to the course of the illness, there is nothing very definite in the patient's symptoms on which to base a prognosis; perhaps all that can be safely said on this subject is that the cases of short duration greatly outnumber the protracted ones, but do not differ from them so far as the clinical picture is concerned, except in the matter of muscular wasting.

The hold on life which some of the protracted cases seem to have is nothing short of astounding. Under intelligent care they worry along indefinitely, with occasional periods in which life seems completely to be despaired of, periods of weakness and constitutional depression alternating with periods of comparative lucidity and apparent gain in strength until the disease reaches a definite termination.

It is interesting and worthy of note that in these cases gain in strength is sometimes the signal for a new outburst of delirium.

The termination is by death in the majority of all cases. Our investigations, already quoted, placed the mortality at 81 per cent. in females and about 79 per cent. in males.

Exhaustion determines the end of many, while a large number die of complicating pneumonias, both lobar and broncho, and bedsores, the latter a most alarming complication, owing to the patient's almost negative vitality and lowered bodily resistance.

Of those that outlast the edema, a certain proportion develop permanent insanity, while others, actually cured, suffer for a time from mental or bodily enfeeblement.

### Diagnosis.

This is by no means so simple a matter as might at first glance seem evident; unless directly following an attack of delirium tremens, the physician should hesitate about committing himself.

The writer was once so far led astray by appearances as to diagnosticate a case of pernicious malarial fever with meningeal involvement as "wet

brain," the picture for a few hours being identically similar. It is well to remember that any condition where there is cerebral oedema, or any condition in which cortical irritability is the same in degree as in wet brain, may produce a picture that will puzzle the expert. Perhaps the most fruitful source of error among those who have charge of the alcoholic service is tuberculous meningitis, which, while a classic picture in children, may assume in adults more protean forms than almost any disease except syphilis.

I know personally of three successive cases of tuberculous meningitis which came to the alcoholic wards and were diagnosed "wet brain" by competent and experienced men, who discovered their mistake only at the autopsy table.

In general, it cannot be disassociated from tuberculous meningitis in atypical form, except by the presence of a preceding delirium or through finding tubercle bacilli in the fluid drawn off by spinal puncture.

Paretics compensate partially for the reduction in size of their brain tissue by effusion of fluid into the unoccupied cranial space, giving rise to a pathological condition in many respects similar to that in alcoholic wet brain. They, however, die rather typically by going into a convulsion, with subsequent coma, a terminal event which I have never seen in a simple alcoholic.

#### *Treatment.*

Possibly better results are obtained from a system of forced feeding, combined with judicious stimulation, than through any other course.

The whole problem seems to be largely one of vitality and elimination, and happily the stomach accepts large amounts of nourishment and medicine without protest. Unfortunately, it is unlikely that much of this is converted into tissue, owing to the depressed condition of the body functions.

Enormous amounts of food are required, including eggs, egg noggs, liquid peptonoids, and broths, together with powerful stimulation, when the pulse flags and the vital processes get low. The patients do not react to normal stimulating doses; it is surprising to see how much stimulation they can take care of with apparent benefit. The writer has frequently used

B	Whiskey, . . . . .	gr 67
	Camphor, . . . . .	gr. iii
M.	Stychnine, . . . . .	gr 1.30

every three hours for considerable periods, with fairly gratifying results.

Of all the drugs, caffeine is perhaps the most suitable for this class of cases; it may be given as citrated caffeine in five grain doses, or, if so desired, as the sodium benzoate in similar amount.

Very good effects are reported as a result of sitting patients up in bed, it is said to lessen the oedema. Dr. J. D. Peters, late house physician of the first division, reports considerable success with this method.

Tapping the cord produces results for a short time, say a day or so. The relief of pressure or the change in circulation incident to the removal of the fluid seems to cause a temporary accession of

energy, so that a stuporous case may rouse up and assume for a short time the active movements and facies of an earlier stage of the disease. Indeed, there is not infrequently a resumption of active delirium until the fluid reaccumulates.

No permanent results are noted. The fluid removed is usually in increased amount and under increased pressure. Otherwise, it differs in no respect from normal fluid either in appearance or in the distinctive count.

For criticism and valuable suggestions the writer would like to thank Dr. Charles Norris and Dr. A. M. Pappenheimer, of the pathological laboratory at Bellevue; Dr. Alexander Lambert; also Dr. J. D. Peters, Dr. J. H. Cudmore, of the medical staff, and Dr. Paul Waterman, late of the psychopathic department, Bellevue Hospital, as well as the many others whose valuable experiences and observations have added to the material of this paper.

119 EAST TWENTY-SEVENTH STREET.

#### GENERAL PARALYSIS IN THE SENILE PERIOD, WITH A REPORT OF TWO CASES, INCLUDING POST MORTEM EXAMINATION.\*

By MORRIS J. KARPAS, M. D.,

Assistant Physician, Manhattan State Hospital, Ward's Island, N. Y.

#### *Introduction.*

It is generally conceded by such eminent authorities as Kraepelin, Mendel, Ziehen, Wernicke, Kraft-Ebing, Oppenheim, Strumpell, and others that general paralysis is very rare at the extremes of life. The usual run of cases occur from thirty to fifty, and after the fifth decennium it gradually diminishes in frequency. Magnau and Serieux consider the majority of their cases between thirty and forty-five; after sixty this malady becomes rare, and after sixty-five it is exceptional. Arnaud maintains that paresis after fifty-five is infrequent, and a case of that kind at this age needs careful and repeated examinations before the diagnosis as such can be accepted. Christian is very skeptical about senile paresis, and he even rejects the idea of the possible occurrence at this period. M. Dupré is also of the same opinion.

The statistical data bearing on this subject are extremely interesting. Of J. A. Hirschl's 202 cases, 7 were between fifty-six and sixty, and only 2 between sixty-one and sixty-five. Greidenberg found in his 300 paretics 13 over the age of sixty. Rodrigues describes 3 cases of general paralysis which became manifest at seventy. Neamnois speaks in one of his clinical lectures of one subject of general paralysis at the age of sixty-five. Marce analyzed 300 cases with the following results: 3 between sixty and sixty-five, and 4 were from sixty-six to seventy. Bouchereau and Magnau have seen in two years (1870-1871, 1871-1872) 24 women between fifty and sixty, and 15 men between sixty and seventy. Christian and Ritti found in 106 cases of paresis 23 whose ages varied from fifty to sixty.

Magnau and Serieux observed at Sainte Anne Hospital, Paris, 100 cases of general paralysis, 17 of which were over sixty years of age.

from 1886 to 1892, 2,058 general paralytics, and furnished these results:

Age.	Women.	Men.
100	6	199
60-70	8	17
71-80	1	2

In the asylum of Comte de Clamorgan, 700 paralytics were admitted from 1867 to 1896; 14 women and 51 men were between fifty and fifty-nine, and 1 woman and 8 men above sixty. Serge Soukhanoff and Peter Gamouchkin at the psychiatric clinic of Moscow have seen 673 paralytics; among them were 1.93 per cent. between fifty-five and sixty, and 0.45 per cent. above sixty.

Vigoraux and Laignal Lavastine state that of 259 deaths of general paralysis, 12 occurred between sixty and sixty-five. Olivier's investigation in the asylum of Blois showed that out of 139 paralytics only 3 were between sixty and seventy. L. Mongeri in his studies of paresis at Constantinople also furnished analogous results in his 144 cases, 8 at fifty-five, 2 at fifty-seven, and 1 at sixty.

Picket found 2 males and 1 female at the age of sixty out of 113 and 36 general paralytics respectively. Only 2 per cent. of Kraepelin's cases appeared at or beyond sixty.

In Mickel's 2,456 male and 668 female general paralytics, the ages in the senile period ranged as follows:

Age.	Male.	Female.
60-70	3	26
71-80	1	8

Prina observed 23 cases of general paralysis in advanced age. Only in 2 of them did the micro-scope show parietic changes which were suggestive, but *not conclusive*. Merzbacher, in reviewing the article of Prina, questions the diagnosis of general paralysis, and is inclined to regard dementia senilis as more plausible and probable. Alsheimer's analysis of 173 cases of general paralysis gave these data: Eight between sixty and sixty-five years old; 1 at sixty-nine; 1 at seventy. Obersteiner noticed 4.5 per cent. of his cases of paresis between sixty-six and sixty-three.

Olivier collected a number of cases from literature in addition to his own, and he tabulated them under three headings:

I.—Clinical observations without autopsies, 7 cases from sixty to sixty-three.

II.—Clinical observation with autopsies which were limited to macroscopical examination only, 8 cases from sixty to sixty-six, and 2 from seventy to seventy-two.

III.—Clinical observations with autopsies embracing microscopical examination, 4 cases from sixty to sixty-five, and 1 at seventy-two.

The following are complete records of two interesting cases of paresis which came directly under my observation:

CASE I.—Anna H., admitted to the Manhattan State Hospital on May 14, 1904, at the age of fifty-five years; was Assistant Janitor, and died by profession.

Family history: No vesanic or neurotic taint could be established in her consanguineous relations. One son died from alcoholic excess. Daughter in law is an inmate of this hospital and suffering from paresis. Patient presents

Personal history: The patient was born in Austria in 1830. Nothing was known of the development of infancy, childhood, or youth. She was an accomplished la-

profession for forty years. Her diploma was granted by the University of Graz. In Austria she held a position as district midwife. No specific infection could be ascertained or excluded. In 1901 (three years before admission) the first evidences of mental alienation became manifested when she could not attend to her work properly, began to use alcoholic beverages to excess, stated that the neighbors wanted to rob her, would wander at night aimlessly, and complained of insomnia and fatigue. She gradually grew more restless, delusional, and her commitment to Bellevue Hospital was necessary.

At the psychopathic ward patient was described as agitated, restless, and confused. She gave expression to the following: "God keep me. I am dying. I will give you twenty dollars to get me out of here. Let me out to see my son. Oh, oh, oh, oh, I carried him in my arms. You want my death. Let me out. Let me out. Oh, my! Oh, my!"

When admitted here physical examination showed fair nutrition; dilated pupils which sluggishly reacted to light and accommodation; no sensory disturbances; knee jerks somewhat diminished; patellar reflexes normal, tremor of tongue; no tremor of hands; lungs emphysematous; heart was apparently normal; varicose veins. A thorough examination was impossible because patient was too restless and excited.

Mental status on admission: Patient was resistive, restless, excited, pulled her hair, tore her clothing, talked in a loud tone of voice, and showed marked prolixity of speech. The following is a sample of her spontaneous production: Oh, dear! I am doing to die! Send for my son! I am a good midwife—I have the diploma—Oh, give me my clothes—Oh, dear! Oh, dear! I am going to die—they took all my money! Oh, Adolph, what have you done to your mother. Oh, give me a rope—I will hang myself—Adolph, I had only \$500, and they took it from me—I will give you lots of money if you send for my son—I am going to write to the Kaiser—he knows me well."

Occurrences in the ward attracted her attention. The orientation was deficient; she knew the month, but did not know the day or year. She called this place a hospital. She recognized the physician and nurses as such. The integrity of her memory was doubtful, although some statements regarding her life were correct. Mood was that of irritability with frequent outbursts of uncontrollable temper. She spoke of people who tried to rob her and that they wanted to send her away on a farm for the rest of her days. No hallucinations or systematized delusions were ascertained.

For about a year her condition showed, practically little or no change. She was restless, voluble in speech, boasted of her great ability as midwife, asserted that her diploma was signed by Dr. Lorenz, and that she was the most skillful accoucheuse in the United States of America. She stated that she was worth \$50,000. Memory was poor and judgment much enfeebled. Her sleep was disturbed. Her general motor unrest was controlled by hydrotherapeutical measures.

August 21, 1905. She became weak, showed slight ataxia in gait and station (which was attributed to her general weakness and poor sight), and vision was much impaired on account of a double cataract.

August 23, 1905. She became totally blind. Examination at that time revealed marked senile changes, emaciation, dilated pupils which did not react to light and accommodation, tremor of both hands, exaggerated knee jerks, but no speech defect. Mentally, she was restless, tossed herself on the floor, screamed, and shouted at the top of her voice, answered questions irrelevantly, alleged that she had lost her purse, gold earrings, etc., and was in constant search for them. Memory and orientation were very defective. Dr. Ward A. Holden (visiting ophthalmologist to the hospital) examined the patient and found left advanced cataract and right incipient cataract with chorioidal changes about the disk, but the latter was normal.

In October, 1905, patient was quiet, lay in bed, was confused, could not recognize her son's voice, misinterpreted her surroundings, and talked to herself in a low tone of voice.

On November 5, 1905, signs of bronchopneumonia developed, and she died six days later.

After great difficulty an autopsy on encephalon only was obtained. Post mortem examination was performed by Dr. G. Y. Rusk, and showed the following: Increase of cere-

brosipal fluid; pia baggy, cedematous, and diffusely infiltrated and thickened in the frontal and parietal regions, and to a much less extent over the temporal tips; the frontal lobes were moderately adherent; the membranes of the sylvian fossæ were thick and toughened; the pia over the base was slightly infiltrated; convolutions moderately shrunken, and the corresponding sulci widened; the vessels at the base were athrematous; calcarine areas on both sides were normal.

Microscopical examination: Sections from paracentral and second frontal and gasserian ganglia showed definite changes, consisting of pial, cortical, and subcortical perivascular infiltration with plasma cells, among which were relatively few lymphocytes. There was a moderate perivascular pigment accumulation and moderate pigmentation of cells. Rod cells occurred in frontal sections. Glia hypertrophy subpially and in depths of tissue was marked, and particularly in the regions of the second frontal convolution.

CASE II.—This patient was also under the observation of Dr. L. C. Pettit, Dr. J. R. Knapp, and Dr. J. L. Pomeroy. The patient, Sarah C., was admitted to the Manhattan State Hospital on June 1, 1906, at the age of seventy. She was a widow, born in the United States.

Family history: Family history was negative for psychopathic and neuropathic traits. Maternal uncle died from apoplexy.

Personal history: Patient was born in New York in 1836. Little was known of her early life. She was always considered bright, cheerful, intelligent, and suffered from no physical ailments except that she was subject to rheumatism. She was married; gave birth to nine children; three died and six were living and enjoying good health. Her husband died from pulmonary tuberculosis in 1881. She did not indulge in alcoholic beverages, led a moral life, and luetic infection could not be demonstrated. For the past five years she worried a great deal over domestic troubles.

There were no manifestations of a mental disorder until the latter part of November, 1905, when it was noticed that patient made peculiar motions with her mouth; would put kittens into the oven, thinking she was roasting turkey; would talk in a rambling manner; imagined she had lots of money; later developed a mania for borrowing a dollar from her friends, relatives and strangers; was particularly fond of counting her money. On one occasion she fell at Crotona Park; she was then unconscious and was taken to Bellevue, where she remained a few days, and subsequently discharged to the care of her daughter. In February, 1906, she had an attack of cerebral apoplexy; she was unconscious for two hours. Since then and till the time of her death she remained a bedridden invalid. The mental symptoms remained unchanged until her removal to Bellevue Hospital.

At the psychopathic ward patient was described as confused, talked in a disjointed manner, reacted to auditory and visual hallucinations, asserted that she owned elephants and horses and that an elephant was in her stomach. She said: "I am too old to work—I have no money—I can lay my hands on fifty thousand dollars—I played the races and made lots of money—I paid a thousand dollars for a white elephant. He goes out every day and I keep him in Central Park. I paid a thousand dollars for a horse. I have three elephants in my stomach; they are all in gold. I own ten horses uptown—I bought them—I made the money on the horses. Every time I get short I raffle off a horse."

Upon admission her physical examination revealed poor nutrition; unequal, irregular pupils which did not react to light and accommodation; anosmia, knee jerks not elicited; ankle jerks diminished; other reflexes not established; drawing speech; enlargement of the heads of both tibias with grating sounds and stiffening of both knee joints; umbilical hernia; chronic myocarditis; arteriosclerosis; pulmonary emphysema.

Mentally patient was quiet, well behaved, appeared happy and contented, and talked in an incoherent strain. The following is a sample: "Since I was a girl I have seen this policeman. I married him, he owned a house on Central Park, and I was a very handsome woman. If you knew how sister looks then you know how I look. I have got my train which I wore in the theatre when I was a young girl. I was a school teacher all my life. I get my

pension every year, one hundred and twenty-five dollars, all in gold."

The answers to questions will fully illustrate her peculiar trend of thought:

How do people treat you? "First rate—I can't complain."

Anybody annoy you or talk about you? "Nobody ever talks about me now; my son-in-law was a drunken bum and always licked me."

Did you ever hear voices? "No. Sometimes I scolded her for living with this man."

Do you ever see strange things? "Yes, I see him often. He appears to me because I killed him. He was so old he sat in a chair. I often see him at night time. His name was Phil Lee. I cut his head off and his belly off, and I threw him in the river."

Does he ever talk to you? "What I ate to-day was sturgeon. He ate him up. I get his interest."

Have you any money or property? "Oh, my goodness, yes. Didn't I tell you I was worth a hundred thousand dollars? I own the underground railroad from New York to Albany, from Albany to Boston and to Buffalo, and all around New York and around the west side. I own Central Park. I own Bedford Park. I own that house there where that policeman is. I will get twenty dollars to-morrow; I am going to give you forty out of it for taking care of me all this winter."

Mood showed no variability; she expressed the feeling of well being. Orientation was very deficient; she called the place New York Hospital; gave the date as 150; year 90; the month May. Data of personal identification and the memory for the remote and recent events were very much impaired. Judgment exhibited marked enfeeblement.

June 19, 1906. Lumbar puncture performed; cerebrospinal fluid showed chemically serum, albumin in abundance, and microscopical examination revealed a marked lymphocytosis (100 to 150 in a field). Another examination of the cerebrospinal fluid was made, and similar results were obtained.

The patient was examined several times by the writer, and she practically presented no change in her general mental attitude. She spoke in a rambling manner, expressed ideas of grandeur, asserted that she was worth millions of dollars, owned property, parks, etc. Orientation and memory were very defective, and in general she appeared to be simple and childish. Physically she showed diminished knee jerks, articular hypertrophy of both knees, small, irregular, and unequal pupils which did not react to light and accommodation, drawing speech, marked arteriosclerosis, and slight residuals of hemiplegia dextra.

Her physical condition gradually declined. On November 8th, patient had a general convulsion which lasted several minutes. After this she remained unconscious and expired four hours later.

Great effort was exerted to obtain a necropsy, and fortunately a consent was granted, but restricted to the calvarium only. Autopsy, performed by G. Y. Rusk, revealed the following: Increase of cerebrospinal fluid; examination of the pia negative throughout except for slight milkiness over the vermis of the cerebellum and closely following the principal ramification of the sylvian artery, and slight diffuse thickening over the mesial aspect of the frontal lobes; moderate degree of diffuse atrophy of the convolutions with slight accentuation in the frontoparietal and temporal regions; atrophy was more marked on the left than on the right hemisphere; the orbital surfaces of the frontal lobes also showed atrophy; two small subpial cysts occurred at the beginning of the interparietal fissure between frontal, second, and third, just above Broca's convolution; frontal and temporal tips were slightly adherent; the floor of the fourth ventricle showed a diffuse granular appearance; the basal artery at its bifurcation was athrematous; carotids and middle cerebral arteries were large and moderately athrematous. Sections examined from anterior and posterior central, first frontal, angular regions, and cerebellum showed pial and perivascular infiltration with lymphocytes, plasma cells, and an occasional mast cell. In all these areas a fair amount of elia overgrowth with few cells possessing prominent nucleoli, and the nerve cells were not excessively pigmented, but there was an abundant accumulation in the perivascular sheaths. The walls of the arterioles were thickened and hyaline deposition occurred. Rod cells were numerous in the frontal and temporal regions, especially in the latter.

## Remarks.

The mental picture of paresis in the advanced period bears a striking resemblance to dementia senilis. The onset of the psychosis is marked with intellectual enfeeblement, and the delusions are relatively rare. The grandiose ideas are not prominent (Olivier and Obersteiner). In both of my patients delusions of grandeur were present, and especially in Case II they were markedly accentuated. It is to be remembered that in the latter the usual boastfulness, which is so common to paretics of that type, was wanting. Some of the morbid ideas in patient Anna H. were analogous to those of senile dementia. For instance, she asserted that she was robbed of her property, and was in constant search of her lost purse and jewels. Each of my patients presented many stigmata of senile dementia.

Illusions and hallucinations are seldom manifested, and in my cases these symptoms were not observed.

There are no special somatic signs which stand out prominently in the disease picture, but they may be obscured by the usual physical changes common to senility. Convulsive seizures are not common (Olivier). In one of Hirschl's cases optic atrophy was present. My patients manifested no atypical features except in Case I the speech was fairly well preserved through the disease.

The duration of the mental malady is relatively rapid (Obersteiner). However, in my first case the course was rather exceptionally long, five years.

The diagnosis of general paralysis in the senile period is very difficult. Quite often such cases are mistaken for senile dementia, and, indeed, in some instances the differential diagnosis between these two maladies is impossible without the aid of the cytological examination and necropsy.

My hearty thanks are due to Dr. William Mabon, superintendent of the Manhattan State Hospital, for the permission he has given me to publish these two cases.

SECONDARY HÆMORRHAGE NINE DAYS AFTER  
HÆMORRHOIDAL OPERATION. SCIATICA  
' COMPLICATIONS.\*

By D. H. MURRAY, M. D.,  
Syracuse, N. Y.

CASE: The patient was an American, 48 years of age, 6 feet, 2 inches high, weight 185 pounds. Previous history was negative.

Present complaint: Bleeding internal hæmorrhoids which had given him trouble for more than ten years. For the past two years he had been troubled from time to time with sciatica, for which he had received various kinds of treatment, including stretching of the nerve, but he grew gradually worse, the attacks came on without apparent cause and were worse in the morning on arising.

Six weeks previous to his consulting me, a physician in his home town gave him special treatment for sciatica. This was given during three sittings, two days apart. At the first sitting he was given six hypodermatic injections, of atropine 1/150 gr. each, into the sheath of the sciatic nerve. Two days later he was given seven hypodermatic injections of atropine, the same amount, which caused intense nervousness. Two days later than this he was given nine hypodermatic injections of atropine, same amount, eight of these being into the sheath of the nerve, and one of these injections was given, or attempted to be given, into the nerve before it leaves the pelvis. Following this third sitting he became unconscious and remained so for fourteen hours; since the completion of the last sitting he had been especially nervous, and said his heart had been very weak. He experienced a little relief at the time, but occasionally had severe attacks of pain.

On November 24, 1906, he began bleeding profusely, which had kept up until his visit to me. Examination showed very large internal hæmorrhoids all around the pile bearing area, from one of which a large stream of blood of arterial origin was emitted. Inasmuch as he, owing to business reasons, could not be operated upon at once, I tied this vessel. The next day he called at the office and felt somewhat better, had no pain, slept well.

On December 11, 1906, he entered the Hospital of the Good Shepherd, where I operated upon him on the 12th. I dilated the sphincter carefully and removed all internal hæmorrhoids by the clamp and cautery combined method, which consisted in dissecting the hæmorrhoidal tumor out as though it were to be ligated, but instead of ligating, used the clamp and cautery to complete the removal of the tumors. Two bleeding vessels were ligated at the time of the operation. I packed the anal canal with iodoform gauze and put the patient to bed in good condition, except that his pulse was slightly weaker than normal. He had no vomiting, but some discomfort until 6 p. m., after that he rested quite comfortably. The patient was making a good recovery with no complications until the ninth day after the operation.

December 21st, at 10:30, I was called, being told that the patient had a hæmorrhage which had begun at 8:45. The internes at the hospital had done what they could to check the hæmorrhage without avail.

I went immediately to the hospital and found the patient almost pulseless, gave a small amount of ether, inspected the parts, and found that a branch of the superior hæmorrhoidal artery was pouring a stream of blood into the rectum. The artery was secured, the patient stimulated, to which he responded promptly. The quantity of blood lost was, by measure, forty-five ounces. The blood count two days later was 3,270,000 red corpuscles, 7,000 white corpuscles, hæmoglobin 70 per cent.

On January 1, 1907, he was allowed to sit up, and a week later to go home.

Since the operation the patient has never had a twinge of his sciatic pain, which leads me to remark that, as is well known, many cases of sciatica are symptomatic.

The hypodermatic treatment which this patient received may have been a good treatment for some cases. It is quite evident, however, that in this case the rectal conditions were paramount.

It is very important that physicians, whether doing surgical work or not, should note all rectal and

pelvic diseases. It is well known that such conditions often produce symptomatic sciatica and should be considered in distinctive diagnosis.

To me, it is quite a serious matter that injections of atropine, in the amount used in this case, should be given to any patient, when there is a palpable rectal or pelvic disease existing, that may be the cause of sciatica, as in this case.

I am not able to explain the cause of so severe a secondary arterial hæmorrhage as late as the ninth day after the operation, unless a thrombus or eschar became dislodged. I have had, three years ago, one patient with a moderate secondary hæmorrhage on the eleventh day, but in that case pressure controlled it without trouble. In a speculative way I have wondered whether the atropine, with its paralyzing effect on the vasomotors, could have been in any way responsible for the secondary hæmorrhage.

800 UNIVERSITY BLOCK.

#### DELAYED LABOR.\*

By WALTER B. JENNINGS, PH. B., M. D.,  
New York.

The length of normal labor varies within wide limits, and, while different authorities differ in regard to time, the average duration of normal labor may be taken as eight hours in multiparæ, while in primiparæ the time is usually double that or longer.

Table of average duration of stages of labor (Spiegelberg):

	First stage.	Second stage.	Third stage.
Primipara . . . .	15 hours,	2 hours,	1½ hour;
Multipara . . . .	8 hours,	1 hour,	½ hour.

Normal labor is longer, as a rule, in the very young and in old primipara, i. e., extremes of child bearing life.

What, then, is meant by delayed labor?

**Definition.**—Delayed labor may be defined as one in which the frequency, strength, duration, and expulsive character of the uterine pain has been so changed as to prolong the second stage of labor, so that either the life of the mother or that of the child is endangered.

In considering this question, Dr. J. F. Moran, of Georgetown University, Washington, D. C., says that "It is impossible to separate the cases dependent upon uterine inertia from those due to many different pathological states." In the first stage of labor one of the most common causes of delayed labor is a rigid cervix due to old inflammatory conditions, malignant disease, or cicatrix. These cases, however, would not be classed with those of delayed labor in the true sense of that term, but are due to some abnormality of the soft parts. Consequently, there is reason for classifying delayed labor by itself, whether complete or partial, as due to some perversion of the normal power concerned in expelling the fœtus. It is the writer's intention to consider briefly uterine inertia, consequently the many varieties of pelvic deformities are excluded. While his condition might possibly occur in contracted pelvis, tetanic uterine contractions are more liable to be encountered.

**Ætiology.**—The causes of uterine inertia are local and general.

**Local Causes.**—It is generally admitted that the uterine muscles possess a certain amount of intrinsic contraction, and any condition causing a disturbance of the uterine muscle would tend to bring about this condition. Multiple pregnancy causing a loss of tonicity, uterine tumors, excess of liquor amnii causing overdistention, are among the local causes generally given, as well as overdistended bladder or rectum. Occasionally a soft sagging uterus markedly bent forward, together with a pendulous abdomen, will interfere with the action of the uterus.

**General Causes.**—Among these are general lowered condition of the system—rapid child bearing, anæmias, and wasting disease. Certain psychic and emotional disturbances may also have some effect upon uterine contraction reflexly through sympathetic nervous system. Fatty changes and atrophy of the abdominal muscles or separation of the recti often lessen the expelling forces and so delay delivery.

Very frequently defective abdominal contractions are due to fear of increased pain on the part of the patient, and in this way the patient does not bring her abdominal muscles into full play. In such a case the administration of chloroform dulls the sensation of pain, and the patient, unconsciously or semiconsciously, uses her abdominal muscles, with a very happy and gratifying result. Uterine inertia sufficient to cause delayed labor is of comparatively frequent occurrence. Acconci, from a study of over 2,000 cases, says that it occurs in 6 per cent. of cases. It has been suggested that uterine inertia might be the cause of prolonged gestation.

Uterine inertia may be characterized by feeble and infrequent contractions, or there may be a marked disproportion between the pain and contractions. Unfortunately, there is no standard by which the character of labor pains can be measured.

Clinically, however, the efficiency of uterine contractions may be measured by their effect upon the progress of labor. In normal labor, the contractions of the uterus occur infrequently in the early stages and gradually increase in frequency, intensity, and duration until labor is terminated.

Many cases of labor begin in the regular way and give every promise of an early termination. The cervix is fully dilated and obliterated when the pains stop and labor comes to a standstill. In many cases prolonged labor is commonly said to be due to the undilated cervix, when, as a matter of fact, it is due to a faulty uterine contraction (primiparæ over thirty-five are exceptions). In other words, the majority of cases of delayed labor are not due to the resistance of the soft parts, but to a lack of the *vis à tergo*.

Delayed labor is of little importance in the first stage, if the membranes have not ruptured, but during the second stage the life of the child is endangered, and if it occurs toward the end of labor, post partum hæmorrhage may take place. There is no fixed and firm rule regarding the duration of labor in cases of inertia. Cases have been reported when the liquor amnii has escaped thirty-nine days before labor began, but during the second stage of labor, with a dilated cervix and the head engaged, delayed labor is not usually allowed to take a natural course, two thirds of the cases being instrumental.

\*Read before the Section on Obstetrics and Gynecology of the New York Academy of Medicine, November 26, 1907.

The writer has collected a series of forty-five selected cases of primiparae, in which twenty-five cases were instrumental, fourteen cases were in labor from twenty-four to forty-eight hours, one case labor was induced, the patient being three weeks over time, and two cases were breech presentation. Among the remaining cases, one was in labor eighteen hours, five fifteen hours, four thirteen hours, and eleven ten hours or less. Of the fourteen cases that were in labor twenty-four hours or longer, ten were instrumental.

Omitting for the moment the question of uterine inertia, the writer wishes to call attention to another class of cases, in which labor pains continue for several hours, progress is comparatively slow, and the woman is on the verge of exhaustion. These cases generally occur in the hands of the general practitioners. The fetal heart becomes very rapid, and the life of both mother and child are endangered.

*Treatment.*—The value of manual dilatation of the cervix in cases of uterine inertia has been disputed. Playfair recommends sweeping the finger around within the cervix to separate any adhesion. Some obstetricians use instrumental dilatation.

During the first stage, quinine, strychnine, and sugar have been used with varying results. In regard to the latter (sugar), the writer has had no experience, but that this idea is not a new one is certain. In looking over an old English translation, taken from the Latin, Rhodion's *De Partu Hominis* (translated as early as 1538), he can hardly refrain from referring to an old superstition. To quote: "Eating sowre fruites, quinces, crab apples, chestenuts, as well as things of great odour, smel or savor, hinder byrth."

In regard to quinine, differences of opinion have long existed among obstetricians as to the value of this drug as an oxytocic. A comprehensive summary of these conflicting views is found in the *Deutsche medizinische Wochenschrift* (January 31, 1907), by Mäurer, who reports his experience with quinine in sixty-three cases during labor and fifteen times in the treatment of abortion. He found that in 78 per cent. quinine gave results, while in 21.8 per cent. there was no effect. It was found that the nature of the quinine preparation was of no importance, and that it might be given by mouth or hypodermatically.

Pressure upon the fundus of the uterus, as suggested by Krishaber, is of benefit in certain cases. In the second stage of labor, after full dilatation and the head in the pelvis, forceps should be applied, as many hours of suffering to the mother, as well as danger to the child, will be avoided.

While the writer is a firm believer in conservation in all things, particularly in obstetrics, and of the great need in giving Nature a chance, however, in selected cases (and each case must be studied separately), he believes in early application of forceps in the second stage of labor.

*Conclusion.*—In conclusion the writer wishes to state that he believes the woman about to become a mother has the right to demand every alleviation from suffering which medical science has provided, such as anaesthesia, asepsis, and rapid delivery.

Given a case of labor with the os uteri fully dilated and obliterated, ruptured membranes, empty bladder and rectum, and asepsis, no abuse is possible.

The time at which forceps should be applied depends upon the conditions that arise in each case. It is the writer's rule to use instruments when no progress has been made for two hours. Dr. D. M. Aitkins, of London, said that cerebral hemorrhage was more likely to be obviated than caused by the early use of forceps.

The old idea, and one rather common among general practitioners, to wait until signs of danger to the mother or child were present, was decidedly erroneous.

#### A UNIQUE CASE OF INFECTIOUS ORCHITIS.

By JOHN GILLESPIE BEARDSLEY, M. D.,  
Philadelphia.

It is well known that, during or following certain infectious diseases, orchitis or orchitis complicated by epididymitis sometimes occurs. The most frequent diseases in which these conditions are seen are parotitis, variola, typhoid and paratyphoid fevers, Rocky Mountain or tick fever, and in Mediterranean fever, which latter disease is also known under the names Malta fever, Gibraltar or Rock fever, or when seen in Italy as Neapolitan fever.

Before the septicæmic condition of the blood in these diseases was discovered, many different theories were advanced to explain the occurrence of orchitis in them, and the favorite explanation of the condition was that because of the lessened resistance of the individual by the presence of primary disease there had been a recurrence of a former gonorrhœal infection. Other cases were explained by slight trauma, such as would be brought about by a careless orderly in aiding the patient to use a urinal or bed pan, and still other cases were said to have been "rheumatic" in origin.

When careful researches and investigations were conducted to ascertain the condition of the blood in some of these conditions, notably typhoid and paratyphoid fever, it was found that in the great majority of the cases a bacteriæmia existed. Not only was this true, but study of the excretions revealed the fact that the germs were being eliminated by the urinary tract as well as by the intestine, and thus it became much more reasonable to believe that the orchitis was caused by the germs of the primary disease, which were carried to the testicle in the blood stream, and that because of some lowered condition of resistance in a focus in the testicle inflammation was brought about. In certain cases, also, there seems at least a likelihood that the infection may have been brought about by the presence of bacilluria, with infection of the testicle by way of the vas deferens.

The case to be reported was so unusual that it seemed of interest to report it.

*CASE.*—A girl, nine years of age, was under my care for a well marked case of bilateral parotitis. There was considerable constitutional disturbance but no complications, and the patient soon recovered. During the time of the girl's illness her mother remarked that a brother of the patient,

who had been in the country, was on his way home, and requested me to give him medicine to prevent the disease. I did not see the boy at this time, but left a prescription for an antiseptic mouth wash, with directions to use several times a day and to stay as far removed from the sister as possible, but as the house was small and the opportunity for isolation poor, I had little doubt that the youth would contract the disease. Eight days after the boy's return home I was called to see him and found a boy, eleven years of age, with a temperature of 102° F., no pain or swelling in either the parotid or submaxillary glands, but a marked swelling of the left testicle, which was extremely tender to the touch, and the skin of the scrotum over which was decidedly reddened. The boy recovered completely in four days, and there was no difference in the size of the testicles. There had been no urethral discharge or no history of trauma, and as far as could be learned, no exposure to parotitis until his return home eight days before.

Cases of parotitis have at times been reported, especially in epidemics, in which the swelling of the gland was very slight, and among them a few cases in which the parotiditis became visible only shortly after the patient was allowed to take fluid, but, as far as I have been able to find in the literature (if we grant the possibility of the orchitis being caused by the infectious principle which causes parotiditis), this case is unique, although Osler mentions the fact that such a condition has been seen.<sup>1</sup>

2030 CHESTNUT STREET.

# REPORT OF A CASE OF HYSTERICAL RETENTION OF URINE, COMPLICATED BY FOREIGN BODY.

BY FREDERIC BIERHOFF, M. D.,  
New York,

Attending Physician, German Dispensary, Dermatological Department; Corresponding Member, l'Association Française d'Urologie; attending Genitourinary Surgeon, West Side German Dispensary, etc.

While pollakiuria is not at all an unusual condition to be met with in either neurasthenic or hysterical patients, retention of urine of nervous origin is comparatively rare. Von Frankl-Hochwart states that in an experience with hysterical cases, covering a period of eighteen years, he has only seen this anomaly four times, and reports several interesting cases of this condition. He further states that, in cases of this character, he has received the impression that masturbatory tendencies frequently form the basis of the wish to be catheterized, and that, as a result, the rule should be to delay the use of the catheter as long as it is possible. Furthermore, that one can do this so much more easily than in cases of retention of urine due to other causes, since the unpleasant symptoms which usually accompany retention of urine are usually wanting in hysterical retention.

The following case belongs, I believe, to the class of hysterical retention, even though it was complicated by the presence of calculi, for these I believe to have exerted an influence only of recent date, and then not toward retention, while the history of the nervous disturbance dates back over a number of years—in other words, I believe the calculi to have simply complicated the condition, but not to have been a factor in causing the retention. Un-

fortunately, it was impossible for us to have the patient's nervous system more carefully examined. The history of the case is as follows:

The patient, Miss C., aged twenty-six, was sent to me for examination, by Dr. Greeff, with the statement that, during the two weeks previous to his sending her to me, she had been unable to void urine at all spontaneously. She had, at one time, passed two days without urinating, at the end of which time she was catheterized. Following this, she was catheterized daily, large quantities of turbid urine being withdrawn. Upon one occasion catheterization was accompanied by the passage of a slight amount of blood. She stated to me at the time of examination that she had, since several years, had similar attacks of inability to void any urine at all. These attacks were recurrent at intervals of about three months. She further stated that at times three to four days would elapse without her being able to void any urine, at the end of which time she was forced to seek medical aid for catheterization. Only once or twice in all had these attacks occurred about the time of menstruation. In June, 1906, following an operation for appendicitis, retention again occurred, requiring regular catheterization for a period of two weeks.

The patient was a well grown female, although of slender build. While in my waiting room she had several attacks of weeping, and even simulated unconsciousness. The pupils were rather dilated, and the face considerably flushed. As soon as she recognized the fact that I knew her to be shamming-unconsciousness, she sat up and did not attempt the deception again during the entire time that she was in my office. She stated, upon questioning, that she was subject to frequent attacks of crying, and her brother, whom I questioned, stated that this had been the case ever since her childhood; also that she frequently "fainted." She also complained of pain in the abdomen, particularly in the region of the umbilicus, and that she had not been able to pass any urine whatever, in spite of repeated attempts, during the twenty-four hours preceding her visit.

Examination revealed a markedly distended bladder. The labia minora were decidedly hypertrophied, which condition led me to decide that the patient was a masturbator. There were no evidences of discharge, or of inflammation about the vaginal or urethral orifices, and the hymen was intact. A catheter was passed, and 1,600 c.c. of turbid urine of an alkaline reaction were removed. The bladder was thoroughly cleansed, and a cystoscopic examination made, which revealed a generalized cystitis of moderate grade, also the presence of a whitish, foreign body, diagnosed as being of calculous character, situated in the left lateral bladder pocket.

The patient was referred to Dr. Ewald, at the German Hospital. Through his kindness I was permitted to examine and operate on the woman at the hospital. A second cystoscopy was made under general anesthesia. During the process of cleansing the bladder and subsequent thereto, but previous to the beginning of narcosis, in all during a period of about thirty minutes, the patient repeatedly went through movements which were clearly masturbatory in character, terminating, apparently in each instance, in an orgasm. The insertion of the cystoscope made it possible to recognize the presence of two foreign bodies, the larger of which could be easily recognized to be a button, encrusted with saline deposits, the thread holes being plainly recognizable. This larger foreign body was seized with a lith-trite and easily removed. It was a bone button 1½ cm. in diameter. An attempt was then made to remove the smaller body by means of the evacuator. It was at first found that the foreign body, or calculus, engaged in the mouth of the evacuator, but would not enter the bottle. Fragments of calculous nature, however, broke away. Attempts to seize it with the lithotrite were then made, but did not succeed. The cystoscope was then again inserted, and the foreign body was found to be floating upon the surface of the filling fluid. Being unable to recognize the character of a calculus which would float, and recognizing my inability to manage it with the lithotrite under those circumstances, I determined to attempt to remove the body by engaging it in the mouth of the evacuator. This was again attempted, and upon passing the evacuator with the foreign body it was found that the latter consisted of a piece of cork, 1 cm. long by 1 cm.

<sup>1</sup>After writing this article I find that Mr. T. J. C. of Boston, reported in the *Lancet* of January 10, 1908, that three cases of orchitis occurred in a troop of boys, and that the boys had been exposed to parotitis during a period of four days, in epidemic of this disease, the orchitis being from fourteen to twenty-one days.

thick, encrusted with saline deposit. The concretion upon the button and the piece of cork was found to be of phosphatic character.

The patient was placed upon urotropin, internally, and the bladder was washed out with a solution of boric acid, followed by a silver nitrate solution, increasing gradually in strength from 1 in 2,000 to 1 in 1,000. For the subsequent report of the case I am indebted to Dr. Ewald.

He states that twenty-four hours after the operation the patient had no further vesical symptoms; that she could pass urines; furthermore, without any pain whatsoever. That upon the fifth day following the operation the urine, which had previous to the operation been very turbid, and which had contained large numbers of pus corpuscles, a moderate number of vesical epithelia, and large numbers of bacteria, now showed only a few vesical epithelia and pus corpuscles. On the sixth day following the operation the patient left the hospital, having been able to pass her urine normally during this time. Five days later she presented herself for control to Dr. Ewald and stated that she had experienced no further symptoms whatever. Upon inquiry, she absolutely denied masturbation. Informed of the character of the foreign bodies discovered in her bladder, she denied having inserted them, and stated that her only knowledge of the matter was that, one time, quite a while ago, she had *swallowed a button*.

51-53 EAST FIFTY-EIGHTH STREET.

### Our Readers' Discussions.

#### A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXX.—How do you distinguish alcoholic stupor from other conditions resembling it? (Closed January 15, 1908.)

LXXI.—How do you treat gallstone colic? (Answers due not later than February 15, 1908.)

LXXII.—How do you treat fracture of the patella? (Answers not later than March 16, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXIX has been awarded to Dr. Maurice A. Walker, of Dillon, Montana, whose article appears below.

#### PRIZE QUESTION NO. LXIX.

##### THE TREATMENT OF POST PARTUM HÆMORRHIAGE.

BY MAURICE A. WALKER, M. D.,  
Dillon, Montana.

In the preventive treatment of post partum hæmorrhage, there are several measures which are of value. One of the most important is the avoidance of protracted labor, which by wearing out the patient and the uterus tends markedly toward uterine inertia. If there are weak and ineffectual, but real, pains, chloral hydrate, gr. xv, repeated, if necessary, in an hour, will often give the patient a good rest, and so strengthen the force and add to the effect of the uterine contractions.

Use the forceps in such a case as soon as the os is completely dilated, giving as little chloroform as possible, even none at all, if, as in most multiparæ, the

parts are easily distensible, so as to make an easy median or low forceps operation.

Avoid the use of quinine to stimulate contractions, as it seems to predispose to inertia after the birth of the child. Avoid chloroform in slow labors, no matter how painful. This valuable agent should not be used simply for the comfort of the patient, but only in normal or rapid labors.

In very rapid—precipitate—labors, with forcible contractions, the use of an anæsthetic will tend to prevent that form of post partum hæmorrhage which comes from a lacerated cervix, vagina, or perinæum.

After the birth of the child, the physician should keep his left hand constantly applied to the fundus uteri to maintain the contraction of the organ and to discover if there is relaxation, which tends to allow hæmorrhage into the uterus itself, concealed hæmorrhage.

If hæmorrhage begins during the period between the birth of the child and the expulsion of the placenta, and without evident relaxation of the uterus, it may be due to partial separation of the placenta, or to the fact that the placenta is separated, but still within the uterus. Slow, rotary kneading or the more active Crêdè method of expression of the placenta will usually stop the flow by removing the obstacle to perfect contraction and directly stimulating the uterus to contract.

Failing to thus remove the placenta, and the bleeding continuing, place the woman across the bed in the lithotomy position, with hips at the edge of the bed and a Kelly pad in place. You now have easy access to the source of trouble. Introduce the sterile right hand into the uterus and remove the placenta by peeling it off. In any case, normal or otherwise, I give a full dose of ergot as soon as the placenta is delivered, either by the mouth or by the hypodermatic use of one of the preparations made for that purpose.

If there is hæmorrhage from inertia of an empty uterus I give a rapid douche of hot sterile water or weak creolin solution, and for this purpose always have prepared, hanging up and ready for use, with sterile douche tube attached, a four quart fountain syringe with a solution hotter than can be borne by the hand, about 120° F.

Bleeding continuing from a contracted uterus may be due to the presence of portions of placenta or membranes or of clots, which prevent closure of the uterine sinuses in some comparatively small area. Remove clots by expression and large pieces of placenta or membranes by the internally placed hand.

All other available methods of treatment failing, introduce a speculum and pack the uterus and vagina with sterile gauze, which should be in readiness for immediate use at all confinements.

Hæmorrhage immediately following the birth of the child may be from the circular artery of the cervix, from a lacerated vagina, or a lacerated perinæum. If this form of hæmorrhage occurs, the speculum should be used, and with a stream from the douche bag constantly washing away the flowing blood, apply such local treatment as may be necessary, this meaning, usually, immediate repair of these lacerations, placing stitches in such a way as to constrict the bleeding points, which are usually easily found.

*Dr. Henry B. Bryan, of Philadelphia, remarks:*

When in attendance on a labor case, I always prepare for a post partum hæmorrhage, having in readiness beforehand a good syringe, either a Davidson or gravity bag syringe, brandy, sulphuric ether or chloroform, carbolie acid, ergot, a solution or morphine, a jar of iodoform gauze, a hypodermatic syringe filled with fluidextract of ergot, a uterine dressing, forceps, and dilating uterine douche, also bichlorid of mercury tablets,  $7\frac{1}{2}$  gr.

These articles I carry with me. All pitchers, basins, bowls, slop jars, bed pan, etc., having been sterilized, plenty of hot water ordered and at hand, we have practically begun the preliminary treatment.

Of course I always look to the prophylactic measures during gestation, meeting and treating any abnormal condition by proper medical, dietetic, and hygienic measures.

When the hæmorrhage occurs I immediately grasp the fundus uteri through the abdominal wall, after the method of Crêdè for expressing the placenta to secure contraction, while an assistant injects hypodermatically a drachm of fluidextract of ergot.

Let the nurse give a dose of ergot by the mouth and put the child to the breast, all of which will tend to contract the bleeding uterus.

The foot of the bed may now be raised by putting anything which may be at hand under the legs; it will tend to carry the blood by gravity to the upper extremities.

Should the uterus not contract and the hæmorrhage continue slightly, give a vaginal douche of hot water or sterile salt solution,  $115^{\circ}$  to  $120^{\circ}$  F. If the bleeding still continues, put the uterine douche on the syringe and allow a similar solution to flow into the interior of the uterus, holding on to the uterus all the time; if necessary the assistant may use both hands and strong pressure.

If the hæmorrhage still continues, especially if it is profuse, I grasp the fundus uteri on the outside with one hand; the other hand, without hesitation, I pass quickly and gently into the vagina and uterus and press the sides of the uterus between my two hands, gently twisting the hand inside so as to irritate the womb and produce contraction, feeling at the same time for clots, pieces of membrane, or the placenta, and remove them.

Failing still to stop the hæmorrhage, I perform the "bimanual manipulation" described in all books on obstetrics, and usually accomplished by passing the two fingers of the right hand high up along the posterior wall, pressing the lower segment and cervix forward toward the symphysis pubis, at the same time pressing the fingers of the left hand deep in between the umbilicus and uterus, so that the hand on the outside, the fundus resting in the palm of this hand, may be pushed downward and forward against the pubes, thus forming a sort of temporary antelexion, whereby the canal of the neck is closed, and no blood can escape.

Still failing so far, I next proceed to pack the uterus with iodoform gauze by means of the uterine packer, which does not require the use of volsella forceps, but may be guided by a finger into the

uterus. If the hæmorrhage was profuse I would pack the uterus at once after manual compression and the use of ergot had failed to work—packing it completely from fundus to external os.

Having packed the uterus and the hæmorrhage having ceased, the patient should be given plenty of fresh air from open windows to restore the circulation. To prevent fatal impending syncope during the continuance of the bleeding, stimulants, nutrients, and opiates are required.

*Dr. W. P. McIntosh, of Portland, Me., observes:*

The proper way to prevent hæmorrhage after childbirth, or during the third stage of labor, or to arrest it when it occurs, is to cause uterine contraction. Good, firm contraction will prevent post partum hæmorrhage, if, as is generally understood, the blood comes from the uterine sinuses. In some cases, however, the hæmorrhage is from a lacerated cervix or rupture of other soft parts, in which case remedies appropriate to the cause should be applied.

In uterine hæmorrhage, as in all other abnormal or pathological conditions, we have first the cause and then the effect; remove the cause and the effect will cease. To properly get at the cause of a relaxed or flaccid uterus, we must take the case into consideration during the months of pregnancy. Labor at term without disproportion between the canal and the body which has to pass through it (dystocia, maternal or foetal) is generally regarded as a physiological act. Normal labor in itself is a physiological process. But the woman having undergone the strains of pregnancy is not herself, or, rather, her organs are not in a condition to perform their physiological functions in a thoroughly normal manner. The foetal circulation causes an increased pressure in the maternal vessels (as is shown by the sphygmomanometer), and puts an added load upon the heart throughout pregnancy. During the last months of pregnancy the increased weight and size cause difficulty in taking proper exercise, at a time, too, when exercise would aid in the elimination of effete products or toxins. It also throws an additional burden on the respiratory and muscular systems, and these added burdens cause the expenditure of nervous energy. "Should one organ or part of the system flag, an additional load is thrown upon all the others." "When the maternal eliminative system fails to dispose of all of the products of increased metabolism, the resulting toxæmia in itself decreases the efficiency of the muscular system, and through the heart muscles the efficiency of circulation, which latter of itself impairs anew the efficiency of the eliminative organs, and so creates a vicious circle." (Reynolds, *Cæsarean Section*, *Boston Medical and Surgical Journal*.) There is considerable muscular exertion during labor, and this naturally throws more strain upon the heart and nervous system. If the labor is prolonged the woman is exhausted, her muscular endurance is lessened, and with it the contractile power of the uterus, and when its contents are expelled, and there is no longer the irritating or stimulating effects of the child's body to cause contraction, the uterus is likely to become flabby and relaxed, and if the placenta has become partially or wholly detached, leaving the mouth of the vessels

open, a serious hæmorrhage is apt to occur. Violent labor with rapid expulsion of the uterine contents is also likely to cause muscular exhaustion, and as such labors are attended with great pain, nervous coordination and control are lessened, the uterus fails to contract, the mouths of the vessels remain patulous, and hæmorrhage follows.

The causes of post partum hæmorrhage are, therefore, those which interfere with uterine contraction or cause relaxation of the uterine muscles (or laceration of the birth canal). The causes may be systemic, there may be weakness from existing disease, weakness from undeveloped uterine muscular fibres, and fatigue from overstretching, as in twin pregnancies. "Exhaustion from many previous labors or when too suddenly called upon to contract by a rapid labor (especially if instrumental). There may also be mechanical obstacles to firm contraction, as a retained placenta or clots within the womb; old adhesions or a distended bladder may interfere."

To offset to some extent the untoward conditions enumerated, Nature makes certain provisions. In the latter weeks of pregnancy, leucocytes begin to block the uterine sinuses. There is an excess of fibrin making elements in the blood of pregnant women, and this, together with the sluggish blood current in the sinuses, favors the formation of blood clots in orifices of torn vessels. As soon as the uterus is emptied, it contracts so that the blood channels running through the uterine walls are closed by the contracting muscular fibres. "What is thus gained by contraction is held by retraction." In case this does not occur we have hæmorrhage.

*Symptoms.*—Post partum hæmorrhage may occur during the third stage of labor or during the first twenty-four hours thereafter from relaxation of the uterus. It can usually be readily recognized. Of course, when there is a gush of blood, or, as Hirst puts it, "when the blood soaks through the mattress and runs across the floor in a stream," it is easily recognized. But the bleeding should be detected and arrested long before anything of this kind can occur. Usually the first gush of blood is followed in a few seconds by a further flow of fluid blood and clots. It is my usual custom to form my hand into a sort of a cup and hold it at the vaginal outlet. In this way I catch the blood in the hand and at the same time I can feel the warm fluid. The other hand is placed upon the abdomen, and if this hand fails to find the contracted uterus, there is an absence of the croquet ball which represents the contracted uterus and which should fill the hypogastrium. The presence of blood in any quantity is all the symptom that is required in acute hæmorrhage. Later the ordinary constitutional symptoms of hæmorrhage, such as a rapid, feeble pulse, blanched face, dilated pupils, sighing respiration, restlessness, and failing vision may be present.

*Treatment.*—The only rational thing to do is to cause the uterus to contract, close the vessels, and stop the bleeding. My own practice is, as soon as the child is born, to inject a hypodermatic syringe of a good fluidextract of ergot into the woman's thigh. It will cause less pain and prevent any tendency to inflammatory reaction if the ergot be injected deep into the muscles. If I have special reasons to fear hæmorrhage, I inject the ergot as soon as the

presenting part emerges from the vulva, and I place one hand on the anterior abdominal wall and grasp the uterus firmly, the fingers being applied to the posterior uterine wall, the palm to the fundus, and the thumb in front. I then compress, knead, and rub the uterus vigorously. If this does not effect the desired result it is probable that the hæmorrhage is caused by a partially detached placenta. I therefore grasp the uterus very firmly, force it down, and express the placenta by Credé's method. Then, keeping the hand on the fundus, should the hæmorrhage persist, I introduce the other hand into the vagina, grasp the cervix and lower uterine segment with the fingers, and push upward, and at the same time push down on the fundus with hand on the outside (bimanual compression of the uterus). In this way the uterine cavity will be partially obliterated, closing the sinuses and stopping the hæmorrhage. Should this not succeed, pass the hand into the uterine cavity, remove all blood clots or shreds of membrane there, double the hand up into a fist, and press down on it with the hand outside of uterus. While I am doing this the nurse, who has already received instructions and has everything ready, passes me the nozzle of an irrigating syringe. The syringe itself is filled with sterile hot water—that is, water that has been boiled and cooled by the addition of cold sterile water to 130° F. No time is wasted, however, in taking the temperature; water about as hot as the hand can bear comfortably is used. The nozzle of the syringe is introduced into the uterus and the water allowed to flow; this will wash out the clots, and in nearly every instance will cause the uterus to contract firmly and the hæmorrhage to cease.

In several years' service in a maternity hospital, where I delivered hundreds of women, I met with only one or two cases in which this failed to stop the hæmorrhage, and in those cases packing of the uterus was necessary.

Another excellent plan is to saturate a piece of sterile gauze in vinegar, carry it up to the fundus of the uterine cavity, and squeeze it out. Vinegar irritates the uterine muscles to contraction at the same time that it acts as an astringent. I prefer to use the hot water first, as it washes out the cavity and generally stops the flow of blood; if not, the gauze soaked in vinegar can be introduced at once and squeezed. Hot water and vinegar can be obtained in any household, and both are safe and reliable. Should these means fail, I prepare to pack the uterine cavity, and in making these preparations, *without losing any time*, I try two other procedures which often succeed. First, I grasp the cervix with a volsella and forcibly pull the uterus down. This will often stop the flow of blood. Then I either elevate the woman's buttocks with pillows or place the woman in Trendelenburg's position over the back of a chair. The use of pillows is much more convenient and does not interfere with other manipulations. During this time the woman has been lying, by preference, across the bed. The uterus is already drawn down. The nurse is standing at my side with the box of gauze and a long placental forceps. Let the nurse with one hand grasp the volsella and place the other hand on the fundus uteri. This gives the operator the use of both hands. Or it may be better, if only one assistant is available, to allow

the handles of the volsella to hang down, and thus by their weight assist in holding the uterus down. This allows the nurse to hold the box of gauze near the vulva. The operator passes the fingers of his left hand into the cervix, and, having grasped one end of the piece of gauze in the forceps, proceeds to pack the whole uterine cavity firmly from the fundus down. This absolutely stops the bleeding, but the external pressure must be kept up for a time by the hand upon the abdomen.

Before leaving this subject I wish to say something more in regard to the placenta. In cases of retained placenta, or those which cannot be expressed by Credé's method, I introduce my hand into the vagina, pass it into the uterine cavity, slip the fingers under the edge of the placenta, and by a to and fro movement of the fingers gradually peel the placenta off; at the same time the hand on the outside of the uterus, on abdominal wall, is holding the organ firmly, and as soon as the afterbirth is detached the uterus is tightly squeezed and forced down and the placenta is expelled.

It is not well to hurry the third stage of labor in every case; generally fifteen or twenty minutes should be allowed to elapse before the placenta is expressed. But in case of hæmorrhage it is necessary to empty the uterus in order to get contraction. Therefore, one cannot wait. Besides, the placenta is partially detached or there would be no hæmorrhage.

I do not regard use of the stronger chemicals, such as Monsel's solution, iodine, or oil of turpentine, as ever justifiable, used inside of the uterus, and, furthermore, they are not necessary, as packing the uterus in severe cases of hæmorrhage stops the blood and is cleanly. There is no objection to the use of the faradic current, though the same is seldom available, and I have found it of little use. If the woman has lost much blood I always give 1,000 c.c. normal salt solution by hypodermoclysis. This is to be given only after the hæmorrhage is under control, but should never be omitted, for the acute anæmia following hæmorrhage is often as dangerous to life as a continuance of the hæmorrhage. And, as I have shown elsewhere (*New York Medical Journal*, June 10, 1905, p. 1147), the use of the saline solution by hypodermoclysis causes a decided increase in both the erythrocytes and the leucocytes, or, in other words, it causes a rapid increase in the solid constituents of the blood, while it largely takes the place of serum itself. It is therefore rational to replace the blood in as rapid a manner as possible, as, aside from the acute anæmia, a woman who has suffered from a serious depletion of the system is in the worst possible condition to resist the incursion of disease.

The salt solution should be given warm and may be given by intravenous injection or injected into the loose cellular tissue under the breasts or between the shoulders. It is not alone for desperate cases that I use this remedy, but in any case where there has been any considerable loss of blood. I also repeat it once or twice during the first forty-eight hours. An aspirating needle, a piece of rubber tubing, and a small funnel are all the apparatus needed, or, as I often do, fix the needle on the rubber tubing of an irrigating syringe. A teaspoonful—about 50

grains—of salt to a quart of warm sterile water, and all is ready. The needle should be in every obstetrical case along with irrigator or tube, and should be boiled when other instruments, such as scissors, needles, etc., are boiled.

A hypodermatic injection of strychnine is also given at once. This stimulates the whole muscular system through the spinal cord; 1,000 c.c. hot salt solution may be given by the rectum also, and hot bottles placed around the patient's body. While these things have been going on, either the nurse or the obstetrician has given attention to the uterus, keeping one hand on the abdomen and a clean napkin over the vulva, in order that any relaxation of the uterus may be prevented. However, the ergot is having effect by this time, and the packing, if it has been used, prevents any further hæmorrhage. Then a large abdominal pad should be laid above the umbilicus and a snug abdominal binder applied. The nurse should be instructed to feel occasionally to see that the uterus remains firm and contracted, also to count the pulse and to occasionally look and see if any hæmorrhage is taking place.

"Laceration of the cervix may cause hæmorrhage after delivery, and occasionally dangerous bleeding may occur from this cause. The diagnosis may be made by a careful digital examination of the vagina and cervix immediately after the expression of the placenta." The hæmorrhage may be arrested either by ligation or tampon. The readiest and safest way is to pack the lateral vault of the vagina with iodoform gauze. This, inserted in form of a half ring, will always control hæmorrhage from a torn cervix. After forty-eight hours the cervix should be properly repaired. Lacerations of the vulva, of the vestibule, and of the vaginal entrance may occur. In this case the hæmorrhage is in plain sight and can be easily controlled by ligation and sutures. Lacerations of the perinæum should be sutured at once. All that is needed is a curved needle and some silk-worm gut. Both should be boiled and be ready in case of need.

*Dr. C. L. Sigler, of Pinckney, Mich., states:*

A description of the treatment of puerperal hæmorrhage would not be complete without mentioning preventive measures, and this cannot be done without a word as to the ætiology, which, in general, may be said to consist of either imperfect contraction of the uterus, retention of part of the secundines, lacerations, or hemophilia.

I have found it a wise plan to follow down the uterus with one hand as the child is expelled, assisting contractions with friction or pressure over fundus if necessary. After the expulsion of the child the uterus is first seen to be contracted firmly on the placenta, then the cord is tied.

I do not immediately express the placenta, but unless contractions soon follow the birth of the child I administer a full dose of some reliable fluid-extract of ergot, and then if expulsive contractions do not supervene in fifteen or twenty minutes the uterus is stimulated by friction over the epigastrium or gently kneading the uterus. As it is felt to contract under the hand, pressure is made, and the placenta is usually expelled without other assistance. After the expulsion of the placenta the

uterus is assisted to contract, if necessary, by gentle manipulation through the abdominal wall.

At no time from the birth of the child until the uterus is seen to be firmly and permanently contracted after the birth of the placenta does my hand leave the abdomen for more than a minute or two at a time. Too rapid emptying of the uterus is apt to be followed by poor contractions and hæmorrhage, as after instrumental delivery or removal of placenta by traction. An atonic condition of the uterine wall may also follow prolonged labor, especially when chloroform has been used through the third stage. In case of the actual occurrence of postpartum hæmorrhage, an examination should be immediately made to ascertain whether the uterus is well contracted, and to obtain this result we always have means which, in the great majority of cases, is efficient, namely, manipulation of the uterus either through the abdominal wall or bimanually. If contraction does not follow, or if the contraction does not control the hæmorrhage, the interior of the uterus should be explored to ascertain the presence of clots or placental fragments.

If these are present they should be brought away by the examining finger, the fingers of the other hand at the same time grasping the uterus through the abdomen. While some good hypodermatic preparation of ergot should be immediately given in these cases, no time should be lost in waiting for it to act, as time is precious.

Ice is usually obtainable in most households, and when applied to the epigastrium or a fragment introduced into the uterus, contraction usually follows.

Hot sterile water, which should invariably be at hand, may be introduced into the uterus through the nozzle of an ordinary syringe. If used as hot as can be borne by the back of the hand it will usually stimulate contraction.

Vinegar may be introduced by the same means, or squeezed from a wad of gauze or pledget of cotton, or, as I prefer, a 2 per cent. solution of acetic acid, a small bottle of which should be found in the obstetrical kit, as should either a Davidson or fountain syringe. If necessary to temporarily control the hæmorrhage while an assistant is preparing the solutions or other material, the cervix may be grasped through the vagina with one hand, while the other grasps the fundus, which can generally be easily done between the separated recti. By now approximating the two hands, bringing the fundus downward and forward, the cavity of the uterus is mechanically obliterated, and the hæmorrhage temporarily stopped.

The vagina should never be tamponed for post partum hæmorrhage, but when other measures fail the uterus may be packed with iodoform or salicylated gauze.

The small gauze packers are entirely too small for this purpose, and it may be best done by pulling down a lip of the cervix with a volsella and applying the gauze with a long uterine forceps. This procedure will need be resorted to but rarely, as the other measures mentioned will almost invariably be successful.

If the blood is found to come from a lacerated cervix or perinæum, appropriate surgical measures should, of course, be promptly instituted.

*Dr. St. Clair-Jones, of Jersey City, N. J., says:*

Post partum hæmorrhage is generally the sequel of a long and tedious labor.

There is no condition more alarming and, indeed, more often fatal to the puerperal woman, at the same time taxing the energy and the practical resources of the experienced physician, to say nothing of the juvenile.

Occurring as it does toward the end of the third stage of labor, a period which is usually considered as the end of the woman's pains and trials, everything having hitherto progressed favorably, but often it proves to be the turning point of imminent and unforeseen danger.

Post partum hæmorrhage offers one of the best opportunities of making or marring a reputation.

Treatment resolves itself into prophylactic and actual.

In the first place, too much care and precaution cannot be exercised in the earlier stages of labor. Discretion must be used in promoting or retarding labor, as occasion should arise. Whenever possible nature should be allowed to take its course; rapid delivery is very reprehensible, and in itself is inductive to uterine inertia and atony, with its sequelæ, especially in women with Bright's disease and other constitutional dyscrasia.

I have seen the pernicious habit practised by physicians, everything being normal and favorable, of "hurrying up labor," i. e., of dilating the partly dilated os, rupturing the membranes, and delivering under anæsthesia. Such a habit cannot be too strongly denounced.

Inspection of the vagina and cervix for lacerations, which, if present, should be immediately repaired, is the first step, to be followed by removal of all clots, which act as a mechanical obstruction.

It is of paramount importance that there should exist an efficient and proper contraction of the uterus after delivery of the placenta. It is Nature's safeguard. Hence fluidextract of ergot,  $\mathfrak{z}$ i every hour, the removal of the pillow, and Credé for one half to one hour until proper contraction occurs.

In multiparæ, obtaining a history of previous labors will serve to prepare one for the emergency should hæmorrhage usually exist.

The early application of the child to the breast serves the twofold purpose of promoting uterine contraction by reflex action and at the same time the colostrum acts on the child's bowels.

Lastly, the proper application of an abdominal binder.

In the actual presence of the contingency, all practical resources must be brought to bear promptly and decisively.

Credé's method, previously referred to, must be vigorously applied, in addition to manual pressure on the fundus and attempting to grasp the flaccid organ laterally.

An intravaginal examination should at once be made to ascertain the existing condition, for, apart from the removal of any existing blood clots, the hand acts as a stimulus to the cervix, promoting contraction. If the os is wide and patulous, pass the hand within the uterus.

Combined manipulation by introducing one hand with a lump of ice into the vagina, sometimes the rectum, as far as Douglas's cul-de-sac, having the thighs flexed on the abdomen, and make strong pressure with the other hand on the uterus. More often, however, better results are obtained by alternating with hot water, the nozzle of the syringe being carried into the uterus. Give a hypodermatic injection of ergot,  $\mathcal{M}$  30 to 60, into the nates, repeated if necessary.

The intrauterine application of vinegar, or the squeezing of lemon juice, often proves beneficial.

Syncope must be guarded against; give strychnine sulphate; I prefer the nitrate, up to gr. 1/30, every hour, with whiskey by mouth, meanwhile elevating the pelvis, lowering the head, and applying hot water bottles to the feet. Hypodermoclysis, one quart of a normal salt solution. Cotarine hydrochlorate, gr.  $\frac{3}{4}$ , given hypodermatically, repeated every two or three hours, often proves serviceable, producing decided stypitic effects with none of the evils of opium. Tamponing with sterile gauze is also of service, but great precaution must be taken lest an external hæmorrhage be converted to an internal.

The patient at all times should receive the benefit of every known remedy; especially is this true in cases which seem hopeless and desperate. Hence pressure on the aorta can be practised, but whether productive of great benefit is doubtful, since the great volume of blood undoubtedly issues from the dilated uterine sinuses.

The stypitic salts of iron are attended with too much danger to justify their use, except as a last resort, all others having failed.

Transfusion of blood in those delicate women who afterward suffer a protracted convalescence is advised.

After treatment.—Absolute quiet and rest in the recumbent position. Precautions must still be taken against any recurrence of hæmorrhage. The depleted system must be aided by good, nutritious, and easily assimilated diet, gradually introducing stimulants, good port wine, and tonics, with hygienic surroundings.

(To be continued.)

### Correspondence.

#### LETTER FROM KINGSTON, ONTARIO.

*The Medical Laboratory Building of Queen's University.*

KINGSTON, January 20, 1908.

The new medical laboratories building of Queen's University was dedicated on the afternoon of January 14th. The ceremonies were held in the old Convocation Hall, and there were present for the event, among others, the Hon. Dr. R. A. Pyne, Minister of Education of Ontario, and formerly registrar of the Ontario College of Physicians and Surgeons; Dr. L. F. Barker, of Johns Hopkins University, Baltimore; Dean Reeve and Professor A. B. MacCallum, of Toronto University medical faculty, and Professors Wesley Mills and J. George Adams, of McGill University, Montreal. There was a large audience in attendance. The presence of representa-

tives from Toronto and McGill implied that the three universities were on terms of cordiality, which should ever be. Dean Connell made a statement regarding the history of Queen's medical department, which was established in 1854, and amid an imposing silence he called the roll of the departed members of the medical profession of Kingston by whose self sacrifice and devotion Queen's medical department had been able to exist. The dean commended the Ontario government for its wisdom in adopting the principle of State aid for medical education. In the new building will be accommodated histology, physiology, pathology, biology, and bacteriology. There will also be rooms for public health work, which has grown in a few years to be a considerable tax upon Queen's resources. During the past year 1,505 examinations have been made free of expense to the public, and specimens have come all the way from Fort William to Ottawa. Dr. Barker, the eminent Canadian, who succeeded Dr. William Osler at Johns Hopkins University, delivered an admirable address upon medical laboratories and their relation to medical research and discovery, and emphasized the fact that Canada owed the duty to science of seeing that its brightest medical students were given encouragement to take up research work for the benefit of generations to come.

The Hon. Dr. Pyne, Minister of Education, congratulated the medical faculty upon its fine new building. He scarcely knew how they had managed to erect such a magnificent stone edifice for less than \$50,000. He would inform Premier Whitney that he had never seen \$50,000 so well expended. Government aid, he said, for research work was money that could not be better spent. He assured Queen's medical faculty that it would in future have the sympathy of the government. Short addresses were also made by Dean Reeve and Professor MacCallum, F. R. S., Toronto University, as well as by Professors Adams and Mills, of McGill University, all congratulating Queen's on its advances and the work it was doing for medical science.

### --- Therapeutical Notes. ---

**Medicinal Uses of the Mistletoe.**—In olden times many virtues were ascribed to the mistletoe (*Viscum album*), it being regarded as a sacred plant. In France it is coming into use again, and several pharmaceutical preparations of it have been introduced into medicine, some under proprietary names. It is understood to be a component ingredient in a certain proprietary remedy for epilepsy. An English practitioner recommends its use in chorea. According to *The Prescriber* for January, 1908, the berries are emetic and purgative. The plant has also an ancient reputation as a cure for postpartum hæmorrhage, a property which has been more than once confirmed within recent years. Quite lately its composition and action have been investigated on the Continent, where Gaultier, in a communication to the French Society of Therapeutics, has shown it to possess the property of diminishing arterial pressure. Plants growing on the poplar and plum have been found most active, and from these several phar-

maceutical preparations have been made, including an aqueous extract, a syrup made therefrom, and a "physiological solution" for hypodermatic and intravenous injection. This last is prepared by infusing the leaves in normal saline solution and sterilizing.

**Applications for Chilblains.**—*The Prescriber* gives two useful prescriptions for the alleviation of the painful symptoms accompanying chilblains:

## I.

To form a protective skin on the surface of the chilblain apply the following:

R	Tannic acid, . . . . .	3ii;
	Alcohol, . . . . .	3iv;
	Carbolic acid, . . . . .	℥xxiv;
	Water, enough to make, . . . . .	3i.

Solve. Sig.: Paint on the chilblains night and morning.

## II.

The application of a cream of the following composition acts as an agreeable and efficient stimulant to the circulation:

R	Menthol, . . . . .	gr. xv;
	Methyl salicylate, . . . . .	3ii;
	Hydrous wool fat, . . . . .	3vi.

M. Sig.: Apply a small quantity frequently, rubbing in until absorbed.

**Potassium Permanganate as a Styptic.**—Dzirme (*Vratchebnaya Gazeta* and *The Prescriber*) has succeeded in checking capillary oozing in operating on parenchymatous organs by applying to the orifice of the bleeding vessel a small crystal of potassium permanganate held with forceps. If there is general oozing from the surface he recommends making pressure with a compress of gauze dipped in crystals of permanganate. At the point of contact an eschar is formed upon the wounded surface, and the bleeding stops. The crystals are preferred to the powdered permanganate, because a smaller quantity can be used to produce the desired effect. The author has never observed any injurious effect from the permanganate.

**Depilatory Pastes.**—An efficient substitute for the use of the razor in the removal of hairs from any part of the body, before operation, is recommended by Bilout, of the French army, who publishes the formula in the *Archives de médecine militaire*, from which it is cited by *The Practitioner*, for January, 1908, as follows:

R	Sodium monosulphide, . . . . .	1 part;
	Lime (unslaked), . . . . .	1 part;
	Powdered starch, . . . . .	2 parts;
	Sufficient water to make a paste.	

## M.

The lime and the sodium monosulphide must be finely powdered in separate mortars. The monosulphide is then well mixed with the starch, and with this the lime is carefully mixed up. Water is then added in just sufficient quantity to form a soft paste, neither a fluid, which is inert and useless, nor a grumous powder, which cannot be applied. The area which is to form the field of operation is well washed with soap and a brush in plenty of hot water, and all the longer hairs are clipped with scissors. The paste, freshly made, is then applied with a bone spatula over the area to a thickness of rather less than one-tenth of an inch. After waiting for five

minutes, and making sure that all the hairs are detached, the layer of paste is easily removed with a sterile swab and a small jet of boiled water. The surface is left completely denuded of hairs, and particular care must be taken to avoid leaving any of the paste behind, as it will set up a secondary caustic action. The area is then kept covered with a sterilized dressing until the operation begins.

In the New York City hospitals barium sulphide is preferred to sodium sulphide as in the following formulas, which are taken from *The Hospital Formulary of the Department of Public Charities*:

## I.

R	Barium sulphide, . . . . .	3 parts;
	Corn starch, . . . . .	1 part;
	Water, . . . . .	q. s.

## M.

## II.

R	Barium sulphide, . . . . .	25 parts;
	Powdered soap, . . . . .	5 parts;
	Powdered talc, . . . . .	35 parts;
	Corn starch, . . . . .	35 parts;
	Water, . . . . .	q. s.

## M.

**Method of application:** Make one teaspoonful of the powder into a paste with three teaspoonfuls of water, and apply to the parts with an ordinary shaving brush in a moderately thick and even layer. After four or five minutes the parts should be moistened with a wet sponge, when after another five minutes, the hair can be removed by washing off the mass.

**Note.**—The barium sulphide must be as fresh as possible and not have become oxidized by exposure to the air.

**Lotions for Intertrigo.**—Sabouraud (*La Quinzaine thérapeutique*) prescribes the following:

## I.

R	Tincture of iodine, freshly prepared, . . . . .	3iiss;
	Eau de Cologne, . . . . .	3vi.

## M.

## II.

R	Alkaline solution of tar, . . . . .	3iv;
	Eau de Cologne, . . . . .	3vss.

## M.

## III.

R	Ichthyol, . . . . .	3iiss;
	Distilled water, . . . . .	3iii.

## M.

**Douche in Leucorrhœa.**—An excellent douche in cases of leucorrhœa, according to *The Hospital*, is composed of a solution of quinine hydrochloride in warm boric acid solution, in the proportion of one grain of the salt to one ounce of the warm saturated solution of boric acid. The salt may also be prescribed in the form of glycogelatin pessaries, two or three grains in each.

**Treatment of Intestinal Flatulence.**—In the *Southern California Practitioner*, Dudley Felton describes the treatment adopted by Cohnheim, of Berlin. Menthol is considered the most effective medication and is prescribed in the following combination:

R	Tincture of belladonna leaves, . . . . .	3i;
	Spirit of peppermint, . . . . .	3i to 3ii;
	Tincture of valerian, . . . . .	3ss.

M. et sig.: Thirty drops in water, three times a day, after meals.

NEW YORK, SATURDAY, JANUARY 25, 1908.

## THE MILK QUESTION IN CHICAGO.

As we said some months ago, it is not New York alone, but every large city as well, that is vitally interested in the question of the quality of its milk supply. The matter has recently met with unusual attention in Chicago, apropos of a committee's report to the Chicago Medical Society. So far as we have been able to ascertain, not a single Chicago physician has sought to perpetuate the delusion that pasteurization is a trustworthy safeguard of the quality of a milk supply. That is more than can be said for the profession of some of our other cities. Pasteurization is at best a makeshift, for it only works some temporary improvement of bad milk, leaving even such milk less nutritious than it was to begin with and disposing it to changes that still further impair its value as an article of food for adults and as the staple aliment for infants.

The discussion in Chicago seems to have turned largely upon the apparent unwillingness of the people to pay a slightly increased price for pure milk that has been properly handled and promptly delivered in good condition. The blame has been attributed to a very great extent to the thrifty housewife, who is said to regard the exaction of an enhanced price as "robbery." We doubt if this is quite fair; it is generally the father of the household who pays the bills and does the grumbling. However this may be, we have no reason to believe that the people of Chicago will not cheerfully pay well for good milk when they are really convinced that the more expensive article is substantially superior to

the product with which they have heretofore been content. Certainly they will not be willing to endanger the health and lives of their children for the sake of saving a cent or more on a quart of milk. Our brethren of Chicago are assuredly doing effective work in bringing their fellow citizens to a realization of the fact that a good article costs more than a poor one.

It is interesting, but quite in accord with common observation, to remark that it is the wealthy who are particularly charged with parsimony in this matter of milk. The rich woman, it is said, will soundly berate her milkman for an advance from seven to eight cents a quart, and then betake herself to a fashionable club, where she will unhesitatingly pay ten dollars for a luncheon. Perhaps, however, it is the satisfaction that she takes in the denunciation itself, rather than real stinginess, that prompts her, for the domineering spirit which so soon takes possession of the rich finds less resistance among the humble than among those who are but a few rounds of the ladder lower than the one who does the scolding. But doubtless the wealthy will insist on having the best of milk, and they will certainly have to pay for it.

SUNLIGHT AND THE TUBERCLE  
BACILLUS.

There has recently been published in pamphlet form an important paper, by M. Paul Juillerat and Dr. Alfred Fillassier, dealing with the hygienic conditions found on inspection of the dwellings in certain quarters of Paris in which there has been a large mortality from tuberculous disease. The paper was presented before the Fourteenth International Congress of Hygiene and Demography, held in Berlin in 1907. The authors lay great stress upon the defective arrangements in these dwellings for exposure of the rooms to the light of day, and we cannot doubt that they are warranted in so doing.

During the year 1906 the inspectors visited 405 new houses, comprising 20,467 suites, consisting of 43,621 rooms, inhabited by 47,130 persons, an average of 1.08 to each room. This density of population the authors do not regard as excessive. Since January 1, 1894, these houses had shown a mean annual mortality from tuberculous disease of seven to each thousand inhabitants. It was found that 3,616 sleeping rooms were practically without air and light, sixty-three air shafts being so small as to be absolutely inadequate to the ventilation and lighting of the rooms opening on them. The proportion of dark rooms was found to be enormous, rooms into which the sunlight never penetrated. They were choice places for the lodgment and pre-

servation of Koch's bacillus and the almost inevitable infection of succeeding tenants.

But the municipality has set on foot measures for the methodical sanitation of these dark houses, and the authors are confident that in a few years, when these murderous rooms have been made to disappear, an improvement will be seen in the tuberculous mortality returns. They have concluded from the totality of their observations that tuberculous disease is the disease of darkness. Once introduced into dark rooms, Koch's bacillus propagates itself and maintains an extreme virulence.

It is not to urban apartment houses alone that we may apply the lesson to be drawn from these observations; many a room that the good rustic housewife carefully darkens, lest it should become a trifle warm, or troublesome insects should be admitted, or the carpet should grow faded, ought to be laid bare to fresh air and sunlight if it is ever to be occupied by a human being. It is in darkness and in stagnant air that noisome germs luxuriate; flush them with fresh air and the direct rays of the sun, and we go far toward robbing them of their maleficent power. If the "best room" of a farmhouse were systematically and persistently flooded with fresh air and sunlight, instead of being kept in sepulchral stateliness, the family and their visitors would reap the reward of vastly increased stability of health.

#### COMPULSORY SURGICAL OPERATIONS.

We ruthlessly cut out the testicles of the unconsenting bull and stallion, we dock horses' tails, and we practise other mutilations of the domestic animals. These cruelties we perpetrate for purposes of our own, and nobody calls a halt. Animated by nobler motives, we subject young children to various surgical procedures, and hardly anybody objects. But it is difficult to conceive that any person, apart from the dreamers who hope to regenerate the human race by castrating criminals, should think of decreeing and carrying out an operation on any sane adult individual of our species in defiance of his or her opposition. It seems, however, that such a notion has been broached in the United Kingdom. It is an outgrowth of the restiveness with which the new workmen's compensation law is submitted to.

The question has come up in court, as we learn, from the *British Medical Journal* for January 11th. It does not appear that any British court has yet ordered a man to be operated on against his will, for such a course is not held to be warranted by the law; but it seems that the courts have the power, and in some instances have exercised it, of reducing to a nominal amount the compensation due under the law in cases in which the pensioners refuse to sub-

mit to an operation fraught with but infinitesimal danger and holding out the prospect of substantial repair of a disability resulting from injuries incidental to their work.

There can, we think, be no question of the equity of such a procedure, whatever may be the final judicial ruling. As human nature is constituted, there will probably always be many persons who will choose a life of indolence under pay rather than resort to rational means for regaining their legitimate earning power. Surely there ought to be some way of curbing this manifestation of parasitism. We may say that the law under which it is possible ought never to have been enacted. We do say so. But there the law is, a piece of iniquitous class legislation. If its tyranny can be mitigated only by resorting to an apparent subterfuge, by all means let the recourse be had.

Apart from any question of the competency of a court to compel a man to submit to a surgical operation against his will, it may well be doubted if any self respecting surgeon would be willing to carry out such a behest. When we feel that a procedure repugnant to a patient is manifestly almost sure to prove advantageous to him, we urge it upon him with all our powers of persuasion, but we never proceed to execute it *vi et armis*. In the practice of medicine compulsion is out of place.

#### THE SERUM TREATMENT OF EPIDEMIC CEREBROSPINAL MENINGITIS.

We have already noticed Flexner's preliminary experiments carried out for the production of a curative antiserum for *Diplococcus intracellularis* infection (*New York Medical Journal*, May 11, 1907). The serum has since been prepared on a large scale and has been used in cases of epidemic cerebrospinal meningitis by Dr. W. S. Chase, in eleven cases, in Akron, Ohio; by Dr. L. W. Ladd, in sixteen cases, in Cleveland; by Dr. W. T. Longcope, in five cases, in Philadelphia; by Dr. Cushing, in one case, in Baltimore, and by Dr. Strain, in three cases, in New York. The serum has also been used in Edinburgh and in Belfast for the treatment of cases of cerebrospinal meningitis.

The results of these trials of serum therapy in this serious disease have been collected by Flexner and Jobling and are published in the *Journal of Experimental Medicine*, x, 1. Of the thirty-six patients treated in the United States, twenty-six, or 72.22 per cent., recovered, and ten, or 27.77 per cent., died. We leave out of consideration in this review the nature of the cases, the length of time after the onset of the disease that the injection was given, whether the case terminated by lysis or by crisis, etc., although all these facts influence one's judgment of

the value of the agent. But if a treatment can show a recovery rate of over 70 per cent. of cases irrespective of severity and of the duration of the infection, in a disease in which, by other methods of treatment, the recoveries form from 20 to 75 per cent. of the cases, depending upon the severity of the epidemic, surely it is worthy of serious consideration and of careful and extended trial.

This serum is injected directly into the subarachnoid space after the withdrawal of cerebrospinal fluid by means of lumbar puncture. The quantity injected should not at present exceed thirty cubic centimetres. It seems desirable to withdraw an amount of fluid equal to that to be injected; the injection should be made slowly and carefully, and the serum should be warmed before it is injected. Until it is wanted for use, it should be kept in the refrigerator. The injection should be repeated daily for three or four days. As in all diseases in which serum treatment is applicable, the earlier the treatment is begun the better will be the results. The reasons for this should now be so obvious to physicians that we deem it unnecessary to repeat them here.

#### THE TRANSMISSIBILITY AND HEREDITY OF MALIGNANT TUMORS.

While many observers believe that malignant tumors may be transmitted naturally from animal to animal or from man to man, the failure of many inoculation experiments to result in the growth of the transplanted tumor has given rise to well founded skepticism concerning the transmissibility of such growths in general. Other writers have maintained that malignant tumors are hereditary, and that a tendency to their production is handed down from parent to offspring. On the other hand, there are many instances in which no evidence of heredity can be obtained, in spite of diligent search.

From a study of the inoculability of tumors, Loeb and Leopold (*Journal of Medical Research*, December) conclude that tumors differ as to whether they are transplantable or nontransplantable, as to whether they are transitory or permanent in their growth, as to whether they grow rapidly or slowly, as to whether they are infiltrating or circumscribed, and as to whether or not they give rise to metastasis. The lymphosarcoma of dogs, according to these authors, possesses the widest range of inoculability, as it can be transplanted into other members of the family *Canis*. The sarcoma of white rats and the adenocarcinoma of white mice can be transplanted into animals of the same species, but not readily into those of other species or into by-

brids. The adenocarcinoma found in the Japanese mouse cannot be transplanted into other species. Other tumors, and they form the largest class, cannot be inoculated even into other animals of the same species. The majority of human tumors are uninoculable.

McConnell, however, has recently succeeded in inoculating an adult white rat with a piece of a human scirrhus carcinoma of the breast. The tumor did not grow, but became encapsulated and showed degenerative changes when examined five months later. A piece of the same tumor transplanted at the same time into a white rat about four weeks old was entirely absorbed (*Journal of Experimental Medicine*, January). As the result of a series of experiments on mice to determine the influence of heredity on the inoculability of tumors, Tyzzer (*Journal of Medical Research*, November) concludes that, though the breeding has not been sufficiently extensive to prove or disprove the influence of an inherited character on the development of malignant tumors, the data so far available appear to favor the view that there is such an influence.

#### SPONTANEOUS TUMORS IN MICE.

There are many reports on record of the occurrence of spontaneous carcinomata in mice, as well as in other animals. The original successful transplantation was made by Hanau, who, in 1889, succeeded in inoculating a carcinoma of a rat into other rats. The active work in inoculating healthy animals with pieces of tumors from other animals of the same species gives new interest to the reports of malignant tumors in all animals. It is possible that some of these tumors will be found to give better results than those already experimented with for propagation. Tyzzer (*Journal of Medical Research*, November) reports sixteen new cases of spontaneous malignant tumors in mice, giving the details of their histology. In this series there are nine cases of papillary cystic adenoma of the lung, one case of cystic adenoma of the kidney, two cases of lymphosarcoma, one in the inguinal region and one in the mediastinum, and four subcutaneous adenocarcinomata. As regards the four subcutaneous adenocarcinomata, two of the animals had additional primary tumors in their lungs; in one the primary subcutaneous growth was in the mammary gland and in the other it was in the inguinal region. Six of the tumors of this series were inoculated into fifty-four normal mice with four positive results: two each from two specimens of subcutaneous adenocarcinoma.

## News Items.

**Changes of Address.**—Dr. Charles K. Stillman, to 119 East Twenty-seventh street, New York.

**The California State Board of Medical Examiners** will hold its next examination in San Francisco on April 7th.

**The Vienna Academy of Sciences** has made an appropriation of \$300 to Dr. Robert Falta for his work on diabetes.

**Kingston, N. Y., Board of Health.**—At a recent meeting of this board, Dr. Leonard K. Stelle was appointed health officer of Kingston, to succeed Dr. J. T. Buckley, who has resigned.

**A Vaccination Bureau in Kingston, N. Y.**—A free vaccination bureau has been established in Kingston, N. Y., and Dr. Frank Keator and Dr. Elbert D. B. Loughran have been placed in charge.

**Health of the Philippine Islands.**—According to the report of Dr. Victor G. Heiser, Director of Health, health conditions in the Philippines are improving, the population is increasing, and the rate of mortality is steadily declining.

**The North St. Louis, Mo., Medical Society** has elected the following officers to serve for the year 1908: Dr. H. J. C. Sieving, president; Dr. A. A. Henske, vice president; Dr. H. J. Niebruegge, secretary; and Dr. A. F. Koetter, treasurer.

**The Buffalo Medical Clinic** held its regular monthly meeting on Thursday evening, January 9th, at the residence of Dr. Edward L. Frost. The paper of the evening, entitled Complications of the Menopause, was read by Dr. John Chalmers.

**The Sixteenth International Medical Congress.**—Dr. William P. Spratling, medical superintendent of the Craig Colony for Epileptics, Sonyea, N. Y., has been named as chairman of a Section in the Public Care of Epileptics at this congress, which will meet in Budapest on August 29 to September 4, 1908.

**The West Philadelphia Medical Association.**—The new officers of this association for the year 1908 are as follows: President, Dr. Henry D. Jump; vice president, Dr. Arthur Bogart; recording secretary, Dr. George Mills Boyd; financial secretary, Dr. Charles E. Price; and treasurer, Dr. Edmund L. Graf.

**The Obstetrical Society of Philadelphia.**—At the January meeting of this society the following officers were elected for the ensuing year: President, Dr. James M. Baldy; vice presidents, Dr. Daniel Longaker and Dr. George M. Boyd; secretary, Dr. Frank C. Hammond; and treasurer, Dr. J. W. West.

**The Franklin District, Mass., Medical Society** held its regular meeting in Greenfield, Mass., on January 14th. Sudden Deaths from Natural Causes in Medicolegal Work was the title of a paper read by Dr. Francis J. Canedy, of Shelburne Falls, and a paper on Erysipelas was read by Dr. A. L. Newton, of Northfield.

**Infectious Diseases in Chicago.**—During the week ending January 11th the following cases of infectious diseases were reported to the Department of Health: Diphtheria, 92 cases; scarlet fever, 102 cases; measles, 51 cases; chickenpox, 35 cases; typhoid fever, 22 cases; whooping cough, 16 cases; tuberculosis, 35 cases.

**The Society for the Destruction of Vermin** is the name of a society recently organized in London. The object of this society is to bring about a general crusade against rats wherever found, on the ground that these animals are dangerous to the public health, and also injurious to many agricultural and commercial interests.

**The New Haven, Conn., Medical Association** held its annual meeting on Wednesday, January 15th, and elected the following officers for the ensuing year: President, Dr. Edward M. McCabe; first vice president, Dr. A. N. Alling; second vice president, Dr. Merriman H. Steele; secretary, Dr. E. Reed Whittemore; treasurer, Dr. Robert E. Peck.

**The Hartford, Conn., Medical Society.**—The annual meeting of the Surgical Section of this society will be held on Monday, January 27th. After the election of officers for the ensuing year a paper on Surgery of the Knee-

joint will be read by Dr. J. E. Root, and a paper on Surgery of the Anklejoint and Foot will be read by Dr. P. D. Bunce.

**Medical Association of the Greater City of New York.**—At the annual meeting, held on Monday evening, January 20th, the following officers were elected: President, Dr. Robert T. Morris; corresponding secretary, Dr. Frank C. Raynor; treasurer, Dr. A. Ernest Gallant; and chairman for the Borough of Brooklyn, Dr. J. Scott Wood.

**The New Contagion Hospital in Kingston, N. Y.,** is well equipped, and is temporarily under the charge of Miss Bratton, the directress of nurses at the Benedictine Sanitarium, the Sisters very kindly coming to the relief of the city during the recent smallpox epidemic. Conditions are beginning to improve under strict quarantine regulations.

**The Harvey Society Lectures.**—The fifth lecture in the Harvey Society course will be delivered by Professor George W. Crile, of the Western Reserve University, Cleveland, Ohio, at the New York Academy of Medicine on Saturday, January 25th, at 8:30 p. m. The subject is Shock. All interested are cordially invited to be present.

**The Lewis County, N. Y., Medical Society** held its annual meeting in Lowville on Tuesday, January 14th, and elected the following officers for the ensuing year: President, Dr. F. E. Jones, of Beaver Falls; vice president, Dr. O. G. Harrington, of Constableville; secretary, Dr. H. A. Pawling, of Lowville; and treasurer, Dr. I. D. Spencer, of Croghan.

**Medical Society of Troy and Vicinity.**—At the annual meeting of this society, held in Troy, N. Y., recently, the following officers were elected: President, Dr. Hiram Elliott, of Troy; vice president, Dr. A. Y. Myers, of Buskirk; secretary and treasurer, Dr. William Kirk, Jr., of Troy. Papers were read by Dr. R. H. Irish, of Troy; Dr. Holmes C. Jackson, of Albany, and Dr. J. F. Humphrey, of Saratoga Springs.

**The Pathological Society of Philadelphia.**—At a meeting of this society, held on Thursday, January 23d, the following papers were read: Interpretation of the Appearances Seen in a Peripheral Nerve, by Dr. H. H. Donaldson; The Diagnosis of Diphtheria by Means of Stained Smears, by Dr. E. Burville-Holmes; A Study in Vitro of Liver Necrosis Produced by Intravenous Injection of Ether, by Dr. Leo Leob and Dr. M. K. Meyers.

**The Hospital Conference of the City of New York.**—The next regular meeting will be held on Wednesday, January 29th, at 8:15 p. m., at the New York Academy of Medicine. The Hospital Committee of the State Charities Aid Association will present for endorsement the report on the future hospital needs of Greater New York, and this will be followed by a general discussion of the subject of Experiences in the Purchase of Food Supplies.

**Philadelphia County Medical Society.**—The Central Branch of this society held a meeting on Wednesday, January 22d. Papers were read as follows: Wanted—A Medical Bureau of Publicity, by Dr. J. Madison Taylor; The Importance of an Ocular Examination in Pregnant Women Manifesting Constitutional Signs of Toxæmia, by Dr. William C. Posey and Dr. John C. Hirst; Gastroenterostomy in Cancer of the Stomach, by Dr. John J. Gilbride.

**Syracuse, N. Y., Academy of Medicine.**—The regular meeting of this academy was held on Tuesday evening, January 21st, when the following programme was presented: Dr. J. R. Johnson reported two cases, one of typhoid fever, and one of diabetes; Dr. G. G. Lewis read a paper on the Pupil in Health and Disease; and Dr. T. H. Halsted read a paper on Direct Examination of the Esophagus and Bronchus, reporting cases and exhibiting instruments.

**The Triprofessional Medical Society of New York.**—At a stated meeting of this society, which was held in New York on Tuesday evening, January 21st, a paper on the Psychic Phenomena of Intestinal Toxæmia and Their Treatment was read by Dr. J. Carlisle De Vries, and a paper on Acute Otitis Media in Infants and Young Children was read by Dr. Arthur J. Herzog. The officers of the society are as follows: President, Dr. J. Monroe Lieberman; first vice president, Dr. G. Morgan Muren; second vice president, Dr. J. Carlisle De Vries; secretary, Dr. Joseph Gutfreund; treasurer, Dr. Daniel E. D. Coleman.

**A Tuberculosis Exhibit in Louisville.**—The tuberculosis exhibit, which was held recently in Louisville by the Kentucky Antituberculosis Association, attracted a great deal of attention and aroused public interest in a most satisfactory manner. As is usual in connection with such exhibits there were various addresses and demonstrations. On January 14th a measure was introduced into the Senate of the State Legislature appropriating the sum of \$75,000 for the establishment of a State tuberculosis sanatorium.

**The New York State Civil Service Commission** will hold examinations on February 15, 1908, for the following positions: Physician, State Hospitals, \$900 and maintenance; Trained Nurse, State Institutions, \$420 to \$500 and maintenance; Orderly, Erie County Hospital, \$540 and maintenance. The last day for filing applications for these examinations is February 8th. Full information and application forms may be obtained by addressing the Chief Examiner of the Commission at Albany.

#### Society Meetings for the Coming Week:

**MONDAY, January 27th.**—Medical Society of the County of New York.

**TUESDAY, January 28th.**—New York Dermatological Society; New York Otolological Society; New York Medical Union; Metropolitan Medical Society of the City of New York; Buffalo Academy of Medicine (Section in Obstetrics and Gynecology).

**THURSDAY, January 30th.**—Brooklyn Society for Neurology.

**Improvements in the Metropolitan Hospital.**—Plans have been filed with the building department for the erection of the following buildings as additions to the Metropolitan Hospital: A four story tuberculosis pavilion with roof gardens, solarium, and exterior verandas, to cost \$180,000; a two story pathological laboratory, to cost \$40,000, and a three story and attic residence for the medical staff, to cost \$80,000. It was erroneously reported in our last issue that these buildings were to be annexes to the Manhattan Hospital.

**New York Academy of Medicine.**—A stated meeting will be held on Thursday, February 6th at 8:30 p. m., under the auspices of the Section in Obstetrics and Gynecology. The evening will be devoted to a review of the recent advances in obstetrics and gynecology, and the following papers will be read: The Present Significance of Chorionic epithelioma, by Dr. James Ewing; Obstetrics, by Dr. Edwin B. Cragin; Gynecology, by Dr. Herman J. Boldt; the Practical Application of Our Recent Knowledge in Obstetrics, by Dr. Edward Reynolds, of Boston.

**The Health of Pittsburgh.**—During the week ending January 4, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Pittsburgh: Chickenpox, 12 cases, 0 deaths; typhoid fever, 66 cases, 19 deaths; scarlet fever, 4 cases, 0 deaths; diphtheria, 15 cases, 1 death; measles, 96 cases, 1 death; whooping cough, 12 cases, 0 deaths; pulmonary tuberculosis, 17 cases, 10 deaths. The total deaths for the week numbered 181 in an estimated population of 403,330, corresponding to an annual death rate of 23.33 in 1,000 of population.

**Medical Society of the County of Oneida, N. Y.**—At the annual meeting of this society, which was held in Utica on January 14th, papers were read as follows: Tuberculosis in Cattle, by Dr. W. G. Hollingsworth; Extragenital Chancere, by Dr. G. M. Fisher; Empyema of the Accessory Sinuses of the Nose, by Dr. T. H. Farrell. The following officers were elected: Dr. Earl D. Fuller, president; Dr. G. M. Fisher, vice president; Dr. Frank D. Crim, treasurer; Dr. W. B. Roemer, secretary; and Dr. Smith Baker, librarian. The retiring president, Dr. Conway Frost, presided.

**To Reorganize the Navy Department.**—Two bills have been introduced into the House of Representatives providing for the reorganization of the Navy Department, one by Mr. Townsend and the other by Mr. Dawson. The latter, H. R. bill No. 12425, divides the work of the department into two divisions, placing the Bureau of Medicine and Surgery under the division of personnel, which is to be presided over by the assistant secretary, who shall be a naval officer. The other division, which is to be known as the division of material, is to be presided over by a civilian secretary.

**The Manhattan Medical Society.**—A stated meeting of this society was held on Friday evening, January 24th. Dr. S. Steiner presented a paper on Acute Appendicitis of the Gall-

bladder, Dr. R. Cronson read a paper on Septic Neuritis in the Puerperium, and Dr. Dexter D. Ashley reported a case of Rheumatism Simulating Hip Joint Disease. After the demonstration of pathological specimens by Dr. J. E. Welch, there was a clinical conference on the subject of Acute Articular Rheumatism. The officers of the society are Dr. Heinrich Stern, president; Dr. Dexter D. Ashley, vice president; Dr. Earle Conner, secretary; and Dr. Albro R. Carman, treasurer.

**The Mortality of Chicago.**—According to the report of the Department of Health for the week ending January 11, 1908, there were during the week 726 deaths from all causes, as compared with 665 for the corresponding week in 1907. The annual death rate was 17.48 in 1,000 of population. The principal causes of death were: Apoplexy, 10; Bright's disease, 52; bronchitis, 25; consumption, 63; cancer, 33; convulsions, 4; diphtheria, 22; heart diseases, 54; influenza, 31; intestinal diseases, acute, 32; measles, 7; nervous diseases, 29; pneumonia, 137; scarlet fever, 13; suicide, 16; typhoid fever, 12; violence, other than suicide, 32; whooping cough, 3; all other causes, 151.

**The Scientific Temperance Federation** held its annual meeting in Boston recently and elected officers for the ensuing year. The reports of the secretaries showed that during the year over a thousand books, pamphlets, etc., had been added to the collection of data on the alcohol question. This special library is at the disposal of all who desire information on the question of alcohol and narcotics. The headquarters of the federation are at 23 Trull street, Boston. Among the corresponding members of the organization are Professor E. Kraepelin, of Munich; Professor A. Aschaffenburg, of Cologne; Dr. Max Kassowitz, of Vienna; Dr. Reid Hunt, of the United States Hygienic Laboratory, Washington, D. C.; and Mr. Walter N. Edwards, F. C. S., of London.

#### Infectious Diseases in New York:

*They are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending January 18, 1908:*

	Jan. 11-18	Jan. 11-18
	Cases.	Deaths.
Dysentery	25	26
Smallpox	0	0
Scarlet fever	209	160
Measles	969	803
Scarlet fever	209	160
Whooping cough	24	14
Diphtheria	37	436
Tuberculosis, pulmonary	442	171
Cerebrospinal meningitis	15	13
<b>Totals</b>	<b>2,615</b>	<b>1,428</b>

**Examination for Physicians in the Panama Canal Service.**—The United States Civil Service Commission announces an examination on February 19 and 20, 1908, to secure eligibles from which to make certification to fill vacancies as they may occur in the position of physician, at \$150 a month, in the Panama Canal Service. It is probable that about fifteen appointments will be made, this estimate being based upon the number of appointments made during the past year. Applicants must be citizens of the United States, graduates of recognized medical schools, and have at least one year's experience as an interne in a general hospital. Men only will be admitted to this examination, and the age limit is twenty to forty-five years on the date of the examination. Applicants should apply at once to the United States Civil Service Commission, Washington, D. C., for application Form 1312.

**The State Campaign for the Prevention of Tuberculosis.**—The tuberculosis exhibit, which was held in Troy recently, was well attended, and public interest was aroused in the question of the prevention of tuberculosis. Lectures, illustrated by stereopticon views, were given each afternoon and evening by the leading physicians and ministers of the city. A permanent committee, composed of the most prominent citizens of Troy, has been appointed by the State Charities Aid Association, which will endeavor to secure compulsory notification and registration of cases, free bacteriological examination of persons believed to be dispensary and visiting nurses, similar treatment for physicians, and the keeping of a health code which will prevent contagion in homes, and the regulation of food supplies. The committee will conduct a campaign from which will be selected suitable and educational campaigns.

**Special Tuberculosis Dispensaries in Chicago.**—According to the Bulletin of the Department of Health of the City of Chicago, during the first three weeks that the six special dispensaries of the Chicago Tuberculosis Institute have been in operation 148 patients applied for treatment. The physicians and nurses attached to this great service report that it is their daily experience to find consumptives living in closest relations with their families and entirely ignorant of the means of preventing infection. In all such instances the dispensary physicians have instituted a manner of living that will be safer for the health of the family and at the same time promote the health of the patient. It is thought that the educational work of the dispensaries will be as valuable as the strictly curative function.

**Personal.**—Professor Cornil has been retired from the chair of pathological anatomy and histology in the University of Paris, having reached the age limit of seventy years.

Dr. David Hilbert, of the University of Göttingen, has been made a member of the Bavarian-Maximilian Order for Science and Art.

Professor Boeckh, of Berlin, has died at the age of eighty-three years. He was well known as a medical statistician and emeritus director of the Berlin Statistical Bureau.

Professor Neisser has returned to London from Bavaria, where he has been for three years studying syphilis in apes. A banquet will be given in his honor on February 1st.

Dr. W. W. McMellan, of Mingo Junction, Ohio; Dr. G. E. Bair, of Braddock, Pa.; Dr. A. J. Frantz, of Seneca Falls, N. Y.; Dr. H. M. Imboden, of Clifton Springs, N. Y., and Dr. J. S. Goodwin, of Spring City, Tenn., are registered at the Philadelphia Polyclinic and College for Graduates in Medicine.

**The Health of the Canal Zone.**—During the month of November, 1907, there were in the Canal Zone 2 deaths from typhoid fever, 33 from malarial fever (clinical), 13 from æstivoautumnal malaria, 5 from hæmoglobinuric fever, 2 from dysentery, 2 from amœbic dysentery, 7 from beriberi, 3 from septiciæmia, 34 from tuberculosis of the lungs, 6 from other forms of tuberculosis, 1 from tetanus, 3 from bronchopneumonia, 22 from pneumonia, 1 from abscess of the liver, 1 from puerperal septiciæmia. The total deaths in the Zone, including Colon and Panama, numbered 267 in a population of 111,007, corresponding to an annual death rate of 28.86 in 1,000 of population. Two white employees from the United States died of æstivoautumnal malaria. The annual death rate of white employees corresponds to 15.35 in 1,000 of population; that of negro employees corresponds to 22.77 in 1,000 of population. The sick rate for employees was 20.49 in 1,000 of population. The death rate of the Canal Zone in November, 1906, was 35.76 in 1,000 of population, and in 1907 it was 28.86 in 1,000 of population—a decided improvement. Mosquito work continues unabated.

**The Health of Philadelphia.**—During the week ending December 28, 1907, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Typhoid fever, 72 cases, 6 deaths; scarlet fever, 51 cases, 3 deaths; chickenpox, 55 cases, 0 deaths; diphtheria, 65 cases, 15 deaths; cerebrospinal meningitis, 3 cases, 1 death; measles, 34 cases, 3 deaths; whooping cough, 18 cases, 8 deaths; pulmonary tuberculosis, 86 cases, 61 deaths; pneumonia, 125 cases, 100 deaths; erysipelas, 5 cases, 3 deaths; German measles, 2 cases, 0 deaths; septiciæmia, 3 cases, 1 death; mumps, 8 cases, 0 deaths; cancer, 25 cases, 33 deaths. The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 8; puerperal fever, 2; diarrhoea and enteritis, under two years of age, 9. The total deaths numbered 601 in an estimated population of 1,500,595, corresponding to an annual death rate of 20.8 in 1,000 of population. The total infant mortality was 12.8; under

one year of age, 10.6; between one and two years of age, 11.1; from one to two years, 10.1; and so on. The total precipitation was 1.62 inches. On the 23d the maximum temperature recorded was 62° and the same maximum was recorded on the 28th. The minimum for the week was 30° on the 22d. This high temperature at a time when the majority of the people were clad for cold weather is probably due to the high humidity and

1. Vasomotor Relations, By W. T. PORTER.
2. The Clinical Importance of the Uneven Distribution of Hydrochloric Acid in the Gastric Contents, By ALBERT E. TAUSSIG and WILLIAM H. RUSH.
3. An Intracranial Papillary Adenofibroma from the Groin, By E. L. YOUNG.
4. The Problem of Expert Testimony, By FRANCIS WAYLAND ANTHONY.
5. Practical Applications of Opsonic Therapy, By THEODORE C. BEEBE and LEON S. MADALIA.
6. The "Optometrist." Does He Preach and Practise Medicine? By JOHN C. BOSSIDY.

1. **Vasomotor Relations.**—Porter in his Harvey lecture speaks also of shock. There has been of late renewed discussion as to the cause of the symptom complex termed shock. Concerning the symptoms themselves, there is very general agreement—the abnormal fall of blood pressure, the failing heart, the low temperature, the apparent depression of the nervous system, are frequent tokens of calamity. It is the apparent depression of the nervous system that has for many years given such favor to the idea that the low blood pressure is the result of exhaustion of the vasomotor centre. We forget that the brain is not an organ, but a region, very large in proportion to the groups of nerve cells that are scattered through it like settlements in a wilderness of fibres. It is forgotten, too, that these cell groups have the most diverse functions. Thus, as in the writer's experiments, the large hemispheres may be roughly taken away without lowering the normal blood pressure and without affecting the vasomotor reflexes, except to increase them. The depression observed in shock does not, therefore, justify any sweeping statements regarding the condition of the many separate nerve organs sheltered by the cranium and the vertebral canal. A clear distinction should be made between the symptoms of shock and shock itself. The symptoms of shock form a clinical entity about which there can be little dispute; shock, on the contrary, is a pathological state, the data of which are at present hypothetical. The hypothesis which constitutes the hitherto generally accepted definition of shock declares that the vasomotor cells are depressed, exhausted, or inhibited by excessive stimulation of afferent nerves. The fall in blood pressure and the accompanying symptoms are declared to be the result of this depression. The vasomotor nervous system seldom, if ever, dilates or constricts all the vessels at one time. The same afferent impulse will cause the vasomotor centre to dilate the vessels of the face, while it constricts those of the abdomen. The effect upon the general blood pressure depends upon the relative size of the dilating and constricting areas. Here the splanchnic nerves, which govern the vessels in the abdomen, have great importance. Shock must, therefore, be studied from a local as well as a general standpoint. The necessity of studying the parts, as well as the whole, will be more apparent when it is remembered that the vasomotor system is composed of three separate neurons—one in the bulb, a second in the spinal cord, and a third out

side the cerebrospinal axis. Experiments undertaken by the author and Dr. Clark show that the several neurons are essentially individual in their action. Were they all of one order, they would react equally to the same stimulus. In other words, the sciatic reflex and the depressor reflex should both be increased or both be diminished by the action of the same agent. We find, however, that they are affected in different way by the same drug. Curare, for example, affects the depressor reflex in one way and the sciatic reflex in another. The experiments seem to establish a specific difference between the bulbar and the spinal motor cells. The more the circulation is studied, the stronger is the conviction that it is not a fixed state, but a sensitive equilibrium, the result of the constantly varying action of a great number of factors. Hence the difficulty of the subject and the necessity of separating the complicated mass problems into simpler problems, capable of answer one by one. Such a separation can be accomplished only in the laboratory, and it is to experimentation upon animals that we must chiefly look for new knowledge in this field.

2. **The Clinical Importance of the Uneven Distribution of Hydrochloric Acid in the Gastric Contents.**—Taussig and Rush observe that, when the stomach contents are expressed and aspirated in the usual manner as completely as possible, the patient sitting erect, only a comparatively small portion of the gastric contents can be obtained. After any of the usual test meals the acidity of the portion so obtained cannot be assumed to represent the acidity of the stomach contents as a whole. If, after this portion of the stomach contents has been removed, the patient is made to lie down, it is usually possible, by means of aspiration, inflation, and the like, to obtain a further considerable quantity of stomach contents. This second portion often differs considerably in its acidity from the first portion. Even after this second portion has been removed, the stomach still contains considerable unobtainable residue. The amount of this is apparently independent of the total quantity of gastric contents, and probably varies from one to three ounces. Of its degree of acidity we can know nothing; certainly we have no ground for the assumption that it is identical with the acidity of the contents obtained for examination. The quantitative determination of the acidity of the gastric contents is thus seen to be subject to a grave source of error. This will be diminished if the contents obtainable in the prone position are also examined. It will be further lessened if the acidity of the two portions does not differ very widely, since then we may assume that the acidity of the unobtainable residue will itself not be very different. It follows that, in practice, trustworthy results can be obtained only if the following precautions are observed: The stomach contents must be obtained separately in the erect and in the prone posture; the acidity of each portion must be determined and diagnostic conclusions, based upon the degree of acidity, can be drawn only if the two acidities correspond fairly well, or if the total quantity of gastric contents obtained is so great that the unknown acidity of the unobtainable residue may be neglected.

By SMITH ELY JELLIFFE.

2. **Arteriosclerosis.**—Walton and Paul conclude that, while arteriosclerosis is directly productive of apoplectic attacks and of vertigo and plays a part in the loss of memory as well as of other failing powers of involution, it does not produce headache except as the immediate result of apoplectic attacks. Arteriosclerosis naturally appears in a certain proportion of elderly neurasthenics as in any group of elderly persons, but their observations fail to establish its causative influence, and the authors feel that further study of this branch of the question is desirable. Renal degeneration is a prominent factor in the cardiac enlargement often present in cases of arteriosclerosis. Arteriosclerosis without cardiac enlargement or renal degeneration is only exceptionally accompanied by a very high blood pressure. If either cardiac enlargement or renal degeneration is present, moderately high blood pressure; if both are present, very high blood pressure, is the rule.

4. **Subacute Polymyositis.**—Burley, in speaking of the pathology of subacute polymyositis, remarks that the post mortem findings in these cases are variable, depending largely on the stage of the process. A majority of his cases had reached the later or destructive stage, the early or inflammatory stage being less in evidence except when a specimen of muscle was removed during life. The signs of inflammation, including swelling, infiltration, transudation, and hæmorrhage, were found early, affecting largely the connective tissue, in part the parenchyma. It was characteristic of the disease that certain bundles and certain fibres of a bundle were unaffected by the process. With the progress of the disease attempts at regeneration were commonly seen in the great increase of nuclei, including mitotic forms, while at the same time the anatomical picture of destruction of fibres was prominently seen. This appeared as granular, and, later, waxy degeneration of the fibres; vacuolation, a great increase of cells and fat globules, greatly thickened perimysium becoming myxomatous or fibrous in structure, in fact a tendency to the embodiment of the former specific tissue into a connective tissue structure. The nerves have been shown to be involved in a number of cases,

notably those of Senator, but from their distribution and from the considerable number of normal fibres found in the sections it seems probable that the process is not primary in the nerves. The amount of hæmorrhage between the muscle bundles is variable. It may be very great, predominating in the sections and giving rise to the name polymyositis hæmorrhagica. Of the treatment, he says that attempts to cut short the course of the disease by any specific form of treatment have heretofore been of little avail. Antipyretics and salicylates have somewhat relieved the pain and soreness of the early stages. Hot baths and fomentations had been moderately used before, but in 1903 Oppenheim came forth with glowing accounts of five cases, which led him to advocate confidently the systematic use of diaphoresis. His method was to apply hot air, then wrap in blankets, giving hot drinks and aspirin. The patient was thus sweated for an hour at least every second day. Thermomassage was used on the alternate day. Later simple massage and electricity were used. Oppenheim considered this treatment a great factor in the recovery of his cases, though it did not serve Burley as well in the one case on which he had an opportunity to try it. The test of time will alone determine its value.

**8. A Clinical Study of the Bromine Compounds, with Special Reference to Strontium Bromide.**—Robinson thinks that the bromides are valuable and sometimes indispensable agents. Potassium bromide is the worst bromide we possess, its undesirable by effects by far overbalancing its therapeutic value. Whoever administers potassium bromide in large doses for a long time is simply slowly poisoning his patient. Sodium bromide is a much milder bromide, and when chemically pure strontium bromide is not available, sodium bromide is the salt of choice. Strontium bromide is the best of all inorganic bromine compounds. It is a positive anaphrodisiac, and a positive nervous and genitourinary sedative; it does not upset the stomach, and does not produce acne, or, if it does produce a few acne pustules, they are mild and transient; it often acts as a mild intestinal antiseptic, does not irritate the kidneys—rather the contrary—and has a tendency to diminish albumin in albuminuria and sugar in glycosuria. The dose of strontium bromide ranges from 10 to 60 grains three or four times a day. Occasionally it may be given in doses of one or two drachms. It is best prescribed dissolved in distilled water with the occasional addition of essence of pepsin, tincture of cardamom, etc. Strontium bromide is incompatible and should not be prescribed with citrates or sulphates, and it is also best to avoid prescribing it with alkaloids. To obtain the good results from strontium the salt must be chemically pure. If contaminated with barium, as the commercial strontium salts not only frequently but usually are, its effects will be disappointing and its untoward by effects may be more severe than those of potassium bromide.

**11. Some General Reflections on the Psychology of Dementia Præcox.**—Jelliffe, speaking of the therapeutics, states that many præcox demented, in fact, the most, are probably doomed from the very beginning. What with bad structure on which to build, bad environment, and possibly a

toxic factor (only postulated hypothetically), there is little opportunity for some præcox demented. But a few are worth working for, particularly in the prædementia stage. When the diagnosis is more or less patent the process has been too long in the making and the opportunities for repair have usually been neglected. The eccentric, egocentric child is always a difficult problem from the standpoint of training. Too many are permitted to go their own way in the hope that all will be well when they mature. A large number of præcox demented are drawn from this class. The author believes, in the first place, in teaching the children the petty conventions of life which make so frequently the oil that reduces social friction; the help in permitting an adjustment to unpleasant situations which thus diminishes the opportunities for affective action. It is simple to say that a child should be trained to his *métier*, but extremely difficult to determine just what individual capacity is. In an interesting comparison made by Gaupp relative to the psychoses of urban and of rural communities, it appears that the stress of city existence bears particularly on the young mind and determines the hysterical and præcox reactions in the young more frequently in the city than in the country. This is a fact worth bearing seriously in mind if heredity and peculiarity are present in a child. Schooling work does not seem to make a marked difference if it is pursued in moderation. The brighter, eager brains are more often damaged than those less pushing, and each individual child's reaction to its school work is worthy of close observation. If the reaction to intellectual work is not normal—if fatigue enters as a large disturbing element—care should be exercised in so arranging studies as to obviate it. These children need schools in which outdoor pursuits are cultivated and made coordinate with or supplemental to more intense intellectual efforts. There are a large number of ideas of primary importance in the care of this particular type of breakdown. Many are not hopeless by any means; they need the proper type of education, and scientific pedagogy looks to the physician to indicate the lines of development for this class of true mental healers.

#### MEDICAL RECORD January 18, 1908.

1. Anorectal Fistula, By CHARLES B. KELSEY.
2. Schlosser's Alcohol Injections for Facial Neuralgia. Sixteen Months' Experience with Fifty-five Cases; Three Failures, By OTTO KILIANI.
3. Instruction in Hydrotherapy, By SIMON BARUCH.
4. The Treatment of Chorea Minor, with Special Reference to the Dangers of the Arsenic Therapy, By HENRY KOPLIK.
5. Medical and Scientific Work in New York State Charitable Institutions, By ANDREW MACFARLANE.
6. Prevention of Death During Anesthesia by Chloroform and Ether, By ROBERT REYBURN.
7. Writers' Cramp; What it Is and How it Can Be Treated by the Family Physician, By S. H. MONELL.
2. Schlosser's Alcohol Injections for Facial Neuralgia.—Kiliani reports his experience during sixteen months with fifty-five cases, only three of which were failures. In all cases he has made peripheral injections first, even if he expected to inject into the ganglion. All the injections were done without any narcosis or local anesthesia. The

insertion of the blunt needle into the foramen is rather painful; the slow injection of the alcohol somewhat more so, but not beyond the endurance of the patients, who are accustomed to a great deal of pain. Every successful injection must produce, within a few minutes, a burning or numbing sensation within the region of the nerve injected. This develops, sometimes after a severe period of pain for two or three hours, into a more or less pronounced anaesthesia. Any of the three peripheral injections produces a swelling, which in the first and second branch results in oedema of the eyelids, and in the third branch sometimes in a slight trismus. Nearly every injection into the second branch through the foramen infraorbitale produces a slight facial paresis, owing to the connecting branch of the ganglion sphenopalatinum with the loop of the facial nerve. This paresis disappears within a period of from three days to two weeks. To reach the part of the second branch which supplies the roof of the mouth and the roots of the rear teeth, it is sometimes necessary to inject into the ganglion sphenopalatinum, a procedure which he has ventured only lately, as he was afraid of the entrance of the alcohol through the outer fissure into the orbita, with its possible disastrous results on the eye muscles or even the optic nerve. But a carefully slow instillation has prevented any trouble so far. Injection through the foramen ovale or rotundum into the root of the second or third branch, or the ganglion itself, must at once produce, if carried out properly, a complete anaesthesia in the region of the nerve attacked. Only if gasserectomy has been done before, the effect may be delayed, owing to the scar tissue resulting from the former operation. The number of injections necessary to produce freedom from pain ranged with the first branch from two to four; with the second from four to sixteen; with the third from two to five. The time occupied to get the patients free of pain varied from three days to five weeks. The diagnosis of facial neuralgia rests, to a large degree, upon the statements of the patients, although a typical severe paroxysm cannot be mistaken for anything else. It is, therefore, only fair to pronounce a patient cured for the time being only if the patient says so himself.

7. **Writers' Cramp.**—Monell states that the main indications for treatment are, broadly, two: the elimination of the toxic products which result from high pressure muscular work and part of which gradually stagnate in the tissues, and the improvement of the nutrition of the affected tissues so that the powers of recuperation are renewed. The first of these indications is admirably met by means of the modern electric light radiant heat cabinet bath, and if this is not available for the practitioner he should advise a course of Turkish baths as the next substitute. The measures of direct treatment are comprised in the resources of electrotherapeutics. In employing these resources there are but three requisites to success: a determination of the therapeutic actions which must be set up in the tissues to promote their restoration to normal, the selection of the means of best setting up the desired actions, and the technical knowledge of how to make the selected agent do the therapeutic work

that the operator intends it to do. No special skill, apart from a general command of the resources of modern electrotherapeutics, is therefore required to enable the physician to undertake a case of writers' cramp if he will first acquire an understanding of the conditions to be treated and the indications present in the given case. The writer has variously employed with success all the currents. The galvanic current, currents from fine high grade faradic coils, the great resources of static electricity, and high frequency apparatus can all be made to do the work demanded, provided the given apparatus has efficient therapeutic resources and the means of applying them. In most cases it will be necessary to improve the quality of the blood as well as the circulation through the affected tissues, for anaemia, if present, retards the regenerative processes. A sedative tonic action is also indicated to allay irritability and remove aches and pains. Tonic contractions of the affected muscles are always needed, but must be carefully "dosed" to avoid the reactions of fatigue. The physician who is well grounded in the ordinary principles of current control, actions, and dosage can easily apply his knowledge to the relief and improvement of writers' cramp, and in early cases can rapidly restore the arm to normal endurance and comfort. The mental relief to the patient will be incalculable.

3. Cancer of the Ovary, By J. BLAND-SUTTON.
4. Some Recent Experiences in the Surgery of the Liver and Gallbladder, By J. L. THOMAS.
5. Some Recent Developments in Our Knowledge of Syphilis in Relation to Diseases of the Nervous System, By F. W. MOTT.
6. A Note on Excessive Patellar Reflex of Functional Nervous Origin, and Especially the "Tropidon" or "Spinal Epilepsy" Form, By F. P. WEBER.
7. Typhoid Carriers, By A. LEDINGHAM and J. C. G. LEDINGHAM.
8. The Contents of Irreducible Inguinal Hernia in Female Subjects, and True Hermaphroditism, By E. CORNER.
9. A Note on Nephropexy, By F. ERE.

1. **Knee Joint Injuries.**—Bennett discusses the various modifications of movement at the knee which occur either immediately after an injury or supervene after an interval without the intervention of any organic disease of the joint. Complete locking of the joint immediately after injury is usually due to some mechanical obstacle. The commonest cause is displacement of one or both semilunar cartilages, especially in patients under thirty-five years of age. Hypertrophied synovial fringes give rise to obstruction in older subjects. Other causes are an abnormal flap of synovial membrane, underlying and adherent to the patella, completely loose bodies ("loose cartilages"), bodies attached by a long pedicle, pieces of bone broken off from the condyles of the femur. Apparently complete locking of the knee joint, in the absence of anasthesia, may be due to synovial spaces secondary to pain. In all cases an anæsthetic should be given as soon

as possible, in order to determine how much of the limitation of movement is due to muscular spasm.

**3. Cancer of the Ovary.**—Bland-Sutton states that primary cancer of the ovary is a very rare disease. The most remarkable feature of secondary masses of cancer in the ovaries is the large size they sometimes attain, while the primary growth is so small and inconspicuous as to be overlooked unless specially sought for. The view that these large malignant bilateral tumors in the ovaries are secondary to cancer in other organs rests on the fact that the structure of the ovarian mass varies according to the situation of the primary cancer. Some of these large tumors may be explained by the fact that the cancer cells may engraft themselves on a preexisting ovarian cyst. Primary cancer of the Fallopian tube is a very fatal disease. Its bad effects are greatly modified according to the condition of the celomic ostium of the tube. When this ostium remains open the cancer cells quickly infect the pelvic peritonæum; if it becomes occluded, which is rare, the infection of the peritonæum is greatly delayed. From an operative point of view these opposite conditions are of great importance. The removal of a cancerous Fallopian tube with a patent celomic ostium is usually followed by recurrence in a few months. The lethal effects of a carcinoma are not so much due to the primary tumor as to the accidents which arise from it. When an ovary becomes infected with secondary cancer it is free for a long period from the usual liability to septic infection, and the cancerous masses may thus attain unusual size. No case can now be accepted as primary cancer of the ovary merely on a laboratory report; a primary focus elsewhere must be most painstakingly sought for.

**5. Syphilis and Locomotor Ataxia.**—Mott accepts the *Spirochæta pallida* as the specific virus of syphilis, and suggests that it may vary in its virulence and toxicity, not every variety producing the special neurotoxine. Some forms of the protozoon may be attenuated in their virulence, owing to the passage of the organism through the bodies of certain individuals. The writer holds that syphilis is the essential cause of locomotor ataxia and general paralysis. Among the facts on which he bases his belief are the following: 1. Erb's statistics. 2. The cerebrospinal fluid of tabes, general paralysis, and syphilitic meningitis invariably contains lymphocytes and no polymorphonuclears. This occurs in no other chronic affection of the nervous system, except sleeping sickness. 3. Antisyphilitic bodies exist in the serum and cerebrospinal fluid of tabes and general paralysis, the quantity increasing in amount as the disease progresses. 4. Primary chances are exceedingly rare in early paralytics, in spite of the promiscuous sexual intercourse so frequently observed among them. 5. In 80 per cent. of forty cases of juvenile general paralysis, the writer found syphilitic antecedents. 6. The Argyll Robertson pupil and the irregular pupil are practically only met with in general paralysis, tabes, and syphilis; it may be the sole sign of syphilis. Parasyphilitic disease of the nervous system depends upon two factors: intrinsic, innate, and extrinsic, acquired—the soil and the seed; the vital

resistance and the specificity of the virus. All those conditions, which may be inherited or acquired, and which tend to active metabolism of systems, communities, and groups of neurons functionally correlated, and which, owing to those conditions of stress which in one individual would cause spinal neurasthenia, will, in conjunction with the stimulating effect of the syphilitic poison, cause the nerve cells to exercise an abnormal metabolic activity in the production of the side chain molecules necessary for immunization against the toxic effects of the virus. The frequent indulgence of abnormally strong sexual desires, stimulated by many causes, especially alcohol is, after syphilis, the most important factor in the production of tabes and general paralysis. It acts in two ways: (1) Directly, by exhaustion of neuropotential; (2) indirectly, in the male by the excessive loss to the body of highly phosphorized nucleoproteids contained in the sperm. These are biochemical substances possessed of great specific energy and not easily replaced.

**6. Excessive Patellar Reflex.**—Weber holds that excess in the patella reflex in functional cases is due to a peculiar functional condition of the cerebral cortex, which, when present in greater degree, gives rise to the "trepidation" form of reflex and to "functional ankle clonus." This condition may be excited or modified by temporary emotional factors, and a similar state may be induced by toxæmias, such as uræmia. The signs of this functional cerebral condition may be imitated by organic nervous disease, such as cerebral hæmorrhage, disseminated sclerosis, etc. In "functional nervous vomiting" we probably have to deal with an analogous functional change in the brain.

**7. Typhoid Carriers.**—Ledingham and Ledingham, in investigating ninety women, found three of them to be "typhoid carriers"—i. e., while in good health themselves, they constantly excreted typhoid bacilli in their stools, and so were dangerous sources of infection. It is probable that in these cases the bacilli vegetate in the gallbladder, from which they are intermittently ejected into the intestine. No so called intestinal and urinary antiseptics seemed to have any effect. Such persons should be kept constantly under bacteriological supervision. Dehler actually performed cholecystostomy and drainage of the gallbladder on two asylum carrier cases, though in neither were there any symptoms pointing to disease of the gallbladder. In a few months the typhoid bacilli disappeared from the fæces, and the blood lost its power of agglutinating typhoid bacilli.

**9. Nephropexy.**—Ere advocates a new operation for performing nephropexy, the principles underlying which are as follows: 1. That owing to the friability of the renal tissue the capsule only should be used for its fixation. 2. That a decorated surface of the kidney should be brought into immediate relationship with the quadratus lumborum and psoas, on which it normally lies, without the intervention of any connective tissue. 3. That no suture should be affixed to the capsule of the kidney in its upper third, as when passed through the parietes they would, as a rule, fix the kidney in a position below that which is normal.

4. A Preliminary Note on the Kinematograph in Medicine, By H. C. THOMSON.
5. Diabetes Mellitus in Two Brothers, with Necropsies, By W. C. BOSANQUET.
6. A Case of "Diphtheria of the Skin" of Three Years' Duration Treated by Antitoxine, By A. B. SLATER.
7. An Unusual Pathological Condition of Meckel's Diverticulum, By C. H. TURNER.
8. Delirium Tremens (Mania e Potu): Statistical Study of 156 Cases, By L. N. BOSTON.

5. **Diabetes Mellitus.**—Bosanquet reports two fatal cases of diabetes mellitus occurring in two brothers. Among the points of interest were the following: 1. The hereditary incidence of the disease was well shown, no less than four members of one family being affected. Alopecia areata also occurred in three of the cases. 2. In one case the onset of the disease was very rapid and accompanied by abdominal pain, suggesting an acute affection of the pancreas. In the other case the onset was insidious. 3. In one case the patient passed into a deep state of coma, and yet recovered for a time, dying comatose eventually, the kidneys showing acute inflammation. The acetonæmia did not depend on any lack of carbohydrate food. 4. In one case the amount of sugar in the urine varied independently of the diet taken, thus bearing out the author's views as to the origin of sugar in diabetes, viz., that some portion of the sugar arises from a breaking down of the cells of the body, in addition to that which may be due to some defect in the process of absorption of sugar from the alimentary canal or of its destruction in the body. 5. Secretion failed to act beneficially in either case. Its employment in diabetes can only be upheld on the principle that the formation of the internal secretion of the pancreas and that of the digestive ferments take place as a single chemical action, the lining substance breaking down simultaneously into both these substances. 6. In both cases the anatomical condition of the pancreas was striking; in each there was marked atrophy of the organ without noteworthy alteration of structure. In both there were plenty of normal looking islands of Langerhans, thus tending to support the view that the typical condition of the pancreas in diabetes is atrophy, affecting the secreting cells as a whole. In both cases there was well marked arteriosclerosis, which is the most constant feature in the pancreas in cases of diabetes.

## LA PRESSE MEDICALE.

December 31, 1907.

1. Technique of Kraske's Operation, By R. PROUST.
  2. Spontaneous Rupture of the Aorta, By MAURICE LIEBOWITZ.
  3. Technique and Value of the Microbiological Examination in Syphilis, By A. SEZARY.
  4. Method of Measurement of Shortening of the Thigh, By H. FORESTIER.
  5. Painful Points and Contracture of the Abdominal Wall, By R. ROMME.
1. **Technique of Kraske's Operation.**—Proust

gives each step of this operation for the extirpation of cancers situated high in the rectum, clearly illustrated from the exposure of the sacrum to the uniting of the divided ends of the intestinal canal to bring about its reestablishment.

2. **Spontaneous Rupture of the Aorta.**—Liebowitz says that atrophic atheroma of the aorta and arterial syphilis form the two well recognized varieties of antecedent disease favorable to spontaneous rupture of the arch, an accident almost unknown to the aorta in its thoracic abdominal portion. Chronic atrophic nephritis, acting through the hypertrophy of the left side of the heart and the arterial hypertension which ordinarily accompanies it, is the usual active agent in the production of the rupture of the internal membrane of the aorta. The commencement of the aorta, above the semilunar valves, is its weak point and the place of predilection for spontaneous ruptures. Every rupture of the arch is not necessarily fatal.

3. **Microbiological Examination in Syphilis.**—Sezary asserts that the microbiological examination for the *Spirochæta pallida* can determine accurately the diagnosis of syphilis, and if the technique is well observed the negative results will be few. Under such rare circumstances, in the absence of a method of culture and while waiting for a satisfactory method of serum diagnosis, if recourse cannot be had to experimental inoculation on an ape, reliance must be placed on the histological study, which elsewhere is always very explicit.

4. **Measurement of Shortening of the Thigh.**—Forestier places the patient lying face downward on a table, so that his thighs hang over the edge, in a vertical position, the legs flexed and supported by the toes. The pelvis is supported by the iliac spines resting on the edge of the table, which gives a fixed and precise upper point to measure from. A lower fixed point is readily obtained and exact measurement is easy.

## BERLINER KLINISCHE WOCHENSCHRIFT.

December 23, 1907.

1. Foreign Body for Two Years in the Left Bronchus. Direct Extraction. Recovery, By H. VON SCHROETTER.
2. Concerning the Development and the Present Position of the Serum Diagnosis of Syphilis, By A. WASSERMANN.
3. The Technique, Certainty, and Clinical Importance of Wassermann's Reaction in Syphilis, By G. MEIER.
4. Critical and Therapeutic Contributions to the Knowledge of the Quartz Lamp, By R. LEDERMANN.
5. Concerning Suboccipital Inflammations, By I. GREENSWALD.
6. Neuralgia of the Rectum, By A. VERR.
7. A Rare Case of Nervous Erection, By S. SAITO.
8. Epiphthalmic Gait and the Sexual Life of Women, Concluded, By K. KERN.

1. **Foreign Body in the Left Bronchus.**—Von Schroetter states that, although he has been engaged in the examination of the upper air passages for eight years and has seen a large number of foreign bodies during that time, he has never before met with a foreign body in the left bronchus. He reports the case of a man, fifty-two years of age, who inhaled a foreign body in September, 1905, which caused difficulty in breathing and cough, followed by a purulent expectoration, which persisted through

1906 and 1907 up to the time of the removal of the foreign body. The patient had repeatedly sought relief from emphysema, bronchitis, and other affections of the air passages. On August 28, 1907, the foreign body was discovered by means of bronchoscopy, and proved to be a fragment of bone, which was easily removed.

**2. Serum Diagnosis of Syphilis.**—Wassermann asserts to have proved to be diagnostic the property of the body fluids of syphilitics to unite with certain lipoids.

**3. Wassermann's Reaction in Syphilis.**—Meier gives in detail the technique of the serum diagnosis of syphilis as practised by Wassermann. His clinical results were, out of 181 positively syphilitic cases, there was a positive reaction in 148 (81.7 per cent.), doubtful reaction in five (2.7 per cent.), and a negative in twenty-eight (15.6 per cent.). The reaction was negative in all of twenty-one cases in which syphilis was positively excluded. He says that the reaction may take place in all stages, but is more marked in the later stages, a point of practical importance, as in the late stages difficulties in diagnosis are often present. In almost every case of tertiary syphilis the reaction was strong. In a certain set of syphilitic cases the reaction was negative, and this needs further investigation. Finally he holds that Wassermann's reaction is specific for syphilis, which, because of its great certainty, is a true enrichment of our means of diagnosis, but its complicated technique necessitates the employment of an experienced investigator in order to obtain unobjectionable results.

**5. Suboccipital Inflammations.**—Grünwald refers to inflammations in the region of the articulation between the atlas and the occiput and reports four cases, one of probably syphilitic, the other of otitic origin.

**6. Neuralgia of the Rectum.**—Albu describes two cases of neuralgia of the rectum. In the first case the neuralgia was occasioned by a developing carcinoma of the prostate, in the other it was an accompaniment of tabes.

**7. Nervous Eructation.**—Saito describes a case of nervous eructation of thirty-six years' standing which he met with in a woman, seventy-eight years of age, and cured by forcing her to keep her mouth open for an hour or two at a time and so preventing her from swallowing air.

**8. Exophthalmic Goitre and the Sexual Life of Women.**—Kron declares that if exophthalmic goitre comes on before or in the early part of pregnancy the disease may become worse and the development of the child will be interfered with, with a resultant miscarriage, because the thyroid gland is insufficient to furnish the needed material to the embryo, and after the birth the mother regains more nearly her normal condition because the pathologically changed gland furnishes sufficient secretion. But if the disease appears during the second half of pregnancy it has no influence on the embryo because it has its own thyroid. The mother, however, is still in danger. It is probable that in a woman sexually mature exophthalmic goitre is a disease of metabolism.

# MÜNCHENER MEDIZINISCHE WOCHENSCHRIFT.

December 17, 1907.

1. The Technique of the Determination of the Opsonins and its Use in Tuberculosis of the Lungs, By BISE and LISSNER.
2. Comparative Studies Concerning the Diagnosis of Typhoid by Means of Bacilli Emulsion and Ficker's Diagnosticum, By SCHRUMPF.
3. Studies Concerning the Functional Behavior of the Vessels in Trophic and Vasomotor Neurosis, By CURSCHMANN.
4. The Value of the Negative Result of the Bacteriological Investigation of the Blood of the Sinus in the Distinctive Diagnosis between Otitic Sinus Thrombosis and Other Not Yet Manifest Febrile Diseases, By NÜRNBERG.
5. The Treatment of Tuberculosis of the Kidney by Means of the X Rays, By BIRCHER.
6. The Radical Operation of Diverticulum of the Oesophagus, By GEHLE.
7. The Treatment of Inoperable Cancer of the Uterus with Aceton, By GELLHORN.
8. A Serious Complication in Acute Gonorrhœa, By MÜHLIG.
9. Gangrene of the Scrotum after Application of Tincture of Iodine, By HANASIEWICZ.
10. Hypertrophy of Langerhans's Islands of the Pancreas, By HEIBERG.
11. Objects and Methods of Instruction in Gynecology, By VON FRANQUÉ.
12. The Behavior and Reform of Midwives, By HENKEL.

**2. Comparative Studies Concerning the Diagnosis of Typhoid by Means of Bacilli Emulsion and Ficker's Diagnosticum.**—Schrumpf says that in ten cases out of forty-nine in which an infection with typhoid bacilli was positively present the agglutination test with the diagnosticum was negative, while with a fresh bacilli emulsion it was positive. In six of these ten cases agglutination with the diagnosticum could not be obtained when the test was repeated on different days of the disease, in three the agglutination with the diagnosticum took place, in the later part of the course of the disease, while in one it was present at first but lost later. Hence the result obtained with paratyphus B diagnosticum were faulty, and the method unreliable.

**5. Treatment of Tuberculosis of the Kidney by Means of the X Rays.**—Bircher reports two cases in which he obtained favorable results from the methodical use of the x rays. He recommends this form of treatment for those cases which are not operative, as the patients can lose nothing thereby but may gain.

**6. The Radical Operation for Diverticulum of the Oesophagus.**—Gehle reports a case in which he successfully removed a diverticulum of the oesophagus from a man sixty-nine years of age. The condition is rare, and the results of operative removal have been altogether such as might be desired, some patients dying in from one to eight weeks after operation, a fistula remaining in others. Hence it would be better for any one who may have occasion to perform such an operation to read the details of the technique employed by this surgeon in his original language.

**8. A Serious Complication in Acute Gonorrhœa.**—Mühlig reports a case in which an acute gonorrhœa was complicated by a bilateral infarct of the lungs. He thinks that the gonorrhœa caused a deferentitis spermatica gonorrhœica which pro-

duced a thrombosis of the venæ spermaticæ internæ, whence emboli were transmitted to the lungs.

9. **Gangrene of the Scrotum After the Application of Tincture of Iodine.**—Hanasiewicz reports the case of a man, nineteen years of age, who had painted his scrotum with iodine because of a painful swelling of the testicles of unknown origin. As a result the scrotum became gangrenous and sloughed, leaving the testicles exposed. The granulating surface that was left was covered with Thiersch grafts with good result. The cause of the primary epididymitis could not be ascertained. The patient had no discharge from his urethra, denied any venereal infection, but acknowledged the possibility of a traumatism. The author believes that the gangrene was the direct result of the application of iodine and recommends that such applications should never be made in cases of acute inflammation, but should be reserved exclusively for cases of chronic or slight inflammation.

#### ARCHIVES OF PÆDIATRICS.

December, 1907.

1. On the Bacteriology of Meningitis. By F. S. CHURCHILL.
2. Proteid in Infant Feeding; the Necessity of a Standard. By T. S. ALLEN.
3. Variation in Fat Content of Cows' Milk. By E. H. BARTLEY.
4. A Case of Vomiting with Acetonuria and Fatty Metamorphosis of the Liver. By A. W. MYERS.
5. Estivoautumnal Fever in a Child Two and a Half Years Old. By R. O. CLOCK.
6. Sarcoma of the Kidney in Children, with Report of a Case. By W. SHANNON.
7. Remarks on the Exudative Diathesis of Czerny. By A. HEYMANSOHN.
8. The Report of a Case of Retropharyngeal Abscess in a Girl Eleven Years Old. By H. B. CARPENTER.

2. **Proteid in Infant Feeding; the Necessity of a Standard.**—Allen finds three ways for determining such a standard: 1. By determining the nitrogen waste in the urine of babies fed first on a proteid free diet, then the nitrogen excreted with a proteid diet varying in quantity. The difference between the proteid ingested and the proteid equivalent of the nitrogen excreted with varying amounts of proteid will be the minimum proteid necessary for cell growth. 2. The minimum proteid quotient may be fixed at 4 and the maximum at 6. 3. By studying a number of cases in which the babies' weight, the quantities of milk taken in a day, and the proteid content of this milk were all recorded. Having obtained a standard, the minimum daily proteid may be regarded as supplied by one ounce of milk for each pound of infant's weight, while the maximum daily proteid quotient, which is placed at 6, will be supplied by one and one-half ounces of milk. This application of the maximum and minimum daily standards is available either with whole milk, skim milk, buttermilk, top milk, or a mixture of cream with either whole milk or skim milk.

4. **Vomiting with Acetonuria.**—Myers records the case of a fairly healthy child of two years who, without discoverable cause, developed a severe vomiting attack, with acetone and diacetic acid in the urine. After apparent recovery lasting ten days, profound intoxication developed, though the diet had been most judicious, and death quickly re-

sulted, after severe nervous symptoms. The liver was fatty and the stomach was full of more or less decomposed blood. Conditions like this are thought to be frequent in cases in which the food is too rich or too abundant. Vomiting may also be precipitated by fatigue or over excitement. The author disagrees with the view that the acetonuria results from temporary tissue starvation due to persistent vomiting. The presence of acetone in the urine in digestive disorders is of value as a sign of liver insufficiency and may be a valuable danger signal calling for extreme watchfulness.

7. **The Exudative Diathesis of Czerny.**—Heymansohn refers to Czerny's description of certain phases of what was formerly called scrofulosis and which he now terms *exudative diathesis*. This condition rests upon a congenital anomaly of the organism, heredity being an important factor. It is common during the first year of life. Diarrhoea may be present or there may be no gastrointestinal trouble. There may be a gain in weight, but fat is excessive, muscle defective. Symptoms which are prominent are thickening of the lingual mucous membrane, seborrhoea of the scalp, strophulus, prurigo, intertrigo with severe itching and glandular enlargements. In older children the mucous membrane of the nose, throat and lungs is more or less diseased, and there are usually anorexia, constipation, fetid breath and anæmia. Tuberculosis in these cases may be excluded. In treatment Czerny recommends the following brief rules: (1) Careful feeding, (2) care of the nervous system, (3) avoidance of intercurrent infection.

1. **Tuberculosis in the United States Navy.**—Surgeon General Rixey speaks very interestingly of the achievements and the progress made in treating tuberculosis patients in the United States navy. But the main point here, too, is the prophylaxis. In the matter of recruiting, great pains should be taken to detect tuberculosis in its incipient form before the recruits are drafted into active service; and as regards enlistment we must insist on a minimum standard of physical development and age. Until it is more fully realized that tuberculosis is a disease of nutrition and until a minimum standard of physical requirement is more consistently exacted, we will not have started in a fair way to materially reduce the tuberculosis in the service. This is particularly true of the engineer's force, which necessarily has much hard labor to perform below decks during the short stops in port as well as at sea. The duties of the engine and fireroom forces represent the extreme of the different occupations which keep men below deck and which contribute the greatest number of cases of tuberculosis. The engineer's

force is particularly subject, moreover, to pulmonary affections consequent upon sudden changes from a high to a low temperature, or even a cool one. Frequent and sudden chills from such causes may be prevented with due and possible care. The men must be made to understand the dangers in leaving overheated localities and going immediately under a ventilation shaft or on deck or into the cold storage compartments without necessary precautions such as drying the skin of perspiration and protecting the body by additional clothes, according to the season or climate. And it should be avoided as much as possible that the men in the engine and boiler rooms and other particularly warm places be called suddenly for duty on deck. In this case, unless an emergency is to be met, they should be given time to dry the body and put on the necessary additional garments. As regards recreation and exercise, it is a serious mistake to suppose that the various athletic sports, exercises, and diversions engaged in by enlisted men constitute all that is required for their physical development. As a large proportion of the enlisted force are mere boys not fully grown, their development requires outdoor life of a regular, active character in order to make them vigorous men able to withstand the hardships of warfare or prolonged physical strain of any kind. The value of the setting up drill, particularly the breathing exercise, as a prophylactic measure against pulmonary tuberculosis in the navy cannot be overestimated, but it is believed that steps should be taken to give with more certainty all the enlisted personnel a larger proportion of time out in the sun than is secured by virtue of occasional athletic exercises. Long marches in light marching order, taking half the crew at a time except those debarred by sickness, or regularly sending the men out in sailing or pulling boats are suggested procedures; indeed any such practices might meet the desired end and would not only be of immense benefit to health, but would also be welcomed by the men as a relief from the monotony of ship life. Proper rest and food of course have a very decided bearing upon the conservation of vital resistance in the prophylaxis against tuberculosis, but these latter considerations, it is believed, are well met in the United States navy. The problem of treatment largely resolves itself into dietetic and hygienic considerations, with building of sanatoria.

### Proceedings of Societies.

#### SOUTHERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.

*Twentieth Annual Session, Held in New Orleans,  
December 17, 18, and 19, 1907.*

The President, Dr. HOWARD A. KELLY, of Baltimore, in the Chair.

*(Continued from page 138.)*

**Thrombosis and Hydrocele in the Inguinal Canal.**—Dr. JOSEPH RANSOHOFF, of Cincinnati, called attention to mild cases of torsion of the cord, of which he reported three cases following severe strains. In one there had been a hernia, and the condition followed the use of an ill fitting truss. In none of the cases did thrombosis occur in the subject

of a varicocele. Under expectant treatment the thrombosis disappeared. A number of cases of hydrocele of the cord within the canal were presented as a sequence of thrombosis. One was clearly a hæmatocele with thrombus following an injury. In three other cases the operation showed the thrombosed vein and the hydrocele. One specimen presented was of the rare form of bilocular hydrocele of the canal of Nuck. The patient was twenty-eight years of age. After a strain and slight illness a hydrocele developed, part of which was in the labium majus, the other properitoneal. The operation, which consisted in total enucleation of the sac, showed a thrombosed vein.

The essayist also presented a multilocular hydrocele of the inguinal canal without any communication with the abdominal cavity and without any history of trauma. He believed that all cystic tumors within the canal resulted from thrombus and effusion into an unobliterated portion of the vaginal peritoneal process. In his paper he alluded only to cystic conditions of the canal which were secondary to hernias and resulted from the sequestration of a portion of the sac.

**Traumatic Epilepsy.**—Dr. E. DENEGRE MARTIN, of New Orleans, called attention to the importance of examining all scalp wounds immediately after an injury, to determine whether or not fractures might be present, and to the need of an operation at any time that symptoms of cortical irritation were manifested, whether due to or suspected to be of traumatic origin. He reported three interesting cases, in one of which there had been an operation sixteen years after the injury. The man at the time of the operation was in such mental condition that he was not able to transact business and was a care to his family. He was relieved by an osteoplastic resection, and was so much benefited that he was able to resume business in a short time, and, although he had had several convulsions after the operation, his mind was perfectly clear and he felt that he had been greatly benefited. The third case was one of a child who had been struck in the head by a plowshare four years previously. The case had been given up as hopeless, the child presenting the most peculiar symptoms, absolutely unmanageable, and a constant care, with frequent convulsions both day and night. Removal of a segment of bone in this case at the seat of injury had resulted in perfect relief and the mental restoration of the child, who, although operated on four years ago, had never had any return of the trouble and had continued to improve.

**The Value of Intestinal Exclusion as a Surgical Procedure.**—Dr. JOHN YOUNG BROWN, of St. Louis, after discussing the various surgical methods in common use for the restoration of intestinal continuity following artificial anus done for the relief of gangrenous hernia, reported three interesting cases in which intestinal exclusion of the afferent and efferent bowel had been done, followed by end to end anastomosis.

The first case was one of strangulated umbilical hernia in which the cæcum, the appendix, and the ascending and transverse colon were found gangrenous in the sac. At the primary operation an artificial anus was made at the umbilical ring. Ten weeks after this operation the abdomen was opened through

a median incision, and bilateral exclusion of the ileum and descending colon was done, followed by direct anastomosis of the ileum to the sigmoid, anastomosis being made with the Murphy button. The patient made an excellent recovery, and the prolapsed bowel, which remained after intestinal continuity had been restored, was removed later under cocaine anæsthesia by the clamp and cautery.

The second case was one in which artificial anus was made for a gangrenous inguinal hernia of the right side, the anus being made at the hernial site. In this case a similar procedure was undertaken. The abdomen was opened through the right rectus, the afferent and efferent loop of ileum excluded, and end to end anastomosis made with a button. The result was exceedingly satisfactory.

The third case was one in which typhlotomy was done through a gridiron incision, and at the same time the entire large bowel was excluded, except the cæcum. The operation was performed after faithful and unsuccessful efforts had been made to relieve multiple fistulæ and ischiorectal sinuses, with necrosis of the coccyx. It was deemed advisable to turn the fæcal current, and this method was resorted to. The turning of the fæcal current resulted in healing of the old sinuses. The intestinal continuity was later restored by exclusion of the cæcum and lateral anastomosis of the ileum to the ascending colon, the last operation being done through an abdominal incision through the right rectus muscle.

In each of the cases reported the various steps of the operation were carried out without difficulty, and the results were all that could be wished.

Attention was called to the fact that in cases where artificial anus was made for the relief of the gangrenous hernia, the irritation brought about by the constant fæcal leakage produced a dense contraction of the scar, which resulted in complete relief of the hernia. By opening the abdomen through an incision away from the original wound, the bowel could be excluded and end to end anastomosis performed with perfect ease, and without impairing the repair work done by Nature in relieving the hernia.

The paper concluded with a strong plea for the employment of intestinal exclusion in the treatment of this condition, the writer believing the operation to be safe, surgical, and satisfactory.

**Hæmaturia in Pregnancy.**—Dr. EDWARD A. BALLOCH, of Washington, surveyed the literature of so called idiopathic, or essential, hæmaturia, or hæmaturia without demonstrable cause. He showed that most of these cases were in the older literature, and that modern research tended toward skepticism as to the possibility of renal hæmaturia without some lesion in the kidney. The two principle theories of causation, the angioneurotic and the chronic nephritis theory, were discussed, and the conclusion was arrived at that the latter had the weight of evidence in its favor.

The influence of nephrectomy upon subsequent pregnancy was discussed. As a case reported was the second instance in the writer's experience where an uneventful pregnancy had followed nephrectomy, he did not consider that the loss of one kidney had much effect upon subsequent pregnancy.

The cystoscope and urethral catheter were essential to a proper diagnosis. The existence and func-

tional capacity of a second kidney should be demonstrated before operative measures were practised. In the matter of treatment, the author considered that an analysis of reported cases showed that equally good results had followed decapsulation and nephrotomy as had followed nephrectomy. He advised the following order of procedure: 1. Injection of adrenalin solution into the pelvis of the kidney. 2. Nephrotomy or decapsulation. 3. Nephrectomy. Nephrectomy should be resorted to only in cases intractable to other measures, as it was essential to save as much of the kidney structure as possible.

**The Sensitive Short Uterosacral Ligament; Its Clinical Significance and Treatment.**—Dr. EDWARD J. ILL, of Newark, N. J., drew attention to the sensitive short uterosacral ligament as a pathological entity. Schultz and Burrage had written of the condition long before this. Schultz gave no special advice as to treatment, while Burrage recommended incision of the ligament through an abdominal section. Ovaries had been sacrificed under a false apprehension. The condition should not be confounded with intraperitoneal adhesions or with shortening of the base of the broad ligament due to scars resulting from puerperal injuries. Outside of the acute pelvic exudate, the writer knew of no condition so painful on pressure as the short and sensitive uterosacral ligament. During the last twelve years 5 per cent. of all his operative gynecological patients had suffered with a short and sensitive uterosacral ligament. When but one ligament was diseased, it occurred in 73 per cent. on the left side. The disease might be congenital or acquired either in childhood or during active sexual life. Because of the short ligament, fixation of the uterus resulted. The circulation of the organ became impaired. Catarrhal and metritic changes resulted in menstrual disturbances. In the acquired case, when but one ligament was short and sensitive, the pain was commonly referred to the sacroiliac synchondrosis or the iliac region of that side. Menstrual pain seemed to be common to all, and was produced by metritic and endometritic changes. The neurasthenic cases offered a bad prognosis. Sterility was a frequent symptom, and abortion sometimes resulted from a very short ligament. The objective effects, when both ligaments were shortened, were to elevate the uterus and drag it into the hollow of the sacrum. Its mobility was much impaired. When one ligament was short, the uterus was elevated and displaced to the side of the short ligament and retroposed. The short ligament stood out sharply when the cervix was drawn forward and downward. Great pain resulted from such a procedure. The prognosis was bad for those who came from a neurotic family or where from long standing conditions the resulting pathological changes had become incurable. The operation suggested by the writer consisted of a most thorough stretching of the tense and sensitive uterosacral ligaments, while the patient was under profound anæsthesia, until the uterus became freely movable. A free dilatation of the uterus with graduated steel sounds, curettage, etc., should be added.

**Cyst of the Pancreas.**—Dr. RICHARD HALL, of Cincinnati, said that true cysts of the pancreas were retroperitoneal tumors, while pseudocysts were intraperitoneal accumulations of fluid. Indigestion,

the literature, the tail of the pancreas was the favorite situation for the development of these cysts. The diagnosis of pancreatic cysts should be based upon the character of the contents of the tumor rather than upon the supposed demonstration of an anatomical connection. The author reported a case of cyst of the pancreas in a woman, forty-two years of age, upon whom he had operated successfully.

**Transperitoneal Ureterotomy for Ureteral Calculus.**—Dr. GERRY R. HOLDEN, of Jacksonville, Fla., reported a case in which he had resorted to this operation for the removal of a stone in the ureter. He pointed out the reasons why an abdominal extraperitoneal operation was impossible on account of the thick abdominal walls. He did not believe that transperitoneal ureterotomy for ureteral calculus was often the operation of election. He did believe, however, that it was the best operation when the stone was impacted at or just above the uterine artery, provided one was reasonably assured that infection was either mild or else absent altogether.

**The Inconsistencies of the Gauze Pack.**—Dr. HUBERT A. ROYSTER, of Raleigh, N. C., said we drained before we knew why we drained. A strip of gauze was simply a means of applying the law of capillary attraction. Rubber tube and tissue had been substituted, because the gauze so frequently failed to drain, acting as a successful stopper to the outlet. The one thing to be desired was patency of the wound, but there could be no more efficient plug than the stereotyped gauze packing. When intended for a drain, gauze should be inserted after the manner of a lamp wick; when used for hæmorrhage, it should be packed in like wadding with a ramrod. There was a field for gauze in packing sinuses, fistulae, and granulating wounds, so that healing might take place slowly from the bottom. Some would persist in using gauze drains, and in the event of disaster would console themselves by believing that it was better to have drained and lost than never to have drained at all. The use of gauze to wall off septic matter in abdominal operations was fraught with danger and full of inconsistencies. The placing of large pads or rolls of gauze in the cavity necessitated a long incision and undue handling of the viscera, and almost always uninfected regions were in contact with pus soaked gauze. When one end of the gauze was soaked with pus, the other end would become soiled sooner or later. The common practice was to push the gauze packs through pus collections into healthy parts or to wall off around localized abscesses with pads, which soon became saturated with purulent products. Exposure of the peritoneum to gauze soaked with pus was just as dangerous as the presence of pus itself among the intestines. A glaring inconsistency was seen in the removal of the packs with contaminated hands. The surgeon should resolve, first, that he would employ gauze sensibly, if he could, and not at all, if he could not. Second, if the using of gauze "maketh our technique to offend, we will use no more gauze while the world standeth."

**Gunshot Wounds of the Abdomen.**—Dr. LE GRAND GUERRY, of Columbia, read a paper on this subject, in which he reported eight consecutive cases of gunshot wounds of the abdomen.

**Suppurative Phlegmonous Gastritis.**—Dr. J. WESLEY BOVÉE, of Washington, after going extensively into the literature of this subject, reported a case of circumscribed suppurative phlegmonous gastritis in which he had resorted to gastrostomy. The case was complicated by pregnancy of six months and abortion. Mrs. T., white, thirty-six years of age, who had had seven children, followed in 1895 by a miscarriage, was admitted to the Columbia Hospital on October 6, 1907. She had suffered from pain in the epigastric region for several years, which was usually relieved by taking food. Her last menstrual period occurred on April 13, 1907, and she considered herself pregnant. On October 3d she ate heartily of boiled cabbage for dinner and crabs late at night. In the night she was attacked by severe pain in the region of the stomach. Morphine was given for the pain. On the following day the pain continued and vomiting set in. An attempt to move the bowels by enemata and cathartics was unavailing. The temperature was elevated, ranging from 99.5° to 101.5° F. The pulse was rapid and weak. The next day croton oil was employed by the mouth, but the bowels failed to respond. The various remedies were not effective in relieving the pain, constipation, and vomiting. The vomited material was first solid and partially digested food. Later it was watery and frothy, changing to dark green. She was so enfeebled and appeared to be so ill that the attending physician secured an ambulance and took her to the hospital on Sunday night, as mentioned. No chill or sweat was experienced. Dr. Bovée saw her about 11 o'clock that night. At that time her pulse was thready and her countenance anxious in appearance. Examination under anaesthesia disclosed that the uterus extended to an inch above the umbilicus, and the epigastrium was distended, very tender, and tympanitic. A median line incision above the uterus was made. The intestinal loops were congested, but not adherent. The stomach was palpated. It was found to be fully three fourths of an inch thick at the middle of the greater curvature, gradually thinning toward the cardiac end. In the pyloric end and in front was a mass of nearly the size of a man's fist, that was soft, though not doughy, to the touch. This gradually thinned out toward the middle of the stomach. The stomach was opened at about its middle by a longitudinal incision of about three inches, and the mucosa inspected. To determine the nature of the enlargement more definitely, a separate short incision was made over it, when the nature of its contents was manifest. Gauze was passed around it and it was opened, and two to three ounces of grayish pus escaped. The long incision was closed and the pus cavity wiped out. A rubber tube was tightly sutured into it and brought out of the abdomen. A light gauze drain was packed about it. She was fed per rectum for twenty-one days. Five days after the operation liquids were given by the mouth, as salt solution by hypodermoclysis and liquids by the rectum did not quench her ravenous thirst. The following day the contents of the stomach came through the wound. A few days later solid food was given and the tube removed. Stomach contents ceased escaping in a few days.

On the eighth day with little effort she aborted, the fœtus living three hours. With the exception of infection of the abdominal incision, which required resuturing, she had made an uninterrupted recovery.

**Harmful Involution of the Appendix.**—Dr. ROBERT T. MORRIS, of New York, said that most cases of stomach and bowel trouble were not cases of stomach and bowel trouble. Normal involution of the appendix was often a harmful process and produced many of the symptoms ascribed to other organs. Bile tract adhesions, eye strain, loose kidney, and several pelvic conditions caused symptoms similar to the ones produced by involution of the appendix. The diagnosis was easily made by two features: First, a persistent or frequently recurring sense of discomfort in the appendix region. Second, supersensitiveness of the right lumbar ganglia. This latter point was of definite and constant diagnostic importance. To find the right lumbar ganglia, draw a line from the navel to the right anterior superior spine of the ilium. One inch and a half from the navel on this line would be found the diagnostic point on deep pressure. McBurney's point was six or eight inches away, at the other end of the line. McBurney's point had reference to acute inflammatory processes in the appendix itself. The point described by Dr. Morris had reference to reflex disturbances caused by the appendix. If the right lumbar ganglia alone were tender on pressure, the appendix alone was responsible for disturbances of the stomach and bowel that were ascribed to other causes. If the disturbance proceeded from some organ in the pelvis, both right and left lumbar ganglia were tender. If the disturbance proceeded from the bile tract or from eye strain or from some point above the navel, neither the right nor the left lumbar ganglia were tender.

Dr. Morris referred to the new era of physiological surgery, based upon the studies of Metchnikoff and Wright. The patient would be allowed to do most of the work in managing his infection, and the surgeon was to leave him with such a degree of normal resistance after an operation that he could elaborate his phagocytes and opsonins. He thought he stood alone in advocating the doctrine of the new era, but in a year or two more many surgeons would be upholding the doctrine. They would stop doing elaborate work in appendicitis cases with pus, for instance, and they would not fear spreading pus over the normal peritonæum, nor would they stop to remove the pus, provided they could operate quickly and with so little disturbance to the patient that he was left with his normal resistance unimpaired. The surgeon's function was merely to turn the tide of the battle between bacterium and phagocytes, and they left most of the work for the patient. That was the new principle. Instead of trying to remove the infection by surgery, the infection would be left to be removed by the patient physiologically after turning the tide of battle for him.

**The Surgery of the Heart and Pericardium.**—Dr. RUDOLPH MEYER, of New Orleans, described the recent advances in the surgery of these organs. According to statistics, the proportion of recoveries

after operations on the heart was 43.83 per cent. In 134 cases of suture there had been forty-nine recoveries. In eleven cases the heart had been exposed without suture, and five patients had recovered.

While the value of statistical conclusions must not be overrated, it might be safely concluded that heart wounds, far from being invariably fatal, gave three chances in four for survival long enough to permit of surgical intervention, one chance in ten to heal spontaneously, and one in two to be cured by surgery.

Further progress in cardiac surgery could be accomplished only by methods which would diminish three great factors in the mortality, namely, shock, hæmorrhage, and infection. The writer then discussed the most recent suggestions which gave promise of decided progress in at least these three directions: 1. The diminution of shock by simplifying the preliminary thoracotomy, which gave the operator free access to the pericardium and the heart. 2. Methods of hæmostasis which controlled the bleeding from the wounded heart itself, while the suture of the wound was accomplished. 3. Methods which would diminish the tendency to fatal postoperative infection (*a*) by proper attention to asepsis, usually neglected in emergencies; (*b*) by prophylactic drainage of the pericardium and pleura, and (*c*) by immediate or early obliteration of the pleural space and by the expanded lung to avoid the dead space left by the retracted lung in pneumothorax.

**The Present Status of Gastric Surgery.**—Dr. J. GARLAND SHERRILL, of Louisville, read a paper on this subject in which he reported three cases illustrating different conditions for which an operation might be done with the hope of materially benefiting the patient's condition.

*Case 1.*—A man, aged thirty-five years. Gastroenterostomy done for dilatation, which was causing great distress, with the result that the patient had been entirely relieved.

*Case 2.*—A man, aged fifty. He gave a history of gastric trouble extending over a period of three years and a half, with a diagnosis of ulcer of the stomach, with imperfect drainage. The operation in this case consisted of gastrectomy, or removal of the ulcer and the ulcer bearing area. The result in this case also was very good.

*Case 3.*—A woman gave a history of suffering from indigestion and various stomach disorders for a period of six years, with an interval of quiescence. She had had a number of hæmorrhages from the stomach, had lost in flesh, and began to show a cancerous cachexia. A diagnosis of ulcer of the stomach with contracture, probably beginning malignant change, was made. At the operation, which consisted of a gastroenterostomy, a cancerous nodular mass was found involving the lesser curvature of the stomach for three fourths of its length, and the central portion of the stomach, both anterior and posterior surfaces for several inches, and the left lobe of the liver, which was closely bound by the growth of the stomach. An anastomosis was made with difficulty, owing to the necessity of making it quite far to the left beyond the border of the upper

It was possible to complete the operation only after making an opening through the gastrocolic omentum in addition to the one through the transverse mesocolon, and bringing the intestine through both openings and the posterior wall of the stomach through the opening of the greater omentum and there making the anastomosis. After this was accomplished the operation was completed in the usual manner. The patient made a good recovery from the operation, obtained great relief from the gastric discomfort, and had been enabled to take nourishment by the stomach, which was not possible for some time previously. She had, however, an oedema of the feet, which made the hope of her final cure very small.

Officers were elected as follows: President, Dr. F. W. Parham, of New Orleans; vice presidents, Dr. Willis F. Westmoreland, of Atlanta, and Dr. Henry D. Fry, of Washington; treasurer, Dr. Stuart McGuire, of Richmond; secretary, Dr. William D. Haggard, of Nashville.

St. Louis was selected as the place for holding the next annual meeting, in 1908.

### Letters to the Editors.

#### VIVISECTION IN THE STATE OF NEW YORK.

*Medical Society of the State of New York, Committee on Experimental Medicine.*

64 MADISON AVENUE,  
NEW YORK, January 21, 1908.

To the Editors:

On April 8, 1907, the president of this society appointed twenty-four members thereof to be a committee on experimental medicine, in view of proposed legislation calculated to injure the progress of medicine by restricting experimentation.

As agitation in this direction has recently been renewed, in a very plausible form, the undersigned have been instructed by the said committee to send you the following copy of a preamble and resolution adopted at a meeting thereof held in New York, on January 15, 1908, and respectfully to request the publication thereof in the *New York Medical Journal*:

*Whereas*, in the State of New York a petition is being widely circulated among medical men for signature in favor of a proposed bill entitled An Act to Prevent Cruelty by Regulating Experiments on Living Animals; and

*Whereas*, the said bill contains in its provisions conditions which would probably seriously impair the progress of scientific medicine,

*Resolved*, that the Committee on Experimental Medicine of the Medical Society of the State of New York earnestly requests the members of the medical profession to refrain from signing the aforesaid petition, and urges any who may have signed the same by inadvertence to withdraw their signatures.

The present laws of this State relating to this subject have long proved adequate and satisfactory.

JOSEPH D. BERRY, M. D., chairman.  
JOHN G. CURTIS, M. D., secretary.

### Book Notices.

*Functional Nervous Disorders in Childhood.* By EDWARD G. GUTHRIE, M. A., M. D., F. R. C. P., Senior Physician to Paddington Green Children's Hospital, etc. London: Henry Frowde and Hodder & Stoughton, 1907. (Price, \$3.)

Dr. Guthrie has here collected, in a very presentable form, a series of lectures and addresses delivered by him at various times before learned societies and students at a postgraduate institution. Most of them have appeared before, but in the present volume, appearing as they do as a more coherent and controlled presentation, added weight is given to a number of papers which of themselves are full of suggestion and counsel. The neurotic child is father of the neurasthenic adult is the author's chief thesis, and it is his aim to develop a point of view with prophylaxis as its final justification.

There are twenty-one chapters, the titles of a few of which will outline the scope of the work. He speaks of the Effects of the Emotions on Health, Nervous System in Childhood, Types of Neurotic Subjects, Hypersensitiveness of Special Senses, Mental and Educational Overstrain, etc. Apart from a few chapters dealing with spasmodic asthma, tics, chorea, etc., the work is devoted entirely to a study of the nervous system in childhood in its purely functional aspects. It is a work much needed in the English tongue, and should be read by all, for all physicians are interested in building up a healthy stock. The functional disorders of the nervous system are bound to increase with the rapidly increasing complexities of social relations, and although adaptation is always at work, wear and tear and strain will claim their victims. Childhood is the time when better adjustments may be planned and dangers perhaps averted. Useful hints and suggestions are to be found in Dr. Guthrie's work.

#### BOOKS, PAMPHLETS, ETC., RECEIVED.

A Textbook on Uric Acid and its Congeners. With Special Reference to its Physical and Chemical Properties, its Metabolism, and Accumulation in the Organism. Together with the Disease Processes Arising Therefrom and Their Etiological Therapy. For Medical Students and Practitioners. By George Abner Gilbert, M. D., Member of Local, County, and State Medical Societies of Connecticut, etc. First Edition. Danbury, Conn.: The Danbury Medical Printing Company, 1907. Pp. 370.

Comparative Electrophysiology. A Physico-physiological Study. By Jagadis Chunder Bose, M. A., D. Sc., Professor, Presidency College, Calcutta. With Illustrations. New York, Bombay, and Calcutta: Longmans, Green, & Co., 1907. Pp. 760.

Medical Diagnosis. A Manual for Students and Practitioners. By Charles Lyman Greene, M. D., Professor of the Theory and Practice of Medicine in the University of Minnesota, etc. Second Edition, Revised, with Seven Colored Plates and Two Hundred and Forty-one Illustrations. Philadelphia: P. Blakiston's Son & Co., 1907. Pp. 691.

Transactions of the Fifth Annual Conference of State and Territorial Health Officers with the United States Public Health and Marine Hospital Service, held in Washington on May 29, 1907. Washington: Government Printing Office, 1907. Pp. 47.

An Introduction to the Study of the Infant's Stool. By Paul Selter, M. D., Solingen, Germany. Translated by Herbert M. Rich, B. L., M. D., Detroit, Mich. Detroit: The Detroit Medical Journal Company, 1907. Pp. 28. (Price, 30 cents.)

Sul processo de riparazione delle perdite di sostanza nelle cartilagini e pericordio. Per il Prof. Dott. Giulio Anzilotti, aiuto e libero docente di patologia chirurgica. Pisa: Orsolini-Prosperti, 1907. Pp. 38.

Anæmia in Puerto Rico. Report of the Permanent Commission for the Suppression of Uncinariasis in Puerto Rico for the Fiscal Year 1906-1907. Respectfully submitted to the Honorable Régis H. Post, Governor of Puerto Rico, September 30, 1907.

## Official News.

### Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon General, United States Public Health and Marine Hospital Service, during the week ending January 17, 1908:

Places.	Dates.	Cases.	Deaths.
California—San Francisco.....	Dec. 22-Jan. 10.....	6	0
Florida—Altamonte.....	Dec. 28-Jan. 10.....	1	0
Illinois—Danville.....	Dec. 28-Jan. 10.....	1	0
Illinois—Springfield.....	Dec. 28-Jan. 10.....	20	0
Indiana—Elkhart.....	Dec. 28-Jan. 10.....	1	0
Indiana—Muncie.....	Dec. 28-Jan. 10.....	1	0
Kansas—Kansas City.....	Dec. 28-Jan. 10.....	1	0
Kentucky—Covington.....	Dec. 28-Jan. 10.....	9	0
Louisiana—New Orleans.....	Dec. 28-Jan. 10.....	4	0
Massachusetts—Fall River.....	Dec. 28-Jan. 10.....	3	0
Michigan—Grand Rapids.....	Dec. 28-Jan. 10.....	1	0
Michigan—Saginaw.....	Dec. 21-28.....	3	0
Minnesota—Winona.....	Dec. 28-Jan. 10.....	4	0
Missouri—Kansas City.....	Dec. 28-Jan. 10.....	4	0
Missouri—St. Louis.....	Dec. 28-Jan. 10.....	2	0
Montana—Helena.....	Dec. 1-30.....	1	0
Nebraska—Nebraska City.....	Dec. 28-Jan. 10.....	1	0

### Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the seven days ending January 18, 1908:

BERRY, T. D., Passed Assistant Surgeon. Granted leave of absence for two days from January 1, 1908.

BROOKS, S. D., Surgeon. Directed to proceed to Randburg, Cal., for special temporary duty; upon completion of which to rejoin his station at Los Angeles, Cal.

CHAPIN, C. W., Assistant Surgeon. Relieved from duty at Detroit, Mich., and directed to proceed to Seattle, Wash., reporting to Passed Assistant Surgeon Cofer for special temporary duty.

CHENEY, E. L., Acting Assistant Surgeon. Granted leave of absence for fourteen days from January 31, 1908.

EARLE, B. H., Passed Assistant Surgeon. Granted leave of absence for fifteen days from January 14, 1908.

GOODMAN, F. S., Pharmacist. Relieved from duty at Cape Charles Quarantine Station and from temporary duty at Baltimore, Md., and directed to proceed to Tampa Bay Quarantine Station, reporting to the medical officer in command for duty and assignment to quarters.

GRAHAM, EARL A., Pharmacist. Directed to proceed to Stapleton, N. Y., reporting to the medical officer in command for duty and assignment to quarters.

KEEN, W. H., Pharmacist. Relieved from duty at Tampa Bay Quarantine Station and directed to proceed to Cape Charles Quarantine Station, reporting to the medical officer in command for duty and assignment to quarters.

RANSOM, S. A., Acting Assistant Surgeon. Excused from duty, without pay, for twelve days from December 5, 1907.

ROGERS, EDWARD, Pharmacist. Relieved from duty at Stapleton, N. Y., and directed to proceed to Fort Townsend, Wash., reporting to the medical officer in command for duty and assignment to quarters.

SPRATT, R. D., Assistant Surgeon. Granted an extension of leave of absence for two days; granted leave of absence for twenty-one days from January 14, 1908.

STEVENSON, J. W., Acting Assistant Surgeon. Excused from duty, without pay, for three months from January 6, 1908.

STONER, G. W., Surgeon. Granted leave of absence for three days from January 8, 1908, under paragraph 189, Service Regulations.

STUMP, F. A., Pharmacist. Directed to proceed to Chicago, Ill., reporting to the medical officer in command for duty and assignment to quarters.

THOMAS, A. M., Pharmacist. Directed to proceed to San Francisco Quarantine Station, reporting to the medical officer in command for duty and assignment to quarters.

#### Appointments

Karl H. Graham and Frank A. Stump were appointed pharmacists of the third class, January 10, 1908.

#### Reinstatement.

Mr. A. M. Thomas was reinstated as pharmacist of the third class in this Service, January 8, 1908.

#### Appointments Revoked.

The appointments of Linn Bradley and F. J. Perusse to be pharmacists of the third class have been revoked.

#### Board of Health.

A board of medical officers was convened to meet at Seattle, Wash., January 16, 1908, for the purpose of examining aliens suspected of having trachoma. Detail for the board: Passed Assistant Surgeon I. E. Coffey, chairman; Passed Assistant Surgeon M. J. Wynn, and Acting Assistant Surgeon I. R. Underwood, members.

### Army Intelligence:

Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending January 17, 1908:

BAKER, H. H., First Lieutenant and Assistant Surgeon. Will proceed to Columbus, Pa., to accept a detachment of recruits in Fort Meade, Cal.

BANKS, W. P., First Lieutenant and Assistant Surgeon. Will proceed to report on February 4, 1908, to Fort Meade, Cal., to accept a detachment of recruits in Fort Meade, Cal.

- Presidio of San Francisco, Cal., for examination for advancement.
- BLOMBERG, H. D., Captain and Assistant Surgeon. Ordered to Jefferson Barracks, Mo., for temporary duty.
- CRAIG, C. F., First Lieutenant and Assistant Surgeon. Will report in person on February 11, 1908, to Major W. D. Crosby, surgeon, president, examining board at the Army Medical Museum Building, Washington, D. C., for examination for advancement.
- GANDY, CHARLES M., Professor of Military Hygiene. Appointed a member of a board of medical officers to meet at West Point, N. Y., February 4, 1908, for physical examination of the cadets of the first class at the U. S. Military Academy.
- HANNER, J. W., Captain and Assistant Surgeon. Appointed a member of a board of medical officers to meet at West Point, N. Y., February 4, 1908, for physical examination of the cadets of the first class at the U. S. Military Academy.
- IVES, F. J., Major and Surgeon. Retired from active service at Fort McHenry, Md., and will proceed to San Francisco, Cal., taking transport to sail on or about March 5, 1908, for Philippine Islands.
- KEEFE, F. R., Major and Surgeon. Appointed a member of a board of officers, to meet at the General Hospital, Presidio of San Francisco, Cal., February 4, 1908, for examination of such officers of the Medical Department as may be ordered before it to determine their fitness for promotion or advancement.
- KENDALL, W. R., Major and Surgeon. Appointed a member of an Army retiring board, to meet at Fort Sam Houston, Texas, for examination of such officers as may be ordered before it.
- KENNEDY, J. M., Major and Surgeon. Appointed a member of a board of officers, to meet at the General Hospital, Presidio of San Francisco, Cal., February 4, 1908, for examination of such officers of the Medical Department as may be ordered before it to determine their fitness for promotion or advancement.
- MASON, C. F., Major and Surgeon. Appointed a member of a board of medical officers to meet at West Point, N. Y., February 4, 1908, for physical examination of the cadets of the first class at the U. S. Military Academy.
- NELSON, KENT, Captain and Assistant Surgeon. Relieved from duty at Fort McHenry, Md.; will proceed to San Francisco, Cal., and take transport to sail on or about March 5, 1908, for Philippine Islands.
- TORNEY, G. H., Lieutenant Colonel and Deputy Surgeon General. Appointed a member of a board of officers, to meet at the General Hospital, Presidio of San Francisco, Cal., February 4, 1908, for examination of such officers of the Medical Department as may be ordered before it to determine their fitness for promotion or advancement.
- WHALEY, A. M., First Lieutenant and Assistant Surgeon. Appointed a member of an Army retiring board, to meet at Fort Sam Houston, Texas, for examination of such officers as may be ordered before it.

### Navy Intelligence:

*Official list of changes in the medical corps of the United States Navy for the week ending January 18, 1908:*

- ANGWIN, W. A., Passed Assistant Surgeon. Detached from the Naval Hospital, Norfolk, Va., and ordered to the *Philadelphia*.
- BAGG, C. P., Surgeon. Detached from the *Philadelphia* and ordered to command the Naval Hospital, Puget Sound, Wash., and to additional duty at that yard.
- BIDDLE, C., Surgeon. Ordered to duty at the marine recruiting station, Philadelphia, Pa., and to additional duty in attendance on officers not otherwise provided with medical aid in that city.
- CATHER, D. C., Assistant Surgeon. Detached from the naval training station, San Francisco, Cal., and ordered to the *Lancaster*.
- DE LANCY, C. H., Surgeon. Detached from the naval recruiting station, Chattanooga, Tenn., and ordered to the navy yard, New York, N. Y.
- DENNIS, J. B., Surgeon. Detached from the Naval Hospital, Puget Sound, Wash., and ordered to the *South Dakota*.
- DUNBAR, A. W., Surgeon. Detached from the *California* and ordered to the *Relief*.

- JACOBSON, L. C., Acting Assistant Surgeon. Ordered to the Naval Hospital, Norfolk, Va.
- ORVIS, R. T., Surgeon. Ordered to the naval recruiting station, St. Louis, Mo.
- PARKER, E. G., Surgeon. Detached from the Naval Hospital, New York, N. Y., and ordered to the *California*.
- RUSSELL, A. C. H., Surgeon. Detached from the naval torpedo station, Newport, R. I., and ordered to the naval recruiting station, Chattanooga, Tenn.
- SPEAR, J. C., Medical Director, retired. Detached from duty at the marine recruiting station, Philadelphia, Pa., and ordered home.
- VERNER, W. W., Passed Assistant Surgeon. Detached from the naval recruiting station, St. Louis, Mo., and ordered to the naval training station, San Francisco, Cal.

## Births, Marriages, and Deaths.

### Born.

- O'DONNELL.—In Detroit, Michigan, on Sunday, January 12th, to Dr. D. H. O'Donnell and Mrs. O'Donnell, twin daughters.

### Married.

- ALLEN—HASKELL.—In Savannah, Georgia, on Wednesday, January 8th, Dr. Frederick Olcott Allen, of Philadelphia, and Miss Sallie Owens Haskell.
- BASTEIN—SHECKELS.—In Washington, D. C., on Wednesday, January 8th, Dr. F. E. Bastein and Miss Edna Sheckels.
- HARRINGTON—ELIOT.—In Washington, D. C., on Thursday, January 9th, Dr. Francis Edward Harrington and Miss Maye Llewellyn Eliot.
- KIRK—LAMBERT.—In Kingston, Ontario, Canada, on Wednesday, January 15th, Dr. F. James Kirk, of Brooklyn, and Mrs. A. E. Lambert.
- PHILLIPS—HYDE.—In Boston, on Saturday, January 11th, Dr. John C. Phillips and Miss Eleanor Hyde.
- RICHMOND—RICE.—In Everett, Massachusetts, on Thursday, January 9th, Dr. Fred M. Richmond and Miss M. Marion Rice.
- WILLIAMS—FORD.—In New York, on Saturday, January 18th, Dr. Linsly R. Williams and Mrs. Grace Kidder Ford.

### Died.

- ATKINS.—In Denver, Colorado, on Wednesday, January 8th, Dr. Edward Atkins.
- BANKS.—In Columbia, Mississippi, on Thursday, January 9th, Dr. M. L. Banks, aged seventy-six years.
- BEAUCHAMP.—In Lawton, Oklahoma, on Wednesday, January 15th, Dr. F. D. Beauchamp.
- COFFEY.—In New York, on Friday, January 17th, Dr. Joseph Coffey, aged forty-eight years.
- DARRALL.—In Washington, D. C., on Wednesday, January 1st, Dr. Chester B. Darrall.
- GAHRER.—In Brooklyn, on Monday, January 13th, Dr. Robert G. Gahrer, aged sixty-three years.
- HAINES.—In Philadelphia, on Thursday, January 9th, Dr. Hannah Rodman Haines, aged sixty-four years.
- HEBB.—In Randallstown, Baltimore County, Maryland, on Friday, January 10th, Dr. Henry J. Hebb, aged sixty-six years.
- KNIGHT.—In Toronto, Ontario, Canada, on Monday, January 13th, Dr. John Alexander Knight.
- MARILL.—In Poughkeepsie, New York, on Tuesday, January 14th, Dr. Joaquim Marill, aged seventy-three years.
- MURPHY.—In Chelsea, Massachusetts, on Sunday, January 12th, Dr. Stephen N. Murphy, aged thirty-five years.
- POMEROY.—In Springfield, Massachusetts, on Saturday, January 11th, Dr. Stephen F. Pomeroy, aged eighty years.
- ROOCH.—In St. Louis, Missouri, on Monday, January 13th, Dr. August Rooch, aged eighty years.
- SPARROW.—In Baltimore, Maryland, on Tuesday, January 14th, Dr. Louis Griffith Sparrow, aged seventy-nine years.
- STONE.—In Richmond, Virginia, on Thursday, January 9th, Dr. George L. Stone, aged sixty-three years.
- VICTORIA.—In New York, on Saturday, January 11th, Dr. José Lopez de Victoria, aged forty-two years.
- WINTERS.—In Silverton, Colorado, on Tuesday, January 14th, Dr. William R. Winters, aged fifty-four years.

### CARCINOMATOSIS OF THE MENINGES.

*Presentation of a Case of Carcinomatosis of the Meninges, with a Consideration of the Diagnosis of Multiple Carcinomatosis, Tuberculosis of the Nervous System, Disseminated Syphilis, and Multiple Sclerosis.*

By D. J. MCCARTHY, M. D.,  
Philadelphia,

Professor of Medical Jurisprudence, University of Pennsylvania.

AND

MILTON K. MEYERS, M. D.,  
Philadelphia,

Voluntary Associate, Pepper Laboratory.

(From the William Pepper Clinical Laboratory. Phoebe A. Hearst Foundation.)

The case which forms the subject matter of this paper is worthy of record not only on account of the rarity of the condition present, but also because the mistake in diagnosis, made after a careful clinical study, may be of some value in the consideration of similar cases.

Multiple secondary carcinomatosis of the nervous system limited to the meninges is a rare condition. Only eleven cases were discovered after a careful search of the literature. In all of the four cases reported by Siefert (1) there was a primary tumor of the brain. In the two cases of Scanzoni (2) tumors of the brain were secondary to carcinoma elsewhere, and the meningeal infiltration took its origin from these. In the case of Lilienfeld and Benda (3) the meninges of the cord were alone affected.

In some respects our case of secondary carcinomatosis localized to the meninges is unique. Scholz (4), it is true, under the title of meningitis carcinomatosa, reports two cases diagnosed as meningitis, in one of which the clinical diagnosis was substantiated by spinal puncture. Westenhöffer (5) reports a similar case of carcinomatous meningitis (confirmed by autopsy) where colon bacilli were found in the cerebrospinal fluid during life, and after death in the bloodvessels of the pia and dura. In only one of Scholz's cases is there mention of the involvement of the spinal cord or its meninges. In the other case the spinal meninges were involved, but no mention is made of spinal roots or ganglia, and the histological report is meagre. Although Scholz does not mention specifically the presence of collections of leucocytes, the case was reported as meningitis carcinomatosa, which Siefert had previously distinguished from simple meningeal carcinomatosis, in which signs of inflammation were absent. In Scholz's and in Westenhöffer's cases, however, the membranes were tense, the bloodvessels were highly injected, and the pia infiltrated with turbid exudate

showing here and there traces of blood or clots. On post mortem examination the conditions could not be distinguished from simple meningitis.

Of Siefert's cases, one was a case of meningitis carcinomatosa. Of the others, one shows the membranes adherent to the brain substance at the site of the tumor. Very careful histological examination showed that the meninges were extensively involved. Hemorrhages and collections of leucocytes were seen. There was penetration of the brain substance by the columns of cells. In the second case the meningeal changes in the brain were not extensively studied, but those of the spinal cord showed the presence of collections of leucocytes and hemorrhages in addition to the carcinomatosis. In the case of Lilienfeld and Benda there was oedema of the membranes of the brain, infiltration of the spinal meninges, invasion of the periphery of the cord by carcinoma, and involvement of the roots and of several cranial nerves. In the cases of Scanzoni the meninges of the cord were also principally involved.

The following case reported at the May meeting, 1907, of the Association of American Physicians, by Dr. Peabody, is evidently a case very similar to the one here reported, and the only case we have been able to find at all similar to it. In reporting this case, Dr. Peabody called attention to the case here reported from an abstract of the history and clinical findings published in the transactions of the Philadelphia Neurological Society, three years ago, at which the brain was shown as a card specimen.

Dr. Peabody's case was a woman forty-three years old. Four years after the removal of the breast for carcinoma she developed pains, especially marked in the lower extremities, back, and shoulders. The pain was severe and the prostration became intense. Electrical reactions were normal. Treatment did not relieve her pains. She slept but little and gradually became mildly delirious. Lumbar puncture gave normal fluid. About a week before death she was attacked with partial ptosis of the right eye, partial paralysis of the muscles of the right side of the face, weakness of the right palate muscles, and partial deafness of the right ear. Diplopia was present in part of the field of vision. Pain in thighs and legs persisted, and pain was noted in the lumbosacral region on attempting to sit upright and on pressure. There was no other alteration of sensation. The eye grounds were normal. Urination and defecation became involuntary. The muscles of deglutition gradually became impaired, and water regurgitated through the nose. She died of asphyxia of the lungs three weeks after coming under observation.

Autopsy showed metastatic carcinoma of the thyroid, of one suprarenal gland, and of one lung.

wall of an old cyst in cerebellum, numerous small metastatic growths in the pia of pons and medulla, without lesion of the pons or the medulla. There was diffuse infiltration, with carcinoma of the perineural lymph sheaths of one trunk nerve of the

FIG. 1. Left parietal lobe, showing primary carcinomata and their relation to the cerebral veins.

cauda equina, and in one place the nerve trunk itself was similarly invaded. The pia covering the cord showed small metastatic growths. This case has since been reported in the literature (6).

In the case about to be presented it will be noticed upon reading the pathological report that the lesions were small pin point, and closely scattered like small grains of sand over the surface of the brain and cord.

**CASE.**—M. S., colored, age thirty-eight, by occupation cook, was admitted to the woman's nervous wards of the Philadelphia General Hospital, April 9, 1905. She complained of pains in both lower extremities and in the lumbar regions. At times the pains extended into the left chest.

**Family history:** Mother died at the age of eighty-one and father at the age of ninety-three, of senility. One brother died of typhoid fever at ten years of age. The cause of death of one sister at eight years was unknown to the patient. One sister died at the age of forty-six, of asthma, and one at fifty, of heart disease. There was no history of tuberculosis in the family.

**Previous history:** There was a history of the usual diseases of childhood, malaria at thirteen, nettle rash at nineteen, acute articular rheumatism at thirty; she had been subject to sick headaches for a long time, and had complained of cough throughout the winter.

**History of present illness:** Three months ago the present trouble began with pain in the right elbow and hand, and headaches in the occipital and temporal regions. Two days later the pain extended to the left hand. Several days later she complained of pain in the lumbar region and in both lower extremities. There was a persistent cough associated with pain in the chest and back.

The examination of the patient on April 9, 1905, revealed a well developed, well nourished negroess. Motion was relatively normal over the entire body.

**Cranial nerves:** Examination of the cranial nerves revealed no abnormal symptoms in their distribution, with the

exception that the right pupil reacted sluggishly to light. The right knee jerk was absent; the left knee jerk was present, but diminished. The Achilles jerk was present on both sides and decreased. There was no ankle clonus and no Babinski reflex. There was flexion of all the toes to plantar irritation. The superficial abdominal reflexes were normal. The biceps and triceps jerk of both upper extremities were exaggerated.

Examination of the chest revealed impaired resonance over the left chest posteriorly, below the angle of the scapula. Over this area there was bronchovesicular breathing and moist râles, more marked on expiration. Vocal and tactile fremitus were increased over the same area.

April 15, 1905. There was severe pain in both legs and over the lumbar region.

April 29, 1905. An ophthalmoscopic examination was made by Dr. Sweet. The left pupil reacted promptly, the right sluggishly. The eye grounds were normal, the nerves were of good color. The ocular movements were unimpaired. The visual fields, roughly tested, were normal.

May 10, 1905. The pain in the legs still persisted. There was a sixth nerve palsy on the left side, and some hyperaesthesia of the chest posteriorly. There was no Kernig's sign on either side. The muscles of the left leg were more flabby than those of the right. While there was still flexion of the toes to plantar irritation on the right side, on the left side there was a well defined Babinski reflex.

May 15, 1905. The patient was only semiconscious. There was partial ptosis of both eyes, and she was unable to completely close the right eye. Attempts to swallow milk resulted in choking spells. In addition to the physical signs, there were some moist râles at the base of the right lung.

May 17, 1905. There was almost complete facial palsy on the right side, in both the upper and lower distribution of the nerve. The right eye was held in a third nerve paralytic position with marked dilatation of the pupil. There was marked ptosis of both sides. The exit points of both nerves were sensitive to pressure on both sides, with a well defined paralysis in the distribution of the fifth nerve on the left side. There was a slight Kernig's sign on the right side, but none on the left.

The last examination of the urine, made on May 17, 1905, showed specific gravity of 1.024, an acid reaction, and a slight trace of albumin. On microscopic examination, a few red blood corpuscles, a few leucocytes, a number of hyaline casts, and cylindroids were found.

**Pathological Report (Dr. Funke):** Chronic pleurisy, hemorrhagic infarct of the lung, carcinoma of the lung

FIG. 2. Extension of primary tumor of meninges of brain, and extension into the cortex.

(primary), chronic diffuse nephritis, secondary carcinoma of the liver, primary carcinoma of the pancreas.

The heart, spleen, kidneys, suprarenal bodies, and other organs not mentioned in detail, showed nothing abnormal.

The left lung weighed 530 grammes. Its upper lobe crepitated throughout and was pinkish red in color with black mottlings on its anterior surface. Only a slight oedema

was present. At the apex of the upper lobe crepitation was still perceptible, while in the remainder of the lobe crepitation was absent, and a dull note of percussion was elicited.

On section, a cavity measuring 1.5x2 cm. in diameter was found in the centre of this lobe. Its wall was grayish white, showing a granular substance. Around the cavity was a consolidated area made up of quite firm, confluent nodules, grayish white in color.

The left lobe of the liver contained a nodule 3 cm. in diameter. This reached the external surface and projects. The centre of the nodule was yellowish gray and granular. The periphery was granular and pinkish gray in color. To the right of this was a similar nodule.

On the upper surface of the pancreas were two nodules each measuring one and a half cm. in diameter. They were firm and were cut with resistance. The cut surfaces were grayish pink in color. They were apparently associated with the pancreas, possibly having taken origin from that structure. These nodules rested directly below the

columnar type of epithelial cells arranged in cell nests, and having the appearance of a carcinoma. The nests of cells were extended in an irregular way into the brain tissues, without, however, producing any degeneration of the underlying white matter as seen by the Weigert and iron hæmatoxylin stains. The cells were of a columnar type with an irregular deeply staining nuclei, and had the appearance of epithelial origin. Sections of the cortex stained by Mallory's connective tissue stain showed the fibres of connective tissue beginning about the bloodvessels and extending between, but not into, the alveoli.

There was no degeneration of the spinal cord by the sheath stains.

Hæmatoxylin eosin method: The main changes noted by this method were seen in the meninges; the tubercles scattered here and there over the spinal cord in an irregular fashion, noted in the gross examination, did not follow any regular distribution. They were widely distributed, not only over the meninges, but were also seen on the spinal roots. The sixth cervical segment of the spinal

FIG. 3.—Carcinomatous infiltration of meninges with secondary carcinoma of spinal, posterior root.

nodules described in the liver. Similar growths were found along the course of the portal vein.

The uterus showed a large, subserous fibroid arising from the right lateral surface a few cm. from the superior border of the fundus. The left ovary showed cysts.

The brain, gross examination: The entire brain was covered with minute white areas varying in size from a pin point to a pin head. These areas were most frequent along the course of the bloodvessels, and occurred in scattered points over the entire meninges. They were most marked and occurred in the greatest numbers over the base of the brain, and especially in the interpeduncular spaces.

Spinal cord.—The same condition was present over the spinal meninges, and most marked over the cervical enlargement. There was a tumor mass the size of a split pea on the tenth dorsal root. The second and third spinal ganglia were increased to the size of a small bean (5x7 mm.), were of hard consistency, and protruded as tumor masses on the inner side of the dura. The same milky tumor formation was present on the inner surface of the dura as far down as the midthoracic area.

Microscopic examination: Cerebral cortex.—The tubercles of the cerebral meninges were composed of a reticulum of connective tissue containing large masses of a

cord, for instance, showed a tumor mass in the meninges just within the left posterior spinal root and infiltrating it and extending to the posterior median fissure. There was also a milky tumor infiltration of the anterior root of the opposite side. The axis cylinders of the roots presented a swollen appearance, caused by infiltration of the roots by irregular shaped cells about the size of polynuclear leucocytes. These cells had deeply staining nuclei. The nucleus varied greatly in size, but in the main made up a relatively small portion of the cell area. Many of the cells had a circular, clear, unstained area in the protoplasm presenting a vacuolar appearance. These cells were held in alveolar spaces between the nerve fibres, but presented nothing regular in their arrangement. In the tumor infiltration of the meninges, the same microscopic appearance was seen in the centre, but towards the periphery there was a distinct cell nest arrangement. The cells here took a distinctly columnar type, having much the appearance of cells in adenocarcinoma, composed of columnar cells.

In the sections stained by Mallory's connective tissue stain there was no infiltration of the connective tissue fibrils between the cells. The tumor tissue was surprisingly free from connective tissue. A small tumor mass the size

of a split pea noted before, on the eleventh dorsal root, completely surrounded the root, but had a well defined capsule, over which bands of connective tissue extended into the interior, somewhat after the manner of a lymph gland.

In the alveolar space formed by the connective tissue, groups of columnar cells were seen here and there, following the same arrangement as described before. The degenerated and infiltrated root occupied the centre of the tumor mass. As one approached the centre of the tumor, the columnar shape and acinus arrangement of the cells was lost. The cells were grouped in an irregular way within the connective tissue. The connective tissue fibrils did not penetrate between the cells. In the lumbar enlargement the tumor infiltration completely surrounded the spinal cord and had the same microscopic picture as that seen in the cervical enlargement. The cord was indented by the pressure of the tumor mass, but there was no true infiltration of the white substance of the cord.

Sections stained by the Van Geisen method added nothing to that described by the other methods.

Marchi method: There was a recent marked secondary degeneration in the posterior columns of root origin. There was also some degeneration of the direct pyramidal tract of the left side, and a few scattered dots here and there in the right crossed pyramidal tract. There was a degeneration in both crossed pyramidal tracts and also in the posterior column. There was a degeneration of the posterior roots and a slight degeneration in the direct pyramidal tracts. The same was true of the dorsal cord.

Nissl method: In sections from the dorsal cord and lumbar spinal cord the majority of the ganglion cells of the anterior horn were in an advanced state of chromatolysis. Only a few of the cells even approached a normal appearance. In the cervical enlargement, many of the cells were degenerated. There was a much larger proportion of normal cells than in the cervical or dorsal cord.

Spinal Ganglia.—The nerves in the ganglion cells had entirely disappeared. There was also marked degeneration of the nerve fibres. The entire ganglia had been transferred into a mass composed of a reticulum of connective tissue, between which were arranged long rows of a columnar type of cell. In many of the alveolar spaces the cells had taken a more irregular arrangement, as already noted in the meninges.

#### *Pathological Discussion.*

The gross appearance of the brain when removed at autopsy, studded closely as it was with small tubercles, gave the impression at the first glance of a syphilitic meningitis. The more careful examination and the finding of the tumor masses in the other viscera led to a correct diagnosis. The microscopical examination presented a typical picture of carcinoma (see Fig. 2). The involvement of the cortex was unquestionably an extension from the meninges, and was more a displacement of the cortex, and could, in no sense, be considered a true infiltration.

Involvement of the spinal roots is not an uncommon condition, but involvement of the spinal ganglia is relatively rare. We have not been able to find a case in which this condition has been definitely stated. The pain in the extremities was probably the result of the tumor infiltration of the spinal ganglia and involvement of the roots.

The peripheral nerves and muscles were not examined.

The involvement of the cranial nerves is explained by the presence of miliary carcinomata in the piaarachnoid, surrounding their points of exit. There are no tumor masses on the nerves themselves.

#### *Clinical Remarks.*

A diagnosis of cerebrospinal syphilis was made in this case, in spite of the fact that the patient presented no history of syphilis. This negative symp-

tom, if it can be so called, was not given its proper value. This is not a matter of surprise when there is taken into consideration the difficulty in securing a positive history of syphilis, even when the patient is aware of it, and, what is more frequently the case in the class of patients under discussion, who either never knew or had forgotten such a "trivial matter." It should be remembered, however, when the diagnosis is under discussion that too much importance cannot be given to the elements of a carefully taken history. Ten years of constant effort has not sufficed to eliminate the Blockley mental attitude as to the presumption of syphilis in the diagnosis of a doubtful case, quite irrespective of the history. As an undergraduate student, resident physician, and assistant physician in the wards of the Philadelphia General Hospital, an atmosphere of syphilis of the nervous system in the diagnosis of obscure cases with multiple manifestations always led unconsciously to a presumption in its favor.

Multiple syphilis of the nervous system is not now, nor was it then, a very frequent condition. By this is meant lesions of the nervous system presenting the histological characteristics of syphilis. Scleroses, low grade inflammatory processes, and tract degenerations are present in large numbers, but it remains to be proved how frequently these are due to syphilis. *Tabes dorsalis*, conceded to be a parasymphilitic disease, does not present the histological lesions of syphilis, and is rarely associated with syphilitic lesions elsewhere in the body. *Tabes*, however, is diagnosed as such, and not as cerebrospinal syphilis.

In an extensive collection of brains and spinal cords, obtained for the most part from the Philadelphia General Hospital, multiple cerebrospinal syphilis is present in only a very small percentage.

It should be remembered in this connection that tuberculosis presents the multiple lesions of the nervous system similar in their character and distribution to those seen in syphilis. Lesions of multiple sclerosis, being widely distributed, not only present the multiple symptom group seen in syphilis, but the reverse may also be true—i. e., disseminated syphilis may present the classic clinical picture of multiple sclerosis. Oppenheim (7), and more recently Spiller and Camp (8), have written on this subject. In a paper recently published by Dr. C. W. Burr (9), a case of disseminated syphilis presenting the clinical picture of multiple sclerosis was reported, together with a discussion of the diagnosis of the two conditions.

It is conceded that a distinctive diagnosis between some types of multiple sclerosis and disseminated syphilis is impossible. The importance, therefore, of paying attention to a history of syphilis in order to prevent a mistake in diagnosis is evident. It will be seen from the clinical history, as given, and the clinical diagnosis that tuberculosis of the lungs was diagnosed. At autopsy, a cavity surrounded by epithelial type of tumor formation was discovered. In the absence of a history of syphilis, a natural presumption should have been in favor of multiple tuberculosis of the nervous system. Had this patient presented herself at my service, at the Phipps Institute, such a diagnosis would have been undoubtedly made, but the Blockley atmosphere in-

terfered with such a simple logical conclusion. An important question in this discussion, however, is why a diagnosis of secondary carcinomatosis of the nervous system was not made. The patient was thirty-four years old and in good condition. There was no cachexia. A careful examination of the different viscera showed no other lesions than impaired resonance over the left chest posteriorly, below the angle of the scapula; expiratory râles in the right axillary regions and at the base of both lungs; in the left axillary regions, an area about three inches in diameter, over which bronchovesicular breathing could be heard; increase in the vocal and tactile fremitus over the left lung posteriorly. Urinary examination showed some albumin and hyaline casts, but no other evidence of kidney insufficiency. The primary growth in the liver and the secondary growth were too small to give physical evidence of their existence. There was therefore no evidence of the presence of carcinoma, and it is questionable whether such a diagnosis of either the hepatic or pancreatic lesions was possible.

The predominating symptom on admission was pain in the lower extremities. The knee jerks were absent. On the following day, the left knee jerk was present. The right pupil reacted sluggishly to light. On admission, there was pain in the lower extremities, with headaches from three months previous. One month after admission, and nine days previous to death of patient, she first began to show cerebral symptoms. These began with affection of the sixth nerve on the left side, and after a few days were followed by an affection of both third nerves. On the following day the seventh nerve on the right side became affected, with an almost similar affection of the fifth nerve on the left side. On the day before her death, the difficulty of swallowing indicated an involvement of the ninth or tenth nerves. One week previous to her death there was a progressively developing stupor. Such a group of symptoms, with their progress, irregular distribution and development, indicated multiple lesions affecting first the spinal cord and later the brain. For this reason and for no other was the diagnosis of syphilis of the nervous system made.

In a patient presenting symptoms with an evident carcinoma elsewhere in the body, or with a history or evidence of its removal, the diagnosis of multiple secondary carcinomatosis of the nervous system could be made. A frank, active tuberculosis elsewhere in the body would lead to the diagnosis of tuberculosis of the nervous system. The history of syphilis, or distinct evidence of syphilis elsewhere in the body, would lead to a diagnosis of cerebrospinal syphilis. The history of the case with the rapid development of cerebral symptoms such a short time before death would practically exclude multiple sclerosis.

**Optic Nerve Involvement.**—Optic neuritis is found in 80 to 90 per cent. (Oppenheim, 10) of cases of brain tumor and in 15.5 per cent. of cases of meningitis (Uhthoff, 11). The absence of any optic nerve involvement, at least within a reasonable time before death, may be considered as an indication of a lack of extensive intracranial pressure.

The presence of Kernig's symptom in this case is a matter of some interest. The general impres-

sion among clinicians, and especially among pædiatrists, is that Kernig's symptom is diagnostic of meningitis. Kernig (12) in his original contribution reports thirteen cases of cerebrospinal (infectious) meningitis, one case of tuberculous meningitis, and one case of purulent cerebral meningitis, with chronic parenchymatous nephritis, all of which showed Kernig's symptom. He regrets that he had not been able to study it in the transitory meningitis that may usher in typhoid fever, typhus fever, and recurring fever. He also reports it present in six other cases, on all of which autopsy was performed. These were edema of the pia of obscure origin; hæmorrhagic pachymeningitis with intermeningeal bleeding; circumscribed pachymeningitis and leptomeningitis, and thrombosis of the petrosal sinus, secondary to caries of the petrous bone; growth of the dura to the skull and chronic leptomeningitis accompanying carcinoma of the brain; slight hæmorrhagic meningitis with hæmorrhage into the ventricle; slight general hyperæmia of the pia (questionably tuberculous). On the first day that the last patient was observed there was no contracture of the knees; on the second, however, the sign was present, although modified. Kernig especially notes this case as affording an instance where his sign was present, even in the absence of genuine inflammation.

On the other hand, Kernig's sign may be absent in meningitis (Netter, 13, Morse, 14). Morse found it in three of twenty cases of tuberculous meningitis, but in more than three of twenty cerebrospinal cases.

It will be noticed that this symptom was not present in the first and subsequent examinations up to a short time before death, and then it occurred only on the left side and to a limited extent. Microscopical sections did not show a meningitis in a strict sense of the term. There was only a tumor formation. This could, of course, have constituted the meningeal irritation in the broader sense of the term.

# ANÆSTHESIA BY NITROUS OXIDE, NITROUS OXIDE AND OXYGEN, NITROUS OXIDE AND ETHER, CHLOROFORM AND OXYGEN, AND ETHER ADMINISTERED PER RECTUM.

BY PRESCOTT LE BRETON, M. D.,  
Buffalo, N. Y.

During the past few years the writer has anesthetized over 300 private cases by the methods cited in the title of this paper for various operators. Nitrous oxide was given alone eighteen times, nitrous oxide and oxygen fifteen times, and ether by rectum six times. There was a large proportion of throat cases, 114 in all, the majority being given nitrous oxide and ether for the excision of tonsils and adenoids. In many of the cases the choice of the anæsthetic and its administration were of importance, on account of existing conditions—e. g., myocarditis, endocarditis, nephritis, diabetes, empyema, a preceding pneumonia, anemia, etc. There was one death from the anæsthetic in the series, of which the following is the history:

CASE I.—J. P. W., male, about forty-five years of age; operator, Dr. M. D. Mann; June 7, 1906.

A small irreducible hernia in the epigastric region was the condition necessitating operation. The patient had had since youth a rapid pulse, always over 100, and usually running 106 to 110. There was some increased tension. The heart sounds were apparently normal. The urine had showed some time previously albumin and casts, but nephritis at the time was absent. An asthmatic condition had existed for years, causing the patient to sleep at night in a chair until early morning, when it was possible for him to lie down. While asleep he showed Cheyne-Stokes breathing, there being in the interval a cessation of respiration for thirty seconds. Nitrous oxide and ether were chosen, and the patient was fortified by extra feeding, strychnine, and strophanthus the night, and the morning before operation. From the beginning of the anæsthesia the man did not relax well, but remained rigid and somewhat cyanotic. Eight minutes after the nitrous oxide was started and four minutes after the operation had begun, the heart suddenly stopped and deep cyanosis and dilatation of the pupils appeared. Artificial respiration, cardiac massage, and stimulants were of no avail. Ten gallons of nitrous oxide and three drachms of ether had been used.

I. *Nitrous Oxide*.—There is a class of cases in which a short period of narcosis is desirable, yet in which absolute relaxation is not required. For example, the reduction of a dislocation, excision of a small tumor, the breaking up of adhesions, etc. Nitrous oxide, continuously administered for ten to twenty minutes, controls such patients satisfactorily, and the after effects are slight. Women and children are the most favorable cases, whereas men and alcoholics are the least favorable. The administration is started in the usual way by the Goldan or Bennett apparatus until cyanosis begins to be evident; then the valve of the inhaler is closed by the finger and two breaths of pure air allowed. The valve is reopened and the inhalation immediately resumed, while a steady stream of nitrous oxide gas is allowed to escape into the rubber bag. Very shortly another breath of air is allowed, and the anæsthetic continued before the patient can recover consciousness. In about three minutes the typical picture is produced; slight constant cyanosis, contracted and not dilated pupils, snoring respiration with increased expiratory effort, and a pulse of eighty to ninety of increased tension. This condi-

tion is to be maintained by speedy regulation of the quantities of air and nitrous oxide gas inhaled. An increasing cyanosis, stertor, rigidity, and expiratory effort demand air inhalation, and the opposite condition calls for more nitrous oxide. A little experience teaches one how to appreciate the quick changes in the patient. A hypodermic of morphine, one half hour beforehand, although not essential, is of service. There are some cases that may show muscular rigidity or tremor, or they may cry out or move the extremities. One must be ready for this by having a bottle of ether at hand so that a drachm or more of this agent may be added. This changes the method to anæsthesia by nitrous oxide with a small quantity of ether.

2. *Nitrous Oxide and Oxygen for Prolonged Anæsthesia*.—The cut illustrates the apparatus, and for full details reference may be made to a former article on the subject (*New York Medical Journal*, February 13, 1904). This method is similar to the administration of gas. Instead of allowing frequent inhalations of air, an oxygen tank is connected by a T shaped tubing and a constant stream of oxygen is poured into the rubber bag along with the nitrous oxide. At first the oxygen is allowed in small quantities, but soon is increased in amount. The narcosis may often be continued for an hour or more and major operations may be performed. As with nitrous oxide alone, ether in small quantities may in some cases have to be added to insure smoothness. On account of the increased expiratory effort and the rather dark color of the blood, abdominal operations and procedures requiring fine dissection cannot well be performed. In operations on the head also, the anesthetist has too little room in which to work. This method is the most troublesome one and often an assistant is necessary to help manage the cylinders and keep the gas from freezing at the tap by wrapping about the valve and upper cylinder towels wet in hot water. If the apparatus is a closed inhaler—i. e., one that has no expiratory valve, it is essential that the patient be allowed at occasional intervals a breath or two of pure air. This method, on account of the expense, bulkiness of the apparatus, and difficulties of administration, has a limited use, and is employed in the larger cities only. A typical case is the following:

CASE II.—Boy, æt. twelve; removal of sarcoma of the knee by Dr. Gaylord. Time, forty-five minutes; no after effects. Soon afterwards an amputation at the thigh was done with the same method for anæsthesia plus one half ounce of ether. The second day after the operation there was a trace of albumin in the urine. Administration of chloroform, some weeks previously, had caused hæmaturia, which lasted three days.

3 (a). *Nitrous Oxide Given Continuously with the Addition of Small Quantities of Ether*.—In cases where a minimum of anæsthetic and a minimum of after effects are desirable, this method is of service. Small amounts of ether are added at intervals, and the disadvantages of the nitrous oxide alone are obviated. At any time nitrous oxide may be dispensed with and ether pushed for a short period by the drop method or cone, returning later to the nitrous oxide. About one quarter as much ether is given in this way as by the usual

means. It is particularly safe and the method that the writer prefers. The following is the history of a typical case:

CASE III.—Woman, æt. forty. Plastic operation on the perineum by Dr. Hendee. The son of this woman had died from the effects of chloroform administration. She herself had chronic nephritis with a high tension pulse. The urine was clear at the time of operation. The anæsthesia lasted two hours, and about sixty gallons of nitrous oxide and two ounces of ether were used. The second day after operation a trace of albumin was evident, but immediately disappeared.

3 (b). *Nitrous Oxide or Ethyl Chloride Used to Precede Straight Ether.*—This sequence is largely employed and is the method of choice in the large hospitals. It rapidly induces narcosis, saving time and material. The ether may then be given by the ordinary cone or the open drop method. Recent internes in the hospital are not successful as a rule, as they make the mistake of pushing nitrous oxide too far, and then beginning ether in full doses, which allows the patient to recover in part

Apparatus for the administration of nitrous oxide and oxygen for prolonged anæsthesia

and begin to struggle. The secret lies in overlapping broadly the administration of the two agents; a little ether should be run in on the gauze as soon as the patient begins to lose consciousness, and the nitrous oxide must be continued in small quantities until enough ether has been inhaled to hold the case while a change is made to the ordinary cone. It may take four to eight minutes to get an adult thoroughly under the influence of the anæsthetic, because during the first few minutes very little ether is inhaled.

For the removal of tonsils and adenoids this method is safe. Both agents are continued as described, the ether in increasing quantity, nitrous oxide in lessening amount, until the breathing is stertorous, the pupil contracted, and the eyeball fixed. The apparatus is removed, the mouth gag quickly inserted, and the operator begins his work. He ordinarily has time to finish before the patient moves. Sometimes a second dose of ether is required by the time the tonsils are excised, especial

ly if the punch has to be used. If the patient has a very irritable throat, coughs continuously, and refuses to breathe deeply, the nitrous oxide bag is discarded and ether is pushed by the cone. Anæsthesia is often troublesome in these throat cases because the existing conditions necessitate a deep narcosis before the throat reflexes disappear. For a few nose cases the writer has given nitrous oxide and ether satisfactorily in a semireclining position.

4. *Chloroform and Oxygen.*—For certain patients a minimum of chloroform only is indicated. A simple method is the following: Empty out the water in the bottle at the side of the oxygen tank and partly fill with chloroform. Replace the mouth-piece at the end of the rubber tubing by a small glass tubing. Pass this glass tubing through the upper end of an ether inhaler (the ordinary towel cone). Turn on the oxygen in a slow, steady stream and place the inhaler close to the patient's face, but not quite touching it. The patient at each inhalation breathes in the chloroform laden oxygen, and the quantity given is regulated by the speed of the oxygen stream and the proximity of the cone to the patient's face. The bottle holding the chloroform may be placed in a bowl of warm water, so that the vapor is warmed to blood heat as it is inhaled.

5. *Rectal Anæsthesia by Ether.*—The chief indication for this method is for cases in which extensive throat operations are to be done, so that the operator may work uninterruptedly. To Cunningham and Lahey (*Boston Medical and Surgical Journal*, April 20, 1905) belongs the credit for devising a new technique. The idea is simple. Air is forced by a hand bulb through an ether bottle and then through a rubber tubing into the rectum, which absorbs the ether vapor. No irritation is caused in this way, whereas by the old method of boiling the ether there was condensation in the rectum and great irritation. The writer has given ether in this way six times so far. In one case with perfect success, in one case with failure, and four times with practical success—i. e., in these four cases a few whiffs of chloroform on a gauze pad were essential at ten minute intervals to maintain relaxation. The rectum has a small absorbing surface when compared to the lungs, and in case the quantity of ether absorbed by the rectum is not quite enough to keep the patient quiet, then an additional agent is necessary. The writer at no time was able to drive the ether vapor beyond the rectum into the colon, because the sigmoid shuts off the ascent like a valve. Perhaps if the colon tube, used to give a high douche before operation, is left in situ until the operation, the vapor could then be absorbed in larger quantity by the colon. Any attempt to push the rectal tube up into the sigmoid caused the tube to double on itself.

The technique, in brief, is as follows: Two nights before the operation the patient takes a laxative. During the next day food is eaten sparingly, and the next evening a purgative is given. The following morning early a colon douche and an hour before operation a soap-suds enema are employed to cleanse colon and rectum. One half hour before operation a full hypodermatic injection of morphine is given. It is a convenience, but not a necessity, for

the anæsthetist to have an assistant. The apparatus consists of a rubber bulb, such as is attached to the Paquelin cautery, a wash bottle to hold the ether, rubber tubing about three feet long, a piece of glass tubing, and a large, stiff catheter or rectal tube. The wash bottle should be of a generous size, about seven inches high and four inches in diameter. It has a rubber cork perforated by two pieces of glass tubing, one of which descends to the bottom of the bottle. The bottle is more than half filled with ether and is placed in a wash bowl nearly full of warm water. The temperature of the water must not get over 90° F. or the ether will begin to boil, and yet it must be kept between 80° and 90° F. or else the ether vapor will not be concentrated. Starting the narcosis by the rectum is slow and distasteful to the patient, so the rule has been to have the rectal equipment close by on a small table in readiness, and the case is started by inhalation. A sand bag is placed under the thigh to afford working space, and the rectal tube is inserted about ten inches. The rectum is rapidly distended by compressing the hand bulb. The finger, protected by a rubber cot, is inserted for a few minutes into the rectum along the tube to empty the rectum of gas and provide for the absorption of ether vapor. Leggett, in a recent article (*Annals of Surgery*, October, 1907), suggests a Y shaped tubing fastened near the rectal tube, which, when opened on one side, affords escape for the gas in the rectum. Between the bottle and the rectal tube there is a piece of glass tubing, which is inspected at intervals to see that ether is not being forced over in a liquid form. The rectum is kept well distended by means of the hand bulb. The rectal tube needs watching, as it may slip out of the rectum. In general, from three to six ounces of ether are used in the course of an hour. When the operator has finished the rectum is emptied of gas as at the beginning. The patient recovers rapidly with little or no nausea and no proctitis. In fact, constipation is the rule, partly owing to the thorough cleansing of the alimentary tract before operation.

The chief advantage of this method lies in the fact that the operator can work steadily and finish in about half the time ordinarily consumed. A minor advantage is that there is no irritation of the respiratory tract with excess of mucus. The chief disadvantage is that if the ether absorbed by the rectum is not sufficient to hold the patient, the anæsthetic cannot push the administration any faster, but an assistant must give an extra supply by inhalation. The writer has used a little chloroform on a gauze pad, held by long forceps directly over the patient's mouth. This may have to be repeated at ten minute intervals.

In the hope of finding a medium better than air, whereby to hasten absorption, several experiments were made with nitrous oxide gas, allowing the rubber hand bulb to suck directly from a bag of gas instead of the open air. The idea was that the nitrogen of the air was disposed of very slowly, but that nitrous oxide loaded with ether vapor might be more rapidly taken up by the circulating blood. It was found that there was no practical difference in effect, although the ether was carried over in the

form of vapor just as fast by nitrous oxide as by the air.

CASE IV.—Baby, eight weeks old; preliminary operation by Dr. Eugene Smith for double hare lip and cleft palate, October 15, 1906. Castor oil, given the night before, had slight effect, and the colon wash was given too near the time of operation. Consequently, absorption was slow and fecal matter at times clogged the tube. Chloroform was necessary at intervals. Time, forty-five minutes, and one ounce of ether used.

CASE V.—The same baby, at a later date. Final operation by Dr. Smith. The preparation this time was thorough, and the child was completely anesthetized at first by inhalation. The operation lasted one hour, and three times during that period a few whiffs of chloroform had to be given. Dr. Smith was satisfied that he had worked faster and more comfortably than if inhalation had been continued throughout.

CASE VI.—Woman, æt. sixty-three years. Opening and draining of right antrum by Dr. Hinkel, October 17, 1906. Thorough preparation. Anæsthetization was started by ethyl chloride and ether. Time, thirty-five minutes, and two ounces of ether used. Complete success obtained, and the woman moved for the first time when the throat was swabbed out at the completion of the operation. Rapid recovery with no sequelæ.

CASE VII.—Girl, æt. twenty years. Opening and draining of frontal sinus by Dr. Hinkel, November 23, 1906. The preliminary inhalation was by ethyl chloride only, and she did not relax when the ether had been continued for some time. Finally chloroform had to be pushed vigorously and continuously before the third stage was reached. This patient, although slight, frail, and anæmic, belongs to that class occasionally seen who resist the influence of ether or chloroform until the anæsthetics are used most freely. She had been well prepared and had had the usual hypodermic morphine injection. Catheterization was necessary for some time following the operation.

CASE VIII.—Girl, æt. nine years, March 7, 1907. Removal of turbinate bones from each nostril and cleansing the ears of wax by Dr. Hinkel. Time, twenty-five minutes, and a few whiffs of chloroform given but once during that period. No after effects.

CASE IX.—Boy, æt. nine years, March 13, 1907. Removal of tonsils and adenoids and turbinates by Dr. Hinkel. Time, twenty-five minutes, and additional anæsthetic given once. Immediate recovery. These last two cases were well prepared and were both started by inhalation.

23 IRVING PLACE.

## SPONTANEOUS RUPTURE OF THE HEART.

*Report of a Case with Necropsy.*

By THEOPHIL KLINGMANN, M. D.,  
Ann Arbor, Mich.

This rare condition was first observed by Harvey, and later Morgagni wrote at length concerning it. Quain called attention to the fact that seventy-seven of the hundred cases collected by him showed marked fatty degeneration of the heart muscle. About two thirds of the patients were over sixty years of age.

Deverge asserts that in every forty cases of sudden death there is one by rupture of the heart. Sudden death occurred in 71 per cent. of Quain's cases. Out of fifty-five cases there were forty-three in which the rupture took place in the left ventricle, seven in the right ventricle, three in the right auricle, two in the left auricle.

The case which I am about to describe is quite not only from the fact that the condition is a very rare one, but also that it occurred in a subject of unusual good health, at the age of thirty-five years, without any previous symptoms.

**CASE.**—On October 23, 1906, the patient in question consulted me on account of a pain in the left cardiac region which he described as a deep boring pain which was paroxysmal. He complained of nothing else, and stated that he had been in perfect health since his childhood days. His father died suddenly at the age of seventy-nine of

FIG. 1.—Showing, a, the epicardial opening of the channel extending through the outer wall of the right ventricle; b, small opening entering into the descending branch of right coronary artery, which is closed by a thrombus higher up.

apoplexy, the mother was living at the time of the patient's death, but I have since learned that she fell over and died suddenly at the age of seventy-four. There was no autopsy, but the cause of death was ascribed to organic heart disease. The personal history of the patient is uneventful. He has never had any illness of any kind, except measles and whooping cough at an early age. His habits were good, and he denied venereal disease.

The patient was a rugged individual, weighing 180 pounds, five feet nine and a half inches in height, very muscular. The chest was broad and symmetrical, expansion equal on both sides, apex beat visible and strongly palpable in the fifth intercostal space, just inside of the nipple line. The superficial cardiac dullness was not increased, the heart's action was regular, there were no murmurs, the pulse seventy per minute and of good volume, tension about normal. There was a slight radial arteriosclerosis. The temporal arteries were somewhat tortuous. There was some tenderness of the sixth and seventh intercostal nerves on the left side; deep pressure on these nerves caused considerable pain radiating to the side of the chest and back. Aside from the conditions just mentioned the physical examination was negative. Analysis of the urine revealed nothing of importance.

I advised the patient to give up his work for a few days and rest, also directed him to apply counterirritation over the tender area, which he did, with the result that he was entirely relieved from the pain. In fact he told me that he felt perfectly well on the second day after he saw me, and undertook to do some light work about the farm.

On the morning of the third day he was suddenly taken

with an excruciating pain in the cardiac region where he had previously felt the pain. This was sharp and cutting in character and continuous. I saw him about half an hour after the onset of the paroxysm, and found him walking about the house in great agony. There was apparently no dyspnea, and he complained of no shortness of breath, no dizziness, nausea, or vomiting. On examination I found the pulse to be 55 a minute, of good volume, and not easily compressible. Respiration was 20. The apex beat was visible in the same place where I had located it three days before. The area of superficial cardiac dullness had increased considerably since I saw him, and repeated examination showed a continuous extension of this area. The apex beat gradually disappeared. I gave the patient  $\frac{1}{4}$  grain of morphine hypodermically, which I was obliged to repeat in three quarters of an hour, also applied an ice bag over the heart. The patient became quiet, but he stated that the pain continued. As time elapsed the pulse became slower, and was easily compressed. Respiration was shallow and gradually diminished, death taking place in one hour from the time of onset of the pain. The area of dullness in the cardiac region at the time of his death had extended one inch beyond the right sternal line, two inches to the left of the nipple line, upward to the lower border of the second rib and downward below the sixth rib.

**Autopsy.**—At the post mortem examination the pericardium was found enormously distended with a hæmorrhagic exudation in which there were a few small masses of clot. The myocardium of the left ventricle was firm, but of a pale waxy color; some parts of it were covered with a thick layer of fat. The outer wall of the right ventricle was less firm, in some places spongy; the appearance of the tissues were of a peculiar pale color, especially about the base of the papillary muscles; the tissue had a

FIG. 2.—Showing the epicardial opening of the channel extending through the outer wall of the right ventricle, and a small opening entering into the descending branch of the right coronary artery, which is closed by a thrombus higher up.

REMARKS.—The patient in question was a rugged, muscular, and healthy-looking man, who had been in perfect health since his childhood days. He was entirely relieved from the pain. In fact he told me that he felt perfectly well on the second day after he saw me, and undertook to do some light work about the farm.

rhagic infiltration. The condition of the myocardium was confined almost entirely to the outer wall of the right ventricle; there was an area 1.5 by 1.0 cm. situated near the base where the muscular tissue was substituted by a pale spongy tissue, in the centre of which was an opening horizontally oval, 8 mm. by 4, extending

FIG. 3.—Vertical transection through the tissues surrounding the rent in the outer wall of the right ventricle slightly magnified. a, Hole through the ventricular wall showing ragged margin. b, Broken down muscular tissue with infiltration of blood. c, Remaining heart muscle in various stages of degeneration. d, Portion of a bloodvessel showing thickened intima.

obliquely upward through the muscular wall into the right ventricular cavity, the inner opening being somewhat smaller and surrounded by a dark brown discoloration. The channel was empty, the tissues immediately surrounding the rent were discolored by considerable extravasation of blood. One and a half cm. to the right and 1 cm. below the opening just described there was another small opening entering into one of the branches of the right coronary artery and extending upward 1 cm. At this point there was a complete obstruction of the vessel by a thrombus. Below the opening the vessel was empty. The muscular tissue of the heart adjoining the rupture was undermined, very soft, shredded, and discolored, due to more or less infiltration of blood. The coronary arteries appeared diffusely opaque, and were hard and resistant; on slitting them open the walls were found to be much thickened, and the lumen very small in some parts of the

FIG. 4.—Showing fragmentation of the muscular tissue and infiltration of blood at the site of the rent through the ventricular wall.

larger branches. In others there were aneurysmal dilations with extremely thin walls. This was the condition where the obstruction was found, the portion of the vessel wall surrounding the thrombus was more than double the thickness on one side that it was on the other; while its wall

was extremely thin below the thrombus, where the rupture had taken place.

There were no marked changes in the endocardium aside from those described. In the aortic valves the tissue about the corpora arantii was somewhat thickened and the nodules enlarged. There was no marked infiltration in any of the valves and they retained their translucency.

**Microscopical Examination.**—The muscular fibres of the anterior wall of the right ventricle showed various degrees of degeneration; in the slightest changes they appeared somewhat swollen; diffusely stained, their nuclei did not take on stain readily or not at all, and in many places had disappeared. There were frequently large vacuoles and infiltration of fat throughout the sections. Surrounding the rupture there was every degree of change to total necrosis of the muscular fibres, which involved the entire thickness of the wall of the ventricle. In some areas there was an entire substitution of detritus and infiltration of blood, with an occasional fragment of heart muscle for the normal tissues of the heart. Although the condition of the myocardium was confined almost entirely to the right ventricle, there was considerable fatty infiltration throughout the muscular tissue of the heart and marked sclerosis of the coronary arteries.

Unfortunately the case is not a complete one, as a post mortem examination of the heart only was permitted.

In conclusion I may say that the rupture of the ventricle was a natural consequence following the endarteritis obliterans, the cause of which could not be determined.

## NOMA.

### A Bacteriological Study of Seven Cases.

By RANDLE C. ROSENBERG, M. D.,  
Philadelphia.

Assistant Professor of Bacteriology, Jefferson Medical College; and  
Director of the Clinical Laboratory of the Philadelphia Hospital.

The question of specificity of any certain organism bringing about the affection known as noma is apparently as far from settlement at the present day as it was some years ago. To some observers it seems certain to be due to one organism. A number of investigators have isolated different bacteria from the lesion, and each thought the bacterium specific, but others working along the same line of investigation have failed to prove these statements.

Numerous investigators have described a condition similar to noma in calves (Loßler and Lingard), in oxen (Bang), in monkeys (Lingard, Blackwood, and White), and in rabbits (Schmorl, *Zentralblatt für Bakteriologie*, xxi, 1890). As regards the pathology of the affection, most observers have noted the transition from ulcerative to gangrenous lesions, and Kraus (Nothnagel's *Specielle Pathologie und Therapie*) mentions that Taupin in 1839 stated that ulcerative and gangrenous stomatitis were essentially the same in nature.

Schimmellbusch's work in this connection is well known, as is also the assertion of Lingard that an organism isolated by him is specific for this affection. Perthes (*Archiv für klinische Chirurgie*, 1889) sets forth the assumption that noma is a mycosis which develops on the basis of some acquired predisposition, such as measles or typhoid, and caused by an organism which stands between the bacteria and threadlike parasites and should be grouped as a streptothrix. He has demonstrated in the diseased tissue the "streptothrix" of noma in

enormous threads, which in turn give off finer filaments, often dichotomously. The projecting filaments have a spirillum form, and the finest mycelia are found on the boundary line, and in the necrotic parts only thicker threads are seen and in small numbers.

Hermann (*Archives of Pediatrics*, November, 1905), in dealing with the aetiology of noma and after analyzing the article of Seiffert and Perthes (*Verhandlungen der medizinischen Gesellschaft zu Leipzig*, 1897 to 1901), alleges that the threadlike organisms found in the disease belong to the spirochaetae, which he asserts have such unusual characteristics that it would seem better to consider them a separate family.

Comba (*Jahrbuch für Kinderkrankheiten*, li, p. 591) believes that noma is always secondary to an ulcerative stomatitis, and that the process begins from without. The gangrene is due to the action of the saprophytes normally existing in the mouth, and becoming pathogenic under favorable conditions.

Jensen (*Handbuch der pathologischen Mikroorganismen*, II) found a bacillus which he named the *Bacillus necroseos*, and which has been found in necrotic processes in the horse, cow, pig, kangaroo, ape, stag, antelope, and rabbit. This organism, the *Bacillus necroseos*, Jensen asserts, is identical with Salomonsen's *Bacillus necroseos*, Löffler's *Bacillus diphtheriae vibulorum*, *Bacillus necrophorus* of Flüge, and the *Streptothrix cuniculi* of Schmorl.

Krahn (*Mittheilungen aus den Grenzgebieten der Medizin und Chirurgie*, VI) found comma bacilli at the boundary of necrotic and reactive tissue. He was unable to cultivate these comma shaped bacilli.

Weaver and Tunnicliffe (*Journal of Infectious Diseases*, January, 1907) summarize their findings in the necrotic tissue of the cheek in noma as follows: "There is some leucocytic invasion with fusiform bacilli and spirilla, similar to those seen in smear preparations made from the nose and mouth before death and from the necrotic tissue of the face immediately after death. Both forms are present in both the necrotic and living tissue, the spirilla forms apparently being in excess in both places. The thrombosed vessels contain fusiform bacilli, filaments, and spirilla. They believe these organisms are the threaded and spiral forms of one organism which correspond to forms shown by them to occur in pure cultures of fusiform bacilli."

Lingard (*Lancet*, April 14, 1888, p. 159) asserts that the essential character of the organism of noma is the same in human, monkey, calf, and horse. It consists of long threads, the individual threads being made up of small bacilli of various lengths, and are found at the line of extension of necrotic patches in great numbers. The inoculated disease is characterized by appearances precisely similar to those seen in the original malady.

Levi and Sailer (*Archives of Pediatrics*, 1905, p. 476) report a case of noma following typhoid fever in which a pure culture of the Klebs-Loeffler bacillus was found. Antitoxine did not give any benefit.

Moser (*Medical Record*, February 1, 1902, p. 170) records finding protozoa in three cases of

noma; they were small, oval bodies, little larger than a red blood cell, and were very lively in their movements.

Bruce (*Lancet*, October 12, 1907) mentions a case of Vincent's angina involving the larynx and trachea, occurring in a man, aged forty-seven. The patient made no complaint of his throat, but was suddenly seized with obstruction to respiration. Laryngotomy was performed, and examination of fauces showed sloughing of the uvula and the edge of the soft palate, and later extended to both sides of the neck. The bacillus of Vincent was present in large numbers, but no spirilla were observed. (It might be mentioned that a mild degree of pyorrhoea alveolaris was present, which might have been the

Illustration from a case of noma, which was bilateral from its inception.

starting point of the widespread gangrenous process.)

Blumer and MacFarlane (*American Journal of the Medical Sciences*, November, 1901), in an epidemic of measles, at the Albany Orphan Asylum, met with sixteen cases of noma. These cases affected the mouth, vulva, rectum, and other parts. In nine cases studied bacteriologically, the colon bacillus was found in all. Besides the colon bacillus was an organism that resembled a leptothrix. Pus cocci, and occasionally the *Streptococcus pyogenes*, were also present in some instances. These organisms were encountered in smears, and sections of one case studied bacteriologically showed the same bacteria.

Freymuth and Petruschky (*Deutsche medizinische Wochenschrift*, 1898, No. 15), in a case of noma genitalium, found true Klebbs-Loeffler bacilli, and while stating that all cases of noma are not due to this organism, it is well to make a careful bacteriological examination, as the bacillus produces necrosis and poisons and associates with putrefying bacteria.

Gravitz (*Deutsche medizinische Wochenschrift*, 1890, p. 318) reports a case of noma following typhus, in which a bacillus was the only organism present. (No specific description of this bacillus was given.)

Foote (*American Journal of the Medical Sciences*, cvii, p. 198, 1893) found few long bacilli in groups which stained by Gram's method in spreads made from the lesion while in the tissue, single bacilli often end to end and in filaments were encountered.

Bruning (*Jahrbuch für Kinderkrankheiten*, lx, p. 631, 1904) reports four cases of noma, in which, in two cases, a cladothrix was obtained in spreads and also in the tissue. Inoculation into animals did not produce any lesions whatever.

Walsh (*Proceedings of the Pathological Society of Philadelphia*, June, 1901) found true diphtheria bacilli in a case of noma, and likens the process to moist gangrene, where a saprophyte produces the putrefaction and a parasite produces the necrosis. He concludes that, whenever other pathogenic microbes capable of producing necrosis are found, it is possible that they may be the primary excitants.

Fischer (*American Journal of the Medical Sciences*, April, 1902) mentions a case of noma in which a nonpathogenic staphylococcus and a pleomorphic nonpathogenic bacillus which resembled the *Bacillus diphtheriae* were obtained. Hofman and Kusser (*Münchener medizinische Wochenschrift*, October 25, 1905) succeeded in isolating a bacillus 4 to 5 micra long and 0.8 micron in thickness, which in fluid media formed chains up to 40 micra in length. Spores were abundantly developed in forty-eight hours, and the organism grew well upon all ordinary culture media.

When noma follows some acute infectious disease, as typhoid fever, the specific organism of that disease may be isolated together with other bacteria. Such a case is reported by Ravenna (*Il Policlinico*, May and June, 1904), in which the *Bacillus typhosus* was isolated from the blood as well as from the gangrenous areas. A large number of observers have isolated bacteria which morphologically and tintorially resemble the diphtheria bacillus. Upon further study of these bacilli, some were virulent, while most of them were of the pseudo or nonvirulent type of the organism.

The seven cases collected by the writer include one following typhoid fever and six following measles. Spreads were made from all the patients during life and after death. The bacterial flora observed in all the cases was so similar that a general description will suffice. Foremost and most abundant was the spirillum and fusiform bacillus of Vincent; next in frequency were diphtheria like organisms, streptococci, staphylococci, and, in a couple of cases, pneumococci. As just mentioned, the fusi-

form bacillus and the spirillum of Vincent were the most abundant organisms present in the smears.

In four cases inoculations were made upon agar, blood serum, bouillon, egg medium (Dorsett). The tubes were incubated, and the resulting growth consisted principally of an organism resembling the *Bacillus diphtheriae*. It showed granular and beaded forms which were quite pronounced with Andrade's stain, was Gram positive, and in a few spreads some few organisms responded positively to Neisser's stain. Together with this bacillus was an organism that resembled the pneumococcus and a few streptococci.

The bacillus was isolated in pure culture and inoculated into the flank of a guinea pig. Three days afterward, an apparently painful swelling of the inoculated part was noticed. The animal did not move about with its accustomed vigor and was irritable when handled. On the fifth day the animal appeared to suffer considerably and got about the cage upon three legs. Loss of appetite supervened, emaciation set in, and the animal was killed. At this time the swollen area had broken down and an ulcer, or, more properly, a slough, 3.5 cm. in length and 2.5 cm. in breadth had formed. Spreads and inoculations were made from the slough and from the heart's blood. In the spreads the bacillus originally isolated was found, together with an organism resembling the pneumococcus. In the cultures from the slough the same two organisms were obtained. After obtaining a pure culture of the bacillus, 2 c.c. were inoculated into the peritoneal cavity of a guinea pig, but no toxic action was ever noticed.

The fifth case was interesting principally on account of the extent of the gangrenous slough and its bilateral aspect. The following short résumé is from the notes of the case given the writer by Dr. Frederick Johnson, then assistant chief resident at the Philadelphia Hospital:

The infection followed measles and was distinctly bilateral from its inception, never showed any demarcation tendencies; latent visible signs of gangrene; apparent freedom from pain; remarkable preservation of strength and ability to take nourishment until twelve hours prior to death; four thousand units of antitoxine of diphtheria given after first cauterization of the area, without any benefit; lungs remaining clear until the end.

At autopsy, inoculations were made upon different culture media and the same organisms were recovered as during life; the diphtheria like organism and in spreads the symbiotic organisms of Vincent.

The sixth case was one following typhoid fever; in spreads the same bacterial flora was observed, enumerated in the other cases. No organism resembling typhoid bacillus was ever demonstrable in spreads or in cultures.

The seventh case was one involving the groin. Spreads from this area of gangrene showed enormous numbers of micrococci and long, wavy filaments and spirilla like organisms. Anaerobic cultivations were made, and an organism resembling the *Bacillus necroseus* as well as micrococci were obtained.

In sections of tissue made from four cases, in two no organisms were seen except large emboli made up of micrococci. In the other two cases

enormous numbers of wavy and spiral, Gram negative, filaments were present together with micrococci and streptococci. Together with these was a small number of diphtheria like organisms. All these bacteria were best seen in the necrotic tissue, though a goodly number were seen penetrating into the healthy tissues.

These studies simply confirm the observations made by the majority of investigators, that no specific organism has as yet been isolated in this condition. I prefer to refer to the diphtheria like organism isolated by me as a pseudodiphtheria bacillus rather than to call it a true diphtheria bacillus. The reasons for this are that upon agar the growth was exceptionally abundant and the growth lacked the typical cream colored colonies as are so typical of the true diphtheria bacillus. It also was wanting in its toxic properties, as well as the subcultures upon various media. It is well known that the fusiform bacillus of Vincent is found in healthy mouths, and it is also a well known fact that the spirillum of Vincent is also seen in spreads from healthy persons. In the ulceromembranous stomatitis of Vincent both of these bacteria are present and generally in abundance.

It seems to the writer that the affection known as noma is due to a symbiosis of a number of bacteria, the principal ones of which are the symbiotic organisms of Vincent. The reasons advanced for this supposition are that the disease is first evidenced by a membranous or ulcerative process; that in this stage the fusiform bacillus and the spirillum of Vincent are present in great numbers; later, as the process goes on to gangrene, other organisms like the diphtheria like organism, streptococci, or other microorganisms, make their appearance, and from this latter invasion toxæmia develops, and the disease goes on to a fatal termination. These facts are borne out by the study of these cases and the bacteriological findings.

In conclusion, I wish to express my thanks to Dr. Frederick Johnson for the notes of the one case, together with the illustration of the bilateral lesion; to Dr. J. D. Wilson and Dr. John Funke for one case each.

2330 NORTH THIRTEENTH STREET.

#### NOTES ON EUROPEAN SURGICAL CLINICS.\*

By OLIVER C. SMITH, M. D.,  
Hartford, Conn.

To the average medical man there is no vacation more restful and beneficial than a trip to Europe. The enforced idleness, the fresh air, the cold salt baths, and good food on a transatlantic steamer furnish the ideal requirements for rest and recuperation.

Most medical men feel, however, that they cannot afford to take a long vacation without improving some of the time in a professional way. There is always so much to be learned that it is a natural temptation to endeavor to combine the requirements of professional knowledge with rest and pleasure. Some one has estimated that five thousand Ameri-

can physicians go abroad annually, and that during the past year the American people have spent \$500,000,000 in Europe.

It has occurred to the writer that the time has arrived when a guide book to the European clinics is an essential addition to the medical man's library. If Carl Baedeker could be induced to prepare a careful guide containing the names of hospitals, the attending physicians and surgeons, the hours for clinics and operations, and the opportunity at various places for courses in various branches, it would be a great aid to the American doctor who goes to Europe, especially for the first time.

The American must be prepared to find prominent European physicians and surgeons away on their vacation during the month of August and sometimes portions of July and September.

It is expedient, if one has a decided preference for some operator, to write before leaving America and learn his plans. It is unwise to travel far with the hope of finding the operator whom one wishes to see without previously obtaining information. It is true that at the large hospitals and clinics the work must go on, but it is usually conducted by assistants during the weeks before mentioned.

Letters of introduction are a decided aid. In the absence of these, a card bearing one's name and the positions, hospital appointments, etc., which one occupies is a decided help in receiving some degree of attention at the hands of foreign surgeons.

The route taken by the writer during the past summer was by Hamburg-American steamer, landing at Hamburg at the end of ten days' delightful voyage.

Hamburg is a pleasant city, and far from being a bad place to spend one's vacation. The *Allgemeines Krankenhaus* is a fine, large, modern hospital built on the pavilion plan and well conducted. Professor Kümmel and Professor Sich have charge of the surgical work; distinguished men in other lines are also in attendance. A large three story building is devoted to surgical operations, the amphitheatre being upon the second floor. The patients are wheeled from the various pavilions to the surgical building, thence upon an inclined plane to the operating rooms in comfortable, covered conveyances.

As a sample of the amount and character of work performed in one day, the following list of operations is quoted: Appendectomy; pelvic tuberculosis with removal of both ovaries and tubes; vaginal hysterectomy under spinal tropacocaine anesthesia; cystic goitre; subdiaphragmatic spondylitis abscess; resection of knee joint for tuberculosis, also under spinal anesthesia.

The work performed at this hospital, to my mind, fully justifies the favorable comments made by Dr. Nicholas Senn in an article which appeared in his interesting series on European travel, published in the *Journal of the American Medical Association*. One could spend a very profitable week or fortnight at this place, devoting half of the day to the surgical clinic and the wards of the hospital and the balance of the day to recreation.

Hamburg is the home of the great Unna, skin specialist. The writer visited his private hospital,

\*Read before the Surgical Section of the Hartford Medical Society, September 23, 1907.

which is more quaint and antique than attractive, but the surroundings are impressive when one realizes that much of the pathology of the skin was elucidated on this spot.

From Hamburg to Berlin is a comfortable car ride of three hours.

Berlin is one of the most rapidly growing, prosperous, and modern cities of all Europe. It has been the home of distinguished surgeons, physicians, and scientists for many years.

The chair of surgery at the general hospital, made vacant by the death of von Bergmann, is now occupied by Professor Bier, formerly of the University of Bonn, who is the author of the hyperæmia treatment which bears his name. The writer was fortunate in finding Professor Bier at his post, and both heard him deliver clinic lectures and witnessed his operations.

Professor Körter operates at the *Krankenhaus Urban* Mondays, Wednesdays, and Fridays. The new hospital, only recently built with money left by Professor Virchow, is some distance from the centre of Berlin, and was not visited by the writer, but it is highly spoken of as a modern, up to date institution, where good work can be seen.

Halle. En route from Berlin to Vienna, the interesting university town of Halle is first reached, and here Professor von Braman occupies the chair of clinical surgery, and is a man well worth meeting. He has a most attractive, kindly face, with large physique, and lectures fluently and well. It was the last day of the college term when the writer visited this clinic, and besides listening to a review of the work that had been gone over surgically during the term, he was treated to an exhibition of eighteen postoperative cases, which included a wide and interesting range of surgery. We were treated to an interesting lecture by Professor Schwartze, joint author of the *Schwartze-Stacke* operation upon the mastoid. After the lecture he performed his classical, radical, mastoid operation. During the college session one could well afford to devote time to this hospital and observe the work of Professor von Braman.

Leipzig was next visited; a fine old University city, the home of Professor Trendelenburg, whom many of us listened to at the Boston meeting of the American Medical Association. Professor Trendelenburg speaks English fluently, is pleased to receive American guests, and goes out of his way to show his interesting hospital, his ingenious methods of teaching, and his operative work. A large collection of x ray plates are used in the course of instruction and thrown upon a screen, the amphitheatre being suddenly darkened by automatic sliding shutters at the ceiling and windows. Specimens and photographs, as well as Röntgen ray plates, can be thrown upon the screen, and appear remarkably clear, lifelike, and distinct.

The writer had the pleasure of witnessing Professor Trendelenburg operate on a double hernia, a multiple suppurative arthritis of traumatic origin; also a tuberculous ankle, a congenital dislocation of hip by the open method in a case where the method of Lorenz had failed, and an excision of varicose veins of the lower limbs.

Professor Trendelenburg is a man of large parts. He is ingenious, bright, and tolerant of others' teaching, a kindly gentleman and an excellent surgeon.

Vienna, the Mecca for the postgraduate in medicine, is reached after a long ride from Leipsic. Many of you have spent a far longer time at the interesting Austrian capital than the writer.

Certainly there is no one hospital where so many branches of the profession are taught and practised with such abundance of material as at Vienna. The college was not in session, but the surgical clinics were busy, and the assistants were making the most of their opportunity.

The work at Professor von Eiselsberg's clinic was being performed by first and third assistants, Dr. Clairmont and Dr. Haberer. The former speaks English and gives excellent courses in surgical diagnosis.

Diagonally across the court is the clinic of Professor Hochenegg, made famous during the past century by the work of Franz Such, Theodor Billroth, and Carl Gussenbauer. Dr. Hans Lorenz performed a large number of operations daily, and gave place to Dr. Albrecht before the writer's departure. Dr. Lorenz is a remarkably quick and careful operator. Visitors are welcome to both of these clinics. A list of the operations can be obtained in the morning, and one can alternate between the two and witness the procedures in which he is most interested.

Thorough asepsis is undertaken, and fairly well executed. Rubber gloves are worn in septic cases and cotton gloves in the clean cases. The work in both clinics is accomplished by the surgeons and assistants and one male steward, no nurses being in attendance. Silk is almost the universal suture and ligature material. Continuous sutures are rarely used. Long incisions are practised, but an apparent lack of careful exploration in abdominal work after one lesion has been discovered is occasionally observed. The wounds are never washed after the operation, it being felt that the blood is a safe sealing agent, and by introducing water contamination may be invited from the surrounding parts. Anæsthesia is usually by chloroform. Local cocaine infiltration is practised rather more frequently than with us.

The following list of operations is a fair sample of what can be seen at one of these clinics in one forenoon: 1. Cystic goitre; 2. Gastroenterostomy for tumor of the greater curvature of the stomach; 3. Aneurysm of the femoral artery; 4. Radical amputation of breast, including cervical, supraclavicular, and axillary glands and the pectoral muscles, the large unclosed space being closed by skin flaps, Thiersch method, taken from the upper arm; 5. Gastrojejunostomy for cancer of the pylorus.

The gastroenterostomies were performed between the posterior wall of the stomach and the jejunum, a short distance from the attached portion, this being performed without clamps, stay sutures being introduced into the wall of stomach and jejunum to the gastroëcic omentum. The operation is quick and simple, but rather hemorrhagic, the field sometimes soiling from the unclamped viscera. The

anastomotic opening made is from one half to two thirds the size recommended by English and American surgeons.

It is unfortunate for the surgeon that the operative work comes at the same hour that the autopsies are being performed in the post mortem building. Both rooms are so interesting one can ill afford to lose either. Professor Weichselbaum's official course during the college year is from twelve to one p. m., five times weekly. From six to ten autopsies are performed each morning, it being the law in Austria that people who die in the hospital come to autopsy regardless of the station of the patient.

The autopsies are well conducted. All physicians are invited to attend. There is a printed programme telling when the post mortems of the respective wards are held. On the desk are the "death cards," which are numbered. A like number is attached to the great toe of the corresponding cadaver. The "death card" tells the ward, the name of the patient, time of admittance, time of death, time when post mortem will be held, the clinical diagnosis, and the name of the clinician. The minutest pathological changes are noted, and specimens kept for the gross pathology courses of the afternoon and for subsequent further elucidation in the laboratory of Professor Weichselbaum, which is on the same floor of the post mortem building.

The course in gross pathology, conducted four afternoons each week by Professor Ghon, is most valuable and interesting. Professor Ghon devotes his entire time and life to this work. He speaks rapid Viennese German, but the demonstration of specimens can almost be comprehended by one who does not understand the language.

As many of you know, there is an association for the American physicians at Vienna, which is most helpful to its members in aiding them to secure what they require in the best and most economical manner. The association holds biweekly meetings, and its members are on the alert to guide and aid the recent arrivals. The registry is kept at the "Café Klinik," across the way from the hospital. The round table in the centre of the room is reserved for American physicians, and one can gather the information he requires without going further afield.

At this great Allgemeines Krankenhaus can also be found Professor Schauter, who, with his assistants, conducts a large gynaecological clinic.

Professor Wertheim's clinic is at the Elizabeth Hospital, and is most highly commended.

Professor Sukerkandl is found at the beautiful, new Rothschild Hospital, but a short distance from the General Hospital. As at other clinics which are associated with the university, there is more activity during the college session. It is not always possible to secure the courses one wishes during the month of August. For this reason it is better for those wishing to attend lengthy courses to go at another time, either in the spring, the late fall, or during the winter, but by the surgeon or physician on his vacation enough and more than enough can be seen daily to repay him for every moment spent at this institution.

It is to be hoped if Carl Baedeker prepares a

guide for the medical man traveling in Europe he will add a word of caution and advice as to the conduct of the visitor at the European clinics.

It is embarrassing to hear a spectator ask foolish questions and interrupt the operator, or to see him crowd closely up to the field of operation without the prescribed gown and to conduct himself in general as if this was his first visit to a surgical clinic. It is rather surprising, considering the frequency of such occurrences, that operators are as courteous to visitors as they are.

The time passes altogether too quickly at Vienna. The balmy atmosphere, the open air gardens, and the delightful music fill in the time that is not occupied at the hospitals, and round out each day to completeness.

Switzerland is the ideal country for a summer vacation. The beautiful scenery, the high elevation, the clear air, the picturesque lakes, the fine roads for tramping and motoring are a combination not found elsewhere in Continental Europe, and the Swiss are doing excellent surgery.

*Berne.* The writer for a second time visited the Kocher clinic at Berne. The elder Kocher was not at home, but his son was most courteous and willingly exhibited the postoperative cases in the ward and performed several operations with caution and skill.

In a case of cholelithiasis, he performed Bernays's cholecystenditis operation, and remarked that both he and his father did it frequently, and were surprised that it was not more generally performed. As a proof of his sincerity he announced that four years ago this operation had been successfully performed upon him.

In patients where the gallbladder is not drained they are allowed to sit up on the fourth and return to their homes at the end of the tenth day, which is a decided economy of time, as compared with the lengthy course of ordinary gallbladder drainage.

The ambulatory treatment for fractures of the femur was demonstrated, the patients being allowed to get up within two or three days following the fracture, the limb encased in plaster, and a thick soled shoe upon the foot of the well side.

Dr. Kocher reiterated his remarks at the last meeting of the American Medical Association upon their thyroid surgery, and told us that more and more they appreciated the importance of operating upon exophthalmic goitre in two or more stages, ligating the vessels to limit thyroid secretion before removing any portion of the gland.

The adage that a prophet is not without honor save in his own land is exemplified by the fact that the colleagues of Professor Kocher do not employ his method in work upon goitre, and it is a matter of surprise to visitors at the clinics, other than Professor Kocher's, to find that his methods are not carried out.

*Geneva.* The General Hospital at Geneva is an excellent institution. Professor Gerard is one of the most attractive, scientific, and conscientious surgeons that it was our pleasure to meet. While there he was most enthusiastic and courteous in showing us every detail of the various departments of the hospital and defining his methods of treatment. He

is a strong advocate of postoperative out of door life. The patients are early rolled out into the garden and there allowed to convalesce.

Tuberculous lesions are treated by the sun's rays, the affected part being exposed until the skin is tanned to a dark brown. In no other hospital on the Continent did we find an operating room so conscientiously guarded from the incursion of germs. Absolutely no one—nurse, operator, assistant, or visitor—enters the room without gown, cap, and rubber shoes.

The professor believes this the only way of impressing the importance of such asepsis on the student.

One leaves Professor Gerard's company feeling that he could wisely and cheerfully select him for his own surgeon.

Geneva now boasts of a remarkably up to date gynaecological hospital. It is a model in every sense of the word, scientifically and hygienically, and has every modern device for the comfort, safety, and convenience of the patients. The furnishings, especially the operating theatres, have the latest and most improved equipments, and are worthy of careful study by one interested in such matters. We found nothing like it in our travels. It was interesting to know that these excellent aseptic furnishings and appliances were of Swiss make.

To one having the building of a hospital in view, a visit to this institution would be of great benefit.

*Lausanne* is the home of Professor Roux, generally acknowledged to be Kocher's most illustrious pupil. The writer was disappointed in not finding him at his work.

*Paris.* The usual route from Vienna is through Paris. If one wishes to visit the hospitals or clinics at this great centre, it is especially desirable to have a letter of introduction.

There is much excellent, scientific work done at Paris, but there is some that is not particularly profitable to witness.

Dr. Fore in gynaecology, Dr. Doven in general surgery and gynaecology, and Dr. Albarran and Dr. Guion in genitourinary work, are all men of great fame. As a rule, these men are not to be found at home in the vacation months, but in such a great centre there is always something of interest.

For instance, at the old l'Hôpital St.-Louis there is a most extensive and interesting museum containing a collection of wax specimens of cutaneous diseases and Péan's wonderful collection of wax specimens of surgical pathology. One can profitably spend an entire day at this museum.

At *London*, The London Hospital, Whitechapel, furnishes abundant opportunity for witnessing a wide range of surgical operations. There are a dozen operating theatres, mostly in charge of men of distinction in certain lines, where work progresses each day in the week except Sunday.

The writer had the privilege of witnessing the genitourinary work of Mr. Hurry Fenwick at this institution.

Much may be seen in the same line at St. Peter's, Covent Garden. It is here that Mr. Frayer performs many of his prostatectomies.

The highest type of brain surgery in Europe is probably performed, by Sir Victor Horsley at the

National Hospital for Epileptics and Paralyzed, Queen Square, W. C.

At the Children's Hospital, Great Ormond street, Dr. Lane has an active surgical clinic, and performs a large number of cleft palate operations.

Bland Sutton can be found at the Middlesex Hospital, Regent street, W.

Mr. Mayo Robson, well known to us all through his writings, operates mostly at private hospitals, and for that reason a letter of introduction is essential to see his work.

Mr. Hubert V. Paterson, who read a paper in the stomach symposium at the Atlantic City meeting this year, operates at the Temperance Hospital. He does careful, conscientious work, and is very courteous to visitors.

At St. Mary's Hospital, Professor Wright, the champion of opsonin index theory, may be found. From what I could learn of his work he is very much respected by the profession of London.

*Liverpool.* Probably the most prolific orthopaedic clinic in England is conducted by Professor Robert Jones Nelson at Liverpool. The writer did not attend this clinic, but learned from others who had that twenty or more operations could be seen each Wednesday.

*Leeds.* The visit of the writer to Leeds, a four hours' ride from London, to witness the work of Mr. Moynihan, was interesting. Mr. Moynihan operates at the General Infirmary, also at a private hospital close by. His reputation in biliary and gastric surgery is probably excelled by none in England. I think it is fair to speak of him as the Mayo of his country. He is a dextrous, cool, methodical, an extremely cautious, and quiet operator. The contrast between the quiet of Mr. Moynihan's operating room, where scarcely any one speaks, not even the chief, to that of some of the operating rooms on the Continent, is marked, and one is forced to admire the English habit of speaking softly and working calmly and quietly.

If asked what is most to be admired and copied in the work of the European surgeon, the writer would answer: Their patience in pursuing a long course of preparation, their accurate knowledge of anatomy, their familiarity with gross pathology, their willingness to serve long periods as assistants before occupying the responsible post of full surgeon, and their devotion to the life with but small compensation.

If asked what features of the work of the American surgeon could be most profitably emulated abroad, the writer would answer: A more profound respect for the sacredness of the tissues of the human body, more thorough explorations in the abdominal cavity when it is entered, an endeavor at times to work through smaller incisions, more prompt hemostasis on the part of the assistants, more discrimination in the selection of ligature material, and greater neatness of technique.

Each may learn from the other; in years past we have learned chiefly from them, but at present the European surgeons are holding us in higher esteem, and are observing our work with more marked attention and respect than ever before.

## MILK AND EDUCATION.\*

BY GEORGE W. GOLER, M. D.,  
Rochester, N. Y.

A woman was complaining on one occasion to Dr. Osler that Providence had seen fit to take her little child, when the doctor interrupted with the remark, "Providence had nothing to do with it; it was dirty milk."—John Mason Knox.

Early, very early in the morning, and again late in the afternoon in thousands of barns in every State in the Union thousands of milch cattle are milked every day in the year in order to supply the millions of people of this great country with milk. Of these millions of people ten millions are children under five years of age. In round numbers, down in New York nearly half a million; in Boston, 60,000; in Philadelphia, 140,000; in Chicago, 200,000 babies under five years of age, all dependent upon milk for food. Ten millions of babies and many millions of people, some of them sick, must have this milk produced daily from the bodies of all these thousands of animals.

From these statements one would be led to think that the education and training of those intrusted with the production, transportation, and distribution of milk would be made the subject of the State's greatest care. For are we not taught that the State depends upon the physical, mental, and moral welfare of its children for the perpetuation of the nation?

Do we see evidences of that care that milk demands by either the producer or the retailer? Does the producer handle his milk carefully, care for his utensils properly, store and transport it carefully, protect it at the railroad depots and provide for icing it on trains? Does the producer or the retailer clean his cans or utensils as they ought to be cleaned? Does he keep the milk cold, or does he substitute pasteurizing or preservatives for ice? Is there even provision for determining what percentage of the milch cattle are subject to tuberculosis? What man may enter the business of milk production? Has he training? Does he enter the business of dealer in the most perishable of foods with that education and training which these millions of infants have a right to demand for their protection, and which we, the State, should demand for them? They can neither speak nor vote as we men can vote or as both men and women can speak.

Inspection of milk and the protection which it should insure are both sadly lacking.

Is there a model farm where the dairyman may see and learn how he ought to produce and handle his product with financial advantage to himself and sanitary advantage to you? Is there a model dairy where the retailers of milk may learn how best to handle milk and how best to clean and keep clean milk and milk utensils? The men who work as butchers, the men who cut your corns or humors, the men who bury your dead must all pass examinations before they can receive licenses to do these things, but the men who produce or who sell milk to the millions of babies in the United States of America are, as a class, without education or training in the simplest rules of cleanliness and by a mere declaration and on payment at most of a dollar or two may

purvey food to your children. With this food millions of germs are frequently found in every teaspoonful. The germs of tuberculosis, typhoid fever, and diphtheria, the poisons of scarlet fever are but too often conveyed from the faraway farm or the family of the retailer to the children of the State.

When will we as a people awaken to the necessity for clean milk? Not so much because milk may cause the death of many infants, but because of the danger of disease in the years of the child's formative state, when the energies of the body should be used for growth, and not for resisting disease carried to it by milk.

In the countries of Europe the subject of milk as food for babies has received much attention within the last decade. Abroad they have begun to realize that the character of the milk supplied to the babies is of importance because milk is almost the sole food of the baby. They have found, as in Berlin, for instance, that in 1895 45 per cent. of their infants were breast fed, but that in 1905 the number of breast fed children had diminished to less than 33 per cent. We have in this country to-day, on the authorities of special workers in children's diseases, less than 25 per cent. of mothers in affluent circumstances who are able to nurse their children. Other evidence could be adduced to show that the number of naturally suckled children is diminishing, and this being the case, we are compelled to fall back upon the cow, to make our babies parasites upon a four footed board faced animal who may furnish excellent food for a calf, but only at the very best, indifferent food for a human baby.

Cows' milk, even chemically, is at best poor food for a human baby. It clots in larger and more indigestible lumps than woman's milk. It has a different fat, albumin, and sugar content than human milk. With all the skill of the most scientific treatment, it is both chemically and physiologically unfit for a human baby. Artificial treatment, predigestion, gruel mixtures, make it poor indeed in comparison with human milk. The only way to make cows' milk fit for a human baby is to feed it into the digestive tract of the human mother, in whose system it should be elaborated for her baby into human milk droplets from her breasts.

But we have before us the problem of 75 per cent. of our nurslings to be fed by the cow. We know the foul, dark, ill ventilated, dirty stables, the dirty cows and cans and utensils, the flies, the swarms of bacteria in the artificial food of the baby. We know of the poor makeshifts, the strainers, the temptation to condense, cook, and pasteurize, and otherwise "ize" this food, and all the time those of us who are striving to teach the value of clean milk are learning the lesson of depopulated France, Germany, and other European countries, viz., that the most precious thing in the world is the human baby. We are learning this lesson, not yet perhaps as they have learned it, because in Europe the mothers bear children, and, bearing children, attempt to rear them, but here our native American women no longer bear children as they once did, and so, as we import raw products of other kinds, we are now beginning to import most of our mothers.

But if we have not a large proportion of native born children, let us try to keep those we have and

\*Read before the New York State Sanitary Commission at Buffalo.

all other children alive and well. Let us try to realize that the baby is a future citizen. Let us try to look upon the protection of the milk supply as one of the greatest measures of protection for these citizens. Milk is secondary in importance only to water. All people may and should join in protecting this great food supply. The physician especially may do much to advance this work if he will acquaint his patients with the necessity of procuring clean, cold milk, unchanged by any Pasteurizing or so called concentrating process, and for protecting that milk by cleanliness and by icing, both before and after it reaches the consumer. The physician can assist in the establishment of milk stations throughout the city. Especially should such stations be established in connection with hospitals, particularly in those hospitals where clinics are held, so that the nurses in charge of the work and the physicians and students attending the clinics may observe the value of clean milk in the artificial feeding of infants. It is notorious that hospitals, as a rule, have the worst of milk supplies. It is supposed that their drugs are pure. Do they pay less attention to their milk than to their drugs? A patient becomes sick, the physician puts the patient upon a milk diet. How often does he know whence the milk comes, and whether it is clean or dirty? The importance of milk as food for older sick people is considerable, but of how much greater importance is it when the milk is to become food for infants! The results obtained from systematic milk inspection and through the work of milk stations are remarkable, but still more remarkable are the results shown in the figures taken during the last three months in Rochester, where all the deaths in infants under one year of age have been investigated with reference to whether the infants were breast fed or artificially fed, and if artificially fed, what was the standard of the milk obtained for their food.

During the months of July, August, and September, the months of heaviest infantile mortality, there were 144 deaths in infants under one year of age. Of these (excluding four less than forty-eight hours old) twenty-two were breast fed, 122 bottle fed, and of these 122 bottle fed children who died during those three months not one of them received a really safe milk supply.

It may be fairly assumed that the breast fed infants of the alleys have a far greater chance for life than their artificially fed brothers or sisters of the avenues. The children of those parents in affluent circumstances, when artificially fed, have a greater chance for life than the child so fed in the slums, or the carelessly fed child of a higher social grade. Artificially fed infants will thrive better on clean cows' milk in hot weather than on dirty milk in hot weather. They will even do better on home Pasteurized or sterilized dirty milk than when fed on untreated dirty milk, but they will also do far better if artificially fed on clean, uncooked milk than on the best kind of commercially Pasteurized or sterilized milk.

Figures for ten years show that infants do not die as frequently in cold weather on dirty milk as in hot weather. Else why do they not die in such great numbers in January as in July? The infant will stand dirty milk and cold, and it will endure heat alone, but it will not endure dirty milk and heat to-

gether. Clean, cold milk is the great necessity for the artificially fed baby. How many cities have clean milk—milk that can be trusted as a food for infants? Do you know of one city? How many cities have cold milk? Do you know of one? There are at least ten such cities. These are the cities that have a milk ordinance requiring milk to be delivered under 50° F. New York, Boston, Brockton, Los Angeles, Detroit, Cleveland, Cincinnati, St. Louis, St. Paul, and Minneapolis have such an ordinance. No city in New York State but New York City. Why? How many cities are feeding milk from tuberculous cattle, feeding it to their men and women with perhaps sufficient power to resist the disease, but feeding it as well to their infants who may grow up to become patients in the sanatoria for tuberculosis that are to be built for their reception in the future? The only cities buying milk from tuberculin tested cows are Grand Rapids, Mich.; Minneapolis and St. Paul, Minn.; Montclair, N. J.; Denver and Colorado Springs, Colo.; Brookline and Lynn, Mass.; Milwaukee, Wisc.; and Pasadena, Cal. Why?

It is not until such questions as these have been answered by the public and until the facts which the answers to such questions should call forth have been made known to the public that we shall improve the condition of the milk. The improvement of the milk supply depends not only upon the education of the public, but upon the education of the milk producer and the milk retailer. The milk producer should be a trained dairyman. The State should have before him as schools of reference to which he may refer a number of model farms.

All the operations of dairying should be carried on on these farms, and should include the best method of preparing the soil, planting, gathering, and housing crops, selection of cattle, the housing, storing, and transportation of milk. For the further advantage of the milk producer a system of book-keeping should be so simplified as to show the operations of such farms. If the State should establish such farms, it would be unnecessary to provide new houses and new buildings. It would be a great deal better to secure old, partly run down places with old buildings, and bring these into the highest state of efficiency so that the small milk producer could learn how to improve his own place without going to the expense of new buildings.

Even cities could well conduct model farms with new buildings in connection with the park system, where a day nursery might be conducted in the park, and where the cows might supply milk for such a nursery. For the benefit of every producer and retailer every health department should have a system of milk inspection so arranged that the premises of the producer and those of the retailer are subjected to regular, quarterly inspections and the result of those inspections entered upon a score card in triplicate so that each record of inspection might be furnished to the health office, the producer and the retailer. Upon the score card used for the retailer all of the data should be gathered necessary to make a ready reference relating to the retailer's premises, the score of the producer's premises, the bacterial count, and a rough diagram of the milk room so that in conversing with the retailer the inspecting or licensing officer might have all the information in his

hands at a time in condensed form on a single sheet.

For the further benefit of the retailer there should be in every health office a model milk room in actual operation, consisting of a steam boiler, sinks, with hot and cold water, and a sterilizing box where the retailer might see and learn how to adapt the simplest principles of cleanliness and of can and utensil sterilization to the public needs.

Then, with the introduction and operation of a licensing system, the enforcement of a milk ordinance by law that should provide imprisonment for a second offense, no man should be permitted to send milk into the city until the licensing authority had been satisfied with the premises of his producer, the health of his cows, and the cleanliness of all his appurtenances; that the cows had been subjected to a tuberculin test, and that the shipping facilities of the railway would insure the milk being kept cold. The retailer, too, should be compelled to show his ability to comply with the ordinances before being permitted to sell milk. These are the rules that must be lived up to if we are to protect the food of our children.

We live in a great country, the people of which approach the highest civilization the world has ever seen. Since the Civil War all the arts and sciences have attained the most wonderful development. Everything in this great country of ours is so new that if we pause and look out upon the achievements of our people it might almost seem as if we had been transplanted into a new world, where, fairylike, a new order of living had been made possible in part of the cycle of the life of man. New modes of communication at a distance, new modes of travel, the work of man manifolded by wonderful machines, new plants, the earth's products quadrupled; all these until men, women, and children have become mere machines.

While we are growing new grains, grasses, fruits, and vegetables, we are cultivating, weeding, and protecting them. What are we doing for our children? Are we cultivating them? Are we doing for them what the agriculturist does for grasses, fruits, and flowers? Are we even in their formative state giving them decent food?

The subject discussed here is part of a great social question. Upon the feeding and the training of our children we must depend for the stability and strength of the home and of the nation. The children of to-day are to be the parents of the future. To be strong, to be good parents, they must be well fed. What are you going to do for the protection of their most necessary food? Will you leave it as it is, practically unprotected, or will you insist upon the enactment of laws for its protection, and the enforcement of the laws after they are enacted?

127 EAST AVENUE.

#### TUBERCULOSIS AMONG MEDICAL STUDENTS AND ITS POSSIBLE PREVENTION

By UNO J. WILE, M. D.,  
New York

The prevalence of pulmonary tuberculosis among medical students and those engaged in the practice of medicine is a well known and long recognized

fact. The records of private sanatoria for the cure of tuberculosis show that a very considerable percentage of all patients are drawn from these walks of life. Setting aside that group of cases in which there is a previous history of tuberculosis, and that group in which there may be inherited predisposition, there remains a large number of cases in which the infection has been acquired during the course of study, and where perhaps it can be traced to direct carelessness or ignorance on the part of the student, or lack of protection incommensurate with the exposure to which all students of medicine are necessarily subjected. This last group of cases, therefore, would seem justly to be called preventable cases, and it is the purpose of this paper to point out briefly the probable sources of contagion in such cases and to suggest measures whereby such cases might be prevented.

During his medical course the student is exposed to tuberculous infection, as well, of course, to other infections, in three places, namely, the clinical laboratory, the post mortem room, and the ward. I have purposely left out the special dispensaries for tuberculosis, as here the danger seems to be well appreciated, and elaborate precautions against the spread of infection are usually observed. Likewise in the bacteriological laboratories the danger is probably minimal, for the student in bacteriology, in order to avoid ordinary contamination, must observe a technique which of itself does obviate any possibility of infection from the organisms studied, if that organism be the Koch bacillus.

Obviously the best time to warn the student against exposing himself uselessly to tuberculous infection is early in his course. Therefore, as soon as the entering classes in medicine are enrolled they should be gathered together, and some one of their teachers should address them, explaining the necessary and unnecessary dangers to which they may be exposed in their ensuing four years of work and thereafter. They should be strongly advised against overwork, underexercise, and overstimulation. Too often these are the causes which break down the normal resistance and render the student, perhaps late in his course, a fit subject for infection with the tubercle bacillus. Secondly, should be pointed out to the new student the widespread incidence of slight tuberculous infection among healthy people—in other words, the German view, "Jeder Mann hat am Ende ein wenig Tuberculose." To many this will undoubtedly serve as an added warning against risking an already infected, although latent, process to further infection. Thirdly, the proper hygiene of life, which, after all, is the best prophylaxis, should be strongly emphasized. Unfortunately in large cities, where clinical opportunities are good, proper hygienic surroundings for the student are not equally good. He should be urged, however, to spend at least one hour each day in the open air, to retire and to rise at regular hours, the morning to be well initiated by the cold tub or sponge. Using his mind constantly, the student should, above all things, have good food, and it is indeed poor economy to neglect, as many of the students do, the cheap boarding houses usually found in the proximity of the hospital or college. House infection is without doubt a factor in some of the cases

of tuberculosis developing among students, and the new student should carefully question his landlady as to his predecessor, and, in any event, before entering it as his own, he should insist upon having the room fumigated, or at least thoroughly scrubbed from top to bottom. One evening a week for the theatre, or any other preferred diversion, is an excellent rule for the student to follow throughout his medical course, and if he can be urged to take Sunday off besides, away from his books, it would be much better, and, I believe, a real gain in his working capacity. Having pointed out these things, the new student should be reminded that, despite all precautions and advice, a few cases of tuberculosis will undoubtedly occur in his class, but that these would probably occur in the same proportion in any walk of life, and should cause no special alarm.

To return to the places where the student will necessarily be exposed, we may first speak of the ward. The chances of contamination are here very obvious. One patient suffering from tuberculosis may, through his own ignorance, or the neglect of those who should know better, contaminate an entire ward with tubercle bacilli. To minimize this great danger all patients who cough, no matter from what cause, should be instructed to cover the mouth with a piece of gauze, thus lessening the chance of droplet infection. These pieces of gauze should be collected at least once a day and burned; furthermore, all patients should have as a sputum receptacle, not the china cup or mug most often used, but the regulation tin covered sputum cups, which are lined with pasteboard boxes. These should be covered with sawdust and burned each day, and the receptacle easily sterilized by boiling or by immersion in strong carbohc acid. Not infrequently the cups ordinarily used are thrown on the floor and the sputum spilled all over; the tin covered pasteboard boxes seldom are spilled, even when thrown on the floor, owing to the cover and the small opening in the pasteboard.

With regard to the laboratory, no sputum should be examined in large bulk. It is obviously a difficult task to find rice bodies or elastic tissue in two to four hundred c.c. of sputum. To spread this amount out on glass plates is to contaminate too large a surface to be afterward satisfactorily sterilized. The proper receptacle for sputum examination is the wooden screw box, which is painted inside with black enamel. Into this the patient should expectorate one or twice only. The black surface enables one easily to discern the desirable elements for examination, without transferring the infectious material to another surface, and the boxes should then be covered and soon afterward burned. In all his manipulations in the sputum room the student should avoid contaminating his hands, and all sputa should be removed before they can become dry. Besides this, no room for examination of sputum is complete unless plenty of soap and water and some disinfectant is at hand, and no examination can be complete unless the student makes use of these, whether he thinks he has contaminated his hands or not.

In the post mortem room, possibly more than anywhere else, is the student exposed to tuberculous infection. In order thoroughly to understand dis-

eased tissues, whether tuberculous or not, the student must feel them. Contact with tuberculous tissue, of course, spreads the infection to the examining fingers, but the danger from this is probably not great if the means are at hand for immediate and thorough cleansing of the hands. Unfortunately, however, in an autopsy room much used and usually not overclean, the student may further contaminate himself in endeavoring to rid his hands of infection. The faucets and sinks are probably infected, and even the door knobs may be, by those who are careless enough to leave the room before washing. The use of thin rubber gloves in the autopsy room, or in the examination of pathological tissue, is, I think, to be recommended. It may be argued by some that the tactile sense is lost or not so good, but we have the evidence of the surgeons against this view. Certainly no measure which may protect the student, even if its efficacy is a question of doubt, should be neglected until shown beyond this doubt that it is useless.

It is quite believable that if these briefly outlined precautions are followed and insisted upon in the medical school and hospital, a certain number, at least, of cases of tuberculosis acquired during the medical student's course may be prevented.

332 WEST EIGHTY-EIGHTH STREET.

## Our Readers' Discussions.

### A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXX.—How do you distinguish alcoholic stupor from other conditions resembling it? (Closed January 15, 1908.)

LXXI.—How do you treat gallstone colic? (Answers due not later than February 15, 1908.)

LXXII.—How do you treat fracture of the patella? (Answers not later than March 16, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXIX has been awarded to Dr. Maurice A. Walker, of Dillon, Montana, whose article appeared on page 164 of the preceding number.

### PRIZE QUESTION NO. LXIX.

THE TREATMENT OF POST PARTUM HÆMORRHAGE.

(Continued from page 169.)

Dr. William H. Randle, of Germantown, Philadelphia, writes:

Successful treatment of post partum hæmorrhage depends, first, on prophylactics; second, absolute certainty that the uterus is empty; third, stimulating the tired and relaxed uterus (inertia), causing contraction.

Immediately after the child is born, the fundus of

the uterus should be firmly grasped and held for half an hour, when it should be more firmly grasped and massaged, thereby expelling the placenta. If during this thirty minutes (time between the birth of the child and expulsion of afterbirth) excessive hæmorrhage begins, the placenta should be removed by Credé method, and massage continued. Hypodermatic injections of aseptic ergot and strychnine 1/20 gr. should be given separately.

Should flow continue, the treatment at this stage is the same, whether hæmorrhage began before placenta was removed or after. Patient should be placed across the bed, buttocks well over the edge. The left hand should press the uterus well down; the right hand, rubber gloved or thoroughly sterilized, be passed quickly into the uterus and every particle of secundines removed. The uterus should then be irrigated with normal saline solution at temperature of 115° F. A glass nozzle attached to a four quart fountain syringe should be carried well up to the fundus and irrigated slowly; at the same time the left hand should hold the body of the uterus tightly. If the uterus is well contracted, hæmorrhage stopped, and pulse good, the patient can be replaced in proper position.

If, however, there is doubt of the hæmostasia, and patient shows acute anæmia, and complains of feeling faint, with rapid, weak pulse, grasp posterior lip of uterus with double tenaculum forceps, draw uterus well down and to either side, and note particularly whether there are any cervical lacerations. Hæmorrhage may be due to laceration of uterine artery. If so, one or two sutures with chromic catgut, No. 1, is the best remedy.

Should exsanguination at this time have reached an alarming condition, it is best to pack the uterus, carrying packing (iodoform gauze, 5 per cent.) up to the fundus (not through the fundus, which can be easily done), and pack firmly. It is also well to pack the vagina. Ice cap should now be placed over lower part of the abdomen, pillows removed from under the head, and foot of bed elevated about two feet. Give brandy, half ounce in water, every hour until two or three doses are given. If indicated at this time, another hypodermatic injection of ergot, and another of strychnine sulphate, 1/30 gr., should be given; concentrated liquid diet in small quantities, frequently repeated, and normal saline solution (enterocolysis), eight ounces every four hours, and patient kept at perfect rest, complete the treatment.

Obstetrics being one of the most important branches of medicine, no physician should assume responsibility of a case without going to his patient thoroughly equipped for any emergency that may arise. The armamentarium being so necessary for successful treatment, so much depending on being ready and acting promptly, it is quite in order here to state what the physician should have with him.

His obstetrical satchel should contain a Tarnier forceps (or the make he likes best); a short forceps; half a dozen well curved needles; a needle holder; a fountain syringe, a glass nozzle for the same; a double tenaculum forceps; a uterine dressing forceps; a hypodermatic syringe in good order; tincture of veratrum viride; scissors; two or three hæmostats; a yard of moist iodoform gauze, 5 per cent.; six

yards of sterile gauze; twenty day chromicized catgut, no. 1; a linen bobbin; bichloride tablets; tincture of green soap; tincture of ergot; chloroform; a can of ether; a pair of rubber gloves; and a glass catheter. This outfit can be carried in a satchel six by fifteen inches.

*Dr. J. W. Summers, of Chicago, Ill., writes:*

Post partum hæmorrhage, the gravest of all obstetrical emergencies, is, if properly and intelligently managed, the most amenable to treatment. Since it is due to multiple causes, there can be no hard and fast plan of treatment.

In some cases the treatment should begin with the first visit to the patient. If there is evidence of anæmia, severe constitutional diseases, degenerations of important organs, or history of hæmophilia, and previous severe hæmorrhages, treatment should be instituted at once for the alleviation of the condition. For anæmia judicious diet with roborant tonics and well regulated exercise and habits will do good, not only to the blood and vascular system, but to the musculature of the entire body as well.

The various constitutional diseases, of course, will call for treatment directed to their alleviation. If a history of hæmophilia or previous hæmorrhages is given, treatment must be directed to improving the pathology of the blood, and at the time of delivery provision must be made for emergencies. Calcium lactate, calcium chloride, iron, and, in some cases, small doses of manganese, should be administered. To gelatin, as food, is sometimes attributed the power of increasing coagulability of the blood and better fibrin formation.

Prophylaxis during delivery is the next step in treatment. Care must be taken to prevent too rapid expulsion of the foetus, which should be extracted only as rapidly as the uterus will contract firmly. It is sometimes necessary to hold the child back to stimulate the vigorous uterine contractions.

After delivery of the child, the uterus must be encouraged to contraction by mild irritation of the fundus by massage through the abdominal wall, until it can be felt as a hard mass low in the abdomen. Do not hasten to deliver the placenta unless you feel sure contraction is taking place. Then expel the placenta by Credé's method, which is one of massage. This, if well done, will stimulate uterine contractions. After the placenta is expelled the uterus should still be firmly held and kneaded at frequent intervals for some time. If contraction has occurred towels may be tightly folded and forced under a tight binder in such a manner as to keep up continuous pressure on the uterus.

But occasionally, with the greatest care in delivery and previously, the hæmorrhage will occur, and in these cases the alert and self possessed physician is the one who will succeed. No time is to be lost. If the patient is conscious give her a good sized dose of fluidextract of ergot at once, but if she is under an anæsthetic some of the hypodermatic preparations of ergot should be given without delay. This can be done by the nurse or some member of the family while the physician is giving his attention to the local condition.

The first thing to be done in a post partum hemorrhage is to introduce the gloved or sterilized hand into the vagina and search for vaginal or cervical tears, and if the cause is not found there the hand should be introduced into the uterus and internal and external massage instituted by placing the other hand upon the abdominal wall.

The cavity of the uterus must be explored while this is being done, to see if there is still some placental tissue or membrane attached. These, if found, must be detached at once, and the walls of the uterus palpated to be sure there is no rupture or laceration. If a tear is found it must be rapidly repaired or grasped with clamps until preparation can be made for its repair, but if none are found and the hemorrhage is from the uterine sinuses, continue the combined internal and external massage and compression for a reasonable time.

Added to this procedure, a hot intrauterine douche, temperature  $110^{\circ}$  to  $115^{\circ}$ , should be given. It will sometimes be found that this only serves to wash the blood away and does not promote contraction. If such is the case no time should be lost, but proceed at once to pack the uterus with wet strips of sterile gauze, or cloth of any kind in case gauze is not at hand. Tear the cloth in strips and place it in very hot water to sterilize it, and introduce it into the uterus tightly. The vagina should be tightly packed also, in order to prevent expulsion of the gauze from the uterus, and then a perineal binder should be placed on tightly, to hold the gauze in the vagina. These measures are usually sufficient to stop the flow.

If adrenalin is at hand, swabbing the cavity of the uterus with 1 in 3,000 solution will often do good, since it is a powerful hemostatic when applied locally. Should no adrenalin be obtainable, acetic acid or sterile vinegar will do good.

Ice is an excellent stimulator of muscular contraction, and if the hemorrhage is so unexpected that no hot water or other measures are ready, a small piece of ice should be introduced and the cavity of the uterus massaged with it. This is excellent to promote contraction, but it causes some shock and even necrosis if allowed to remain too long, and, besides, ice is not always sterile. However, it may be used to good advantage in absence of other measures.

When hemorrhage is so severe as to cause fainting or unconsciousness, the foot of the bed should be elevated, and in very severe cases the limbs bandaged, hypodermoclysis or intravenous saline given, and heat applied. In less severe hemorrhages, high enemata of normal saline, plain or with a small amount of whiskey added for its stimulating effect. This acts quickly, and the simplicity of it often makes it more useful than hypodermoclysis or intravenous infusion.

Strychnine, camphorated oil, and other stimulants should be given if the condition of the patient requires them.

In hospital practice the control of post partum hemorrhage and the prevention of sepsis is a fairly easy feat, but in the poorly equipped home it assumes grave aspects and demands the best thought and self-control of the obstetrician.

*Dr. Iva M. Lickly, of Lima, Ohio, remarks:*

The most successful treatment of post partum hemorrhage lies in prophylaxis. An understanding of its etiology is therefore necessary.

As soon as the child is born a nurse or assistant should place her hand upon the mother's abdominal wall. If it is not unduly relaxed, the uterus will be felt as a firm, round body. If relaxed and bleeding occurs, the uterus should be massaged to secure contraction. The hand should then remain over the fundus until the placenta separates spontaneously, which will be indicated by a rising up of the fundus. If the patient is watched in this way, one will not be surprised by a concealed hemorrhage.

Usually the placenta will be expelled spontaneously. If not, Credé's method may be used after the placenta is separated, or if bleeding occurs. Impatience of the obstetrician and too early attempts at Credé's method often cause retention of portions of the placenta and consequent hemorrhage.

In rare cases the hemorrhage may be caused by adherent placenta. Then it may become necessary to insert the hand into the uterus to remove the placenta. Strict obedience to the rules of asepsis must then be observed, for danger of sepsis is great. The hand should follow the cord into the uterus and the edge of the placenta found. Then the placenta should be carefully peeled from the uterine wall. The hand then grasps the placenta, but should not be removed at once from the uterine cavity, but should be slowly withdrawn after the uterus contracts firmly over the hand. As soon as the placenta is expelled or contracted, it should be carefully examined for missing portions. If any part is absent, its removal will become necessary. This may be done according to method for removal of adherent placenta.

Bleeding, continuing after the expulsion of the placenta entire, may be due to uterine inertia or to deep cervical tears. Rarely it may be due to rupture of the uterus or to complete inversion. These latter, fortunately rare, require surgical treatment.

As soon as the placenta is expelled, the uterus should be massaged through the abdominal wall to secure contraction. If it shows a tendency toward relaxation, fluidextract of ergot 5i may be given by mouth, or, better, aseptic ergot min. xxx to min. lx. may be injected deeply into the muscles of the thigh. The uterus must be palpated often during the first hour after the placenta is expelled and massaged when necessary.

If the hemorrhage is due to deep cervical, vaginal, or perineal tears, the blood will be bright, the flow constant, and not stopped by the contraction of the uterus. In that case a careful examination should be made and the laceration repaired.

If massage fails to stop the bleeding, an intrauterine douche of hot, sterile, normal salt solution should be given. It should not continue for over two or three minutes, for, while the first effect of the hot water is to cause contraction of the blood-vessels, if continued too long it defeats its own purpose by causing relaxation.

If this fails it will be necessary to pack the uterus with sterile gauze, either plain or iodoform. A roll of sterilized gauze four or five inches wide should always be carried for this purpose. The patient

should be brought to the edge of the bed, prepared as for an operation, and a Sims or bivalve speculum inserted. The cervix should be brought down with a tenaculum and the uterus and upper vagina firmly packed. This packing should be removed in twenty-four hours by pulling on the free end.

The use of ice, vinegar, Monsel's solution, and other astringents may be mentioned only to be condemned. Ice and vinegar are never aseptic. Any astringent to be effective acts by forming a coagulum over the surface. This latter separates by sloughing. None of these methods are as effective as the intrauterine douche or packing the uterus. Following the latter methods one does not fear puerperal sepsis.

The after treatment is the treatment of shock. In mild cases, absolute quiet, elevation of the foot of the bed, and hot water bottles to the extremities will be sufficient. If, however, symptoms of profound shock occur, if the pulse is weak, of low pressure, and thready, and if the patient is restless and shows signs of "air hunger," more vigorous measures must be adopted. Strychnine nitrate, gr. 1/30, hypodermatically, repeated until three doses are given, is good treatment. Adrenalin extract is evanescent in its effects, but may tide the patient over a critical time until other things have time to act. It may be given hypodermatically, the dosage depending upon the preparation used. Brandy and ether may also be given hypodermatically.

Six ounces of hot coffee and salt solution (temperature 110° F.) may be given per rectum, or hot normal salt solution may be injected slowly high into the colon. It will be rapidly absorbed and prove a valuable aid.

In many cases of pronounced shock from hæmorrhage life has been saved by subcutaneous or intravenous injections of hot normal salt solution. If given by hypodermoclysis, the injection may be given under each breast, using at least a pint of solution and repeating as soon as absorption has occurred. If the case is very urgent, the solution should be given intravenously.

To sum up:

1. Hæmorrhage may usually be avoided by proper treatment.

2. If it occurs, (a) remove placenta; (b) massage uterus; (c) give ergot hypodermatically; (d) repair lacerations; (e) use hot sterile intrauterine douches, and (f) pack uterus.

3. After care: Heat stimulants. Hot normal salt by enteroclysis, hypodermoclysis, and intravenously.

*Dr. J. Lytle Moore, of Toledo, O., observes:*

After the expulsion of the placenta, normally there is a loss of a variable amount of blood. In cases where the uterus does not contract promptly or sufficiently this hæmorrhage may be so severe that the patient would be exsanguinated in a short time unless very prompt measures are taken to stop it.

The causes of post partum hæmorrhage may be briefly stated as: 1. Relaxation or insufficient contraction of the uterus. 2. Exertion, which causes a loosening of the clots in the uterine vessels. 3. Ruptured uterus. 4. Inverted uterus. 5. Lacerations

in the birth canal. 6. Tumors and new growths.

1. Relaxation of the uterine muscle is by far the most frequent cause of post partum hæmorrhage. The causative factors of relaxed uterus are those which interfere with the complete contraction of the organ, as retained placenta or clots, weakness of the uterine muscle from overstretching (twins, hydramnios, large child, etc.), or debility from general disease, adhesions around the uterus, distended bladder or rectum, fatigue from a protracted labor, rapid delivery, short time between pregnancies, etc.

The treatment of this form of post partum hæmorrhage divides itself into prophylactic, active, and after treatment.

Prophylaxis.—If there is systemic weakness or debility from any cause, this should be treated with tonics, good food, proper hygiene, etc., to get the patient in the best condition possible before delivery. At the onset of labor the rectum and bladder should be emptied. The physician should not allow the patient to become too much exhausted by a long labor. As soon as the head is born, a hypodermatic injection of ergot should be given and the fundus massaged to insure contraction. A firm abdominal binder should be applied to insure slight pressure.

Active Treatment.—Before giving my favorite procedure, I would like to mention a number of methods which are in use by the best physicians for stopping the bleeding.

a. External stimulation of the uterus. The best way is to massage the uterus through the abdominal walls. The fundus is grasped in the hand and kneaded and irritated. The uterus can also be stimulated to contract by the application of cold to the abdomen. A little ether can be poured upon the abdomen, or ice, or a cold compress can be used.

b. Internal stimulation. A comparatively safe and efficient method is the hot uterine douche. Water at a temperature of 120° F. should be used.

Pieces of ice are sometimes placed in the uterus. The chief objection to this is the danger of infection. Irritating drugs, as tincture of iodine, Monsel's solution, vinegar, etc., promptly cause uterine contraction when introduced into the organ. But they, too, have an objectionable side. They cause large clots to form in the vessels, and these are likely to form an embolism. I do not think them as safe as other methods.

Another method of internal stimulation is to introduce the left hand into the uterus, and massage it between the two hands until it is felt to contract down upon the inside hand. With proper attention to antisepsis the danger of infection is slight.

Tamponing the uterus.—Sterile gauze is packed into the uterus and vagina. This will usually stop all hæmorrhage. The gauze is left in from twenty-four to thirty-six hours. If hæmorrhage commences again after its removal, it should be repacked.

Compression of the uterus.—The fingers of the left hand are in the posterior cul-de-sac, and the right hand is over the pubes. The uterus is compressed between the two hands.

Pressure on the abdominal aorta is sometimes resorted to when all other methods fail. Authorities differ as to the value of this procedure.

In addition, ergot should always be given, and the child placed to the breasts when possible.

The following is the outline of the way I would treat a case of hæmorrhage arising from relaxed uterus: Place patient on her back, with head lowered; then give a hypodermic of ergot. Remove placenta if attached, correct inversions and misplacements if present. By external massage of the uterus hæmorrhage is usually controlled. If not, internal massage. Finally, if this does not control the bleeding, I resort to tamponing the uterus and vagina.

After treatment of all forms of post partum hæmorrhage is the same as hæmorrhage from any cause. In the less severe cases, give the patient a cup of strong, black coffee or some other stimulant, and keep up the body temperature by hot water bottles to the extremities. In severe cases, raise the foot of the bed, stimulate with a hypodermatic injection of ether, give an enema of hot saline solution, or a hypodermoclysis. After reaction, quiet the patient with morphine, and give stimulants, digitalis, strychnine, etc. Keep the patient perfectly quiet, and allow only a liquid diet. Later put her on tonic treatment.

2. High arterial tension, or exertion on the part of the patient may cause loosening of the clots. This should receive appropriate treatment, viz., quietness or drugs to lower arterial tension.

3. Inverted uterus.—If the placenta is adherent, remove it and then replace the uterus. If it does not contract, the methods given before should be tried, or it should be packed with gauze.

4. Lacerations of birth canal.—If possible, pick up and tie the bleeding vessels and repair the tears. If this cannot be done, pack the uterus or vagina, whichever is necessary. Later, this is to be removed and the rents sewed up.

Hæmorrhages from other causes are more rare, and their treatment is that of the causative factors.

*Dr. Parker F. Southwick, of Sandusky, Ohio, states:*

As relaxation and loss of contractile power of the uterine muscle is the most frequent cause of post partum hæmorrhage, any treatment to be effective must be directed to these conditions, the object being to secure firm and prolonged contraction of the womb. To this end especial care should be exerted in the third stage of labor.

After birth of the child some little time should elapse before any attempt is made to deliver the placenta, thus allowing the fatigued and overworked uterus time to regain its lost muscular tone. The placenta having been removed by the expression method, the hand should maintain this external pressure, and at the same time make gentle kneading movements over the womb. If the uterus is not firmly contracted and there is some hæmorrhage, 5i or ʒi of extract of ergot should be given by mouth. Then give a hot vaginal douche of sterile water at a temperature of 112° F. If it produces no effect give an intrauterine douche consisting of sterile water, normal salt solution, or a 2 per cent. solution of acetic acid; if the latter is not at hand, vinegar may be used. The use of the hot douche is extremely valuable, but is not always possible to give without trained assistants. During these procedures the

mechanical stimulation through the abdominal walls should be maintained. If hæmorrhage continues, repeat the ergot and introduce the free hand into the vagina, carry it up posteriorly to the cervix, and with both external and internal hands press the uterus firmly up under the symphysis pubes, always continuing the kneading movements of the external hand. If this produces no effect carry the hand up into the uterine cavity, removing all blood clots and placental remains. At the same time move the hand about rather roughly to incite a mechanical stimulation of the muscle, or close the hand in the uterus and make firm pressure over it with the external hand. Gauze soaked in vinegar and carried into the uterine cavity may bring about desired results.

Should all these means fail to incite firm contraction and check the hæmorrhage, the uterine cavity is to be packed with sterile gauze. With the patient across the bed the gauze is carried to the fundus and firmly packed in from above downward, causing an immediate cessation of the hæmorrhage. Electricity and local styptics might be tried, but they are usually not at hand when most needed. Then, too, styptics are dangerous from the firm clots they produce in the uterine sinuses.

All of these measures in and about the parturient canal should be carried out under strict aseptic precautions, as the uterus is especially liable to infection at this time.

In cases of mild hæmorrhage not controlled by mechanical irritation and the hot douches, careful inspection of the vagina and uterus should be made through a speculum. Often a tear in the vaginal or cervical tissue may be responsible for the bleeding. If found, immediate repair insures the desired result.

The cessation of the hæmorrhage is not the only consideration in these cases, as they are usually followed by depression, syncope, and acute anæmia, which demand immediate treatment.

The patient is to be kept perfectly quiet, with the foot of the bed raised six or eight inches, and heart stimulants, strychnine, digitalis, and brandy, administered as required. An enema consisting of

B	Adrenalin chloride, .....	ʒj;
	Brandy, .....	ʒi;
	Normal salt solution, .....	ʒviij.

M.

acts as a powerful stimulant, besides restoring the balance of fluids in the system. Normal salt solution may be given subcutaneously in immediate danger.

*Dr. C. C. Coryell, of New York, says:*

The treatment of post partum hæmorrhage divides itself into two divisions—the first prophylactic, the second curative.

1. *Prophylaxis.*—Since the causes of post partum hæmorrhage are not invariably similar, the preventive treatment is most important, and should include a proper regulation of diet and hygiene, especially during the latter weeks of gestation; the condition of overdistention of the uterus, due either to excessive hydramnios or multiple foetation should receive attention; also pregnancy should be terminated prematurely if the patient is markedly weakened by any systemic disease.

During labor itself care should be taken, first, to prevent a too rapid delivery, thereby causing insufficient uterine contraction or lacerations of the birth canal, and, secondly, to prevent a too prolonged labor, on account of which the uterine muscles fail to contract properly.

Beginning with the end of the second stage of labor the fundus should be held firmly through the abdominal wall and pressure continued thereafter until there are firm contractions after the termination of the third stage. However, if the placenta is not expelled after thirty minutes, the familiar method of Cr  d   should be employed, this being an important adjuvant as a preventive of post partum h  morrhage.

Immediately following the birth of the placenta fluidextract of ergot should be given by mouth (or a smaller dose subcutaneously) to promote uterine contractions; the placenta should be carefully inspected for possible retained membrane or cotyledons, and, if there is a probability of such being the case, the fingers (under aseptic precautions) should be passed into the uterus and shreds or clots removed.

**II. Curative.**—When, in spite of all preventive measures, there occurs a frank h  morrhage after the third stage of labor, the following methods of control should be employed.

Put the infant to breast of mother to promote reflex contractions of the uterus; rub and squeeze the fundus through the abdominal wall to produce direct contractions; pass the fingers into the cervix and remove clots of blood or retained portions of placenta or membranes. These procedures failing, pass the fingers of the right hand into the posterior vaginal fornix, pressing forward the cervix, while with the left hand seize the fundus through the abdominal wall and press downward and backward in an effort to bend the uterus upon itself; as a final method the closed fist of one hand should be placed inside the uterine cavity, and with the external hand squeeze the fundus upon it.

These manipulations, begun early and carried out rapidly, are invariably sufficient. Then a hot intra-uterine douche of sterile saline solution should be given. If there is a tendency for continued uterine relaxation, the fundus may be packed tightly with strips of sterile gauze, to be removed in twenty-four hours. Injections of substances such as vinegar, iron chloride, etc., are mentioned to be condemned. All manipulations are to be carried out under aseptic precautions if possible.

Following the control of the h  morrhage, the general treatment of the patient must be begun. Elevate the foot of the bed; give a hot saline enema, and, if considerable blood has been lost, a saline venous infusion or hypodermoclysis may be employed; stimulate with hypodermics of brandy, strychnine, or Hoffmann's anodyne, as indicated; place hot water bottles to extremities; morphia sulphate, gr. 1/4, hypodermatically is a valuable stimulant in cases of collapse.

After the patient has passed two or three days without h  morrhage, she may be considered out of danger. Then general tonic and dietetic treatment must be begun.

*Dr. Adolph Morgenstern, of New York, writes:*

The treatment applicable to a case of post partum h  morrhage is classed as (a) preventive and (b) curative.

I shall not consider remote prophylaxis, which deals with the preparation and treatment of a patient whose general condition, surroundings, or family history would warrant suspicions of a possible post partum h  morrhage. But I must devote a little space to the immediate or direct prophylaxis, i. e., the one pertaining to the proper management of the second and third stages of labor. I firmly believe that the least break in the technique of managing these two stages enhances some chance of a post partum h  morrhage. This is especially true in multipare, and particularly so where the patient is exhausted from tardy labor and somewhat prolonged chloroform narcosis. To be more explicit, I must of necessity give a brief review of the rearrangement of the uterine fibres after labor as well as the methods of aiding this process where the physiological return to the normal is somewhat retarded.

After the birth of the child, the hypertrophied uterine fibres, stretched during the period of gestation, begin to rearrange themselves, or, in other words, to tonically contract and relax. The mere touch of the fingers promotes and stimulates this tonic action of the uterus. Moreover, as the periods of contraction lengthen, the periods of relaxation shorten, and in about twenty to twenty-five minutes the uterus is usually firm enough to render the Cr  d   method possible. By virtue of these muscular contractions, which continue after the delivery of the placenta, the ligation of the uterine vessels is accomplished. Should the uterus present a boggy touch, Cr  d  's movements are to be instituted, and as one or more blood clots are expelled, the uterus regains its firmness. The hand should, under no circumstances, leave the fundus for at least one hour. The patient remains perfectly quiet, with thighs together and flat on the bed. A tight abdominal binder coming up to three inches above the fundus and reaching about two inches below the trochanters, is very effectual, for the reason that it supports the abdominal muscles, which in turn exert a certain amount of pressure on the uterus.

Slight h  morrhages usually originate from a badly lacerated cervix, vagina, or perin  um. These are best controlled by suture. The curative treatment of a post partum h  morrhage proper—that is, one having its origin at the placental site—I will discuss more fully. In the treatment of this last condition various manipulations are employed. In my experience the ordinary Cr  d   manoeuvre—that is, grasping the fundus between the hand and the thumb, and pressing the latter against the dorsum, simultaneously directing considerable force downward—has been most satisfactory. Breisky's method is also very efficacious. I have controlled some moderate h  morrhages by holding the right hand at a point corresponding to the junction of the body and cervix, and forcibly anteflexing the uterus with the left. In these external manipulations a certain amount of pressure is also exerted on the abdominal aorta. The combined internal and ex-

ternal manipulation does not appeal to me, because of the possible dangers of embolism and infection consequent upon such a procedure.

To my mind the hot douche of sterile water at a temperature of  $116^{\circ}$  to  $120^{\circ}$  F. is only applicable in hospital practice. In the tenement houses of this city it is exceedingly difficult to obtain sterile water, and much more so at an optimum temperature. The styptic effect alleged from a hot 1 per cent. to 5 per cent. acetic acid douche is too slight to be of any value, consequently hardly worth while trying.

Uterine tamponade is the most efficient method for the control of severe hæmorrhages following hæmophilia or marked atony of the uterus in consequence of inertia uteri from exhaustion, overdistension of the uterus from any cause, and where simpler methods have failed. The method I employ is extremely simple. Strip iodoform gauze one and one half or two inches wide is carried with a uterine dressing forceps, or, in emergency, with the fingers, clear up to the fundus, until the whole uterine cavity is filled with gauze. The fundus is then grasped with the left hand, while the middle finger of the right, introduced into the cervix, squeezes the gauze against the fundus to insure tight packing of the uterus. The cervix, fornices, and upper vagina are then tightly packed. This, I find, can be done more thoroughly with the fingers than with instruments.

The gauze should carefully be removed after twelve hours. It is permissible, however, to leave it in the uterus for twenty-four hours, and, in very rare instances, for forty-eight hours without the least untoward effects.

Most standard authors invariably recommend unmedicated sterile gauze for intrauterine tamponade, but I fail to see its advantages over iodoform gauze. On the contrary, to my mind, 5 per cent. iodoform gauze is the safer of the two from the standpoint of asepsis. Out of about seventy-five cases packed with iodoform gauze, I only recall one patient whose urine gave the iodoform test after the gauze was left in the uterine cavity for seventy-two hours. The other symptoms of iodoform were so slight that they entirely disappeared within twenty-four hours after removal of the cause. It stands to reason that in emergency, lacking iodoform gauze, plain gauze, bandages, or even strips of linen must be resorted to.

Various textbooks recommend additional measures for the control of post partum hæmorrhages, such as the application of the child to the breast as a reflex excitomotor, electricity in the shape of a faradic current, and swabbing the uterus with tincture of iodine. In my opinion, they are absolutely useless, for the reason that, considering the nature of the case, it is imperative to act and not theorize. All trifling methods must, of necessity, be discarded and the most efficient ones adopted. The only effective measures available can be summarized under the following tripod: 1. Ergot. 2. Manipulation. 3. Tampon.

The shock and anæmia should receive attention in proportion to the severity of symptoms. On general principles all pillows should be withdrawn from under the head, and the foot of the bed elevated. Hot water bags to the body, and drachm doses of

hot water, with or without brandy, given every few minutes; tend to keep the patient warm. Rectal enemata of equal parts of hot decinormal salt solution and strong black coffee, with one ounce of brandy or whiskey, are useful for the same reason. These measures not only stimulate the patient, but also replace the loss of blood to certain degree. Hypodermatic injections of strychnine, gr. 1/60, or digitalin, gr. 1/100, given p. r. n., are of value. In very severe cases autotransfusion by means of Esmarch or muslin bandages, hypodermoclysis, and intravenous infusions should be resorted to. The patient must be kept at absolute rest. For the first twenty-four hours a milk diet, later broths and predigested food should be given. On the third day semisolid food may be substituted, followed later by an easily digested general diet. A nutritive diet, with general tonics, will enable the patient to sit up in bed on about the fourteenth day post partum. Fresh air is an important adjuvant in the treatment of the anæmia. In my opinion, the organic compounds of iron are by far more satisfactory as blood producing agents than the inorganic combinations.

(To be concluded.)

## Therapeutical Notes.

### The Antiseptic Value of Iodic Acid and Iodates.

—Calcium iodate employed as a dusting powder, or as a 4 per cent. ointment with petrolatum, is said to be an excellent antiseptic for stubborn sores (*Journal pharmaceutique de Liège*). It may also be used as a warm saturated solution in the form of an injection for vaginal and vesical irrigation, and also as a wash for infantile eczema. It is considered an economical substitute for iodoform. An aqueous solution of iodic acid, 1 in 500, is an active deodorant of purulent wounds. Since calcium iodate is not very soluble, where strong solutions are required zinc iodate may be used; bismuth subiodate is useful as a dusting powder for tuberculous sores.

**Gelatin Solution for Hypodermatic Injection in Hæmorrhagic Conditions.**—A saline solution of gelatin for hypodermatic injection in hæmorrhagic conditions is made, according to the *Pharmaceutisch Weekblad*, as follows:

B	Gelatin, .....	10.0 grammes;
	Sodium chloride, .....	7.0 grammes;
	Distilled water, .....	500.0 c.c.

M.

Dissolve on a water bath; neutralize with decinormal sodium bicarbonate solution, and add distilled water to make the total volume measure 1000.0 c.c. The solution is sterilized in an autoclave at  $110^{\circ}$  C. for ten minutes, is then filtered into sterile flasks, when each flask is again sterilized for fifteen minutes in the autoclave.

**Collinsonia Canadensis.**—The physiological action of *Collinsonia canadensis* formed the subject of a thesis presented by M. Abal to the Faculty of Medicine of Paris for the doctorate degree (*Répertoire de pharmacie*, October, 1907). This plant contains a glucoside of the saponin type and a resin. The alcoholic extract of the root produces in small

doses nervous hyperexcitability. In larger doses this is followed by a depression, which may lead to a paralysis of central origin, with circulatory disturbances and symptoms of irritation of the glandular system. In moderate doses the glucoside acts as a feeble cardiac tonic, while the irritant effects predominate in large doses, giving rise in cold blooded animals to asystole, alternating with energetic systole. In warm blooded animals there is a rapid lowering of arterial pressure, with increased force of the heart beat. The resin acts less powerfully, but its action is to augment the action of the heart. It excites the secretions of the gastrointestinal tract and provokes a marked diuresis, probably owing to its action on both the circulation and the renal epithelium. All the elements of the urine are increased. The chief use of the drug is as a diuretic.

**Artificial Sera.**—The following formula is preferred by Netter (*Journal de médecine de Paris*, January 5th):

B	Distilled water, .....	1,000.0 grammes;
	Sodium chloride, .....	7.0 grammes;
	Calcium chloride, .....	0.20 gramme;
	Potassium chloride, .....	0.30 gramme;
	Sodium bicarbonate, .....	0.20 gramme.

M.

Bouchard employs the formula of Fleig, as follows:

B	Sodium chloride, .....	6.5 grammes;
	Potassium chloride, .....	0.3 gramme;
	Calcium chloride, .....	0.2 gramme;
	Magnesium sulphate, .....	0.3 gramme;
	Sodium bicarbonate, .....	1.0 gramme;
	Sodium glycerophosphate, .....	1.0 gramme;
	Glucose, .....	1.0 gramme;
	Sterilized distilled water, .....	1,000.0 grammes;
	Oxygen, sufficient to saturate.	

M.

**Treatment of Acute Catarrh of the Upper Air Passages in Children.**—In the acute rhinitis of infants Seiffert (*Deutsche medizinische Wochenschrift*, quoted in *The Practitioner*, January, 1908) gives an insufflation, two or three times a day, of a powder consisting of the following ingredients:

B	Boric acid, .....	5iii.
	Bismuth subnitrate, .....	5v.

M. ft. pulvis.

It is recommended to sprinkle the pillow several times a day with 10 to 15 drops of Hager's mixture, which has the following composition:

B	Carbolic acid, {	aa 5ii.
	Ammonia water, }	
	Alcohol, .....	5iiss.
	Water, .....	5iv.

M. ft. lotio.

Older children should inhale the vapor of camphor from a glassful of hot water, on which is sprinkled a pinch of powdered camphor. The steam should be inhaled through the nose by the help of a paper tube, and should be carried out for five minutes at a time thrice daily.

Of special value, the author says, is the use three times a day in a throat spray, or drop bottle, of twenty minims of the following solution:

B	Antipyrine, .....	℞. 8xx.
	Cocaine hydrochloride, .....	℞. xv.
	Distilled water, .....	5iii.

M.

Menthol vapor is of value in acute inflammation of the larynx and trachea: fifteen drops of a 10 per

cent. solution in olive oil should be used in a steam inhaler.

**Correction of Bromopnea Due to Gingivitis.**—The term bromopnea is suggested by Lederer (*Medical Record*, January 11th) to express the symptom of foetid breath, the term being derived from two Greek words, *bromos*, stench, and *pnoe*, breath. In foetid breath accompanying mild forms of gingivitis, Lederer says potassium chlorate or thymol and benzoic acid are good correctives. The following formulas are given:

B	Thymol, .....	gr. iv;
	Benzoic acid, .....	5ii gr. vi;
	Tincture of eucalyptus, .....	5iv;
	Alcohol, .....	5iii 5iii;
	Peppermint oil, .....	℥ xv.

M. Sig.: A teaspoonful in a glassful of water four times a day as a mouth wash (Miller).

If the gums are spongy, solution of aluminum acetate, well diluted, may be used as a mouth wash. Some recommend chlorine compounds, as:

B	Chlorine water, {	aa 5iv;
	Honey, {	
	Distilled water, .....	5x.

M. Sig.: Use as gargle.

An alkaline saponaceous tooth powder should be employed, the author recommending the following combination:

B	Saccharin, .....	gr. ii;
	Precipitated chalk, .....	5i;
	Powdered orris root, {	
	Powdered soap, {	aa 5ii;
	Sodium bicarbonate, {	
	Boric acid, .....	5i;
	Wintergreen oil, {	aa gtt. x.
	Peppermint oil, {	

M.

A pleasant deodorizing pellet, which, if slowly dissolved in the mouth, will mask bromopnea, is composed of thymol, menthol, eucalyptol, vanillin, and saccharin, of each, 1 milligramme (gr. 1/64).

**Powder for Seborrhæic Eczema and Rosacea of the Face.**—Unna uses the following powder applied lightly with a piece of old linen:

B	Zinc oxide, .....	5.0 grammes;
	Magnesium carbonate, .....	4.0 grammes;
	White bole, .....	2.5 grammes;
	Red bole, .....	0.5 gramme;
	Rice starch, .....	8.0 grammes.

M. Sieve frequently to make a very fine powder.

**To Allay Vomiting in Cancer of the Stomach.**—Robin (*La Quinzaine thérapeutique*, December 28, 1907) gives four to five drops of the following mixture in milk before each attack:

B	Picrotoxine, .....	0.05 gramme;
	Alcohol, .....	q. s.
	Morphine hydrochloride, .....	0.05 gramme;
	Atropine sulphate, .....	0.01 gramme;
	Bonjean's ergotin, .....	0.01 gramme;
	Distilled cherry laurel water, .....	12.0 grammes.

M.

**Liniment for Ulcerated Chilblains.**—The following formula is given in *Journal de médecine de Paris*, for December 20, 1907:

B	Purified shellac, {	
	Purified gum benzoin, {	aa 5iiss.
	Balsam of tolu, {	
	Carbolic acid crystals, .....	5iii;
	Oil of cinnamon, .....	5iiss.
	Saccharin, .....	5iiss.
	Alcohol, enough to make, .....	Oil.

M.

lishing Co., or by registered mail, as the publishers are not  
responsible for money sent by unregistered mail.Entered at the Post Office at New York and admitted for  
transportation through the mail as second class matter.

NEW YORK, SATURDAY, FEBRUARY 1, 1908.

THE COMMAND OF HOSPITAL SHIPS BY  
MEDICAL OFFICERS.

The controversy aroused by the order assigning a surgeon to the command of the hospital ship *Relief* has resulted in the publication of a series of documents bearing on the question which have been laid before Congress in compliance with resolutions calling for information on the subject. These documents show that on August 20, 1904, the medical officers of the navy were authorized to use the term "in command of." On May 5, 1906, general order No. 84 of the War Department was issued, publishing the report of the joint board of medical officers of the army and navy recommending that hospital ships be placed under the command of medical officers. This was accompanied by a comment from Surgeon General Rixey favoring the plan, and one from Rear Admiral Converse, at that time chief of the Bureau of Navigation, disapproving of it. A later memorandum from Surgeon General Rixey, a reply by Rear Admiral Brownson, his letter of resignation, the President's letters accepting this resignation, communications and orders relative to the commissioning of the *Relief*, the President's letter to the Secretary of the Navy condemning Admiral Brownson, and a communication from the surgeon general replying to the memorandum of Admiral Brownson have also been submitted to Congress.

A new element has been introduced into the discussion by Dr. Gallinger, a Senator from New Hampshire, who has submitted to the Senate a

memorandum showing precedents for placing surgeons in command of hospital ships. Among these precedents were a general order, issued February 6, 1865, placing hospital transports and hospital boats exclusively under the control of the medical department; five precedents from the Spanish-American war and nine from foreign naval history, while the *Army Regulations* are also quoted in which the command of army hospital ships is placed under the surgeon general of the army. The citation of these precedents by Senator Gallinger is most timely, as it furnishes a complete refutation of the most serious argument presented by Admiral Brownson against the order objected to, namely, that the issuance of such an order is illegal and contrary to all precedent in the service. Senator Gallinger's memorandum proves that it is not without precedent and has not been considered by the authorities as contrary to law.

We can scarcely understand the aversion with which the line officers seem to regard the plan of placing hospital ships under the actual command of medical officers, for, as was pointed out by Surgeon General Rixey, it is hardly conceivable that line officers would prefer to serve on a noncombatant ship in time of war, and even did they prefer to do so every one would be needed for active service on fighting ships. As a matter of fact, we have not enough trained officers to command all the auxiliaries even in times of peace, as there are at least half a dozen naval colliers now on the naval register which are manned by a "merchant complement," and a collier, unlike a hospital ship, is a vital part of the fighting machinery of the service. An enemy would gain no military advantage by the capture of a hospital ship, and we should not suffer material loss in efficiency. But the capture of a collier might determine a vital point of strategy at a critical stage of a naval campaign. It would surely be more important, therefore, that colliers should be commanded by line officers than that hospital ships should be.

The contention of Admiral Brownson that medical officers would not have authority over enlisted men and line officers who were on hospital ships as patients is disposed of by the general order of the Navy Department No. 61, August 20, 1904, authorizing medical officers of the navy to use the term "in command of," and by the universal practice in hospitals afloat or ashore, which places all patients while in the hospital under the command of the medical officer, regardless of the rank or station of the patient. In fact, it would be impracticable to carry on hospital administration successfully if the patients were not under the control of the hospital authorities.

Finally, it is most important that the neutrality of the hospital ship shall be maintained beyond all question, and this might prove difficult with a line officer in command of an enlisted crew. In fact, as pointed out by Surgeon General Rixey, the hospital ship *Solace*, while under the command of a line officer during the war with Spain, forfeited her title to neutrality on several occasions, and even laid claim to prize money for having taken part in offensive operations. On the whole we cannot but reiterate our conviction that the placing of a medical officer in command of a hospital ship was a wise move, and that, moreover, it is particularly desirable that hospital ships shall be maintained in commission during peace in order that both the officers and the men of the medical corps may become familiar with the details of service aboard such ships.

#### LONGEVITY AND THE MEDICAL PROFESSION.

Though length of years is not always an unalloyed blessing, many of us prefer to take our leave of life as the result of the ripening process so charmingly described by the late Sir James Paget rather than to be launched early upon the unknown waters of the future. We as physicians see a good deal of the misery of senility, and, as a consequence of the dreary contemplation, we are wont to say to ourselves that we had rather die while yet in possession of a reasonable degree of our natural powers than live on to be a burden to those who are younger than ourselves. But as old age creeps on us this feeling is apt to weaken, so that we cling to life in spite of our past sentiments.

Some men, on the other hand, cherish at all stages of their existence the desire of becoming centenarians. A few years ago there was formed in New York an organization known as the Hundred Year Club, the avowed purpose of which was to assist its members in attaining to advanced age. The membership, if our memory is not at fault, included a goodly proportion of medical men. And of late the versatile Metchnikoff has glowingly held out to his fellow professionals the prospect of prolonging life very decidedly. But it has long been known that physicians, as a rule, are not destined to longevity. Individual instances there are, to be sure, of medical men who have reached advanced age, and that, too, without notable impairment of their faculties. A striking example was the late Dr. Garcelon, whose venerable figure, still alert, was conspicuous in every meeting of the American Medical Association up almost to the time of his death. On the whole, however, physicians die com-

paratively young—younger, on the whole, than members of the other learned professions.

An interesting exposition of the subject was offered at a recent meeting of the Philadelphia County Medical Society, an account of which we print in this issue of the *Journal*. The topic of the particular diseases to which physicians seem to be prone furnished the opportunity for many a curious bit of medical biography. Especially noteworthy is the number of aneurysms with which Dr. Thomas King Chambers was afflicted. Addiction to drugs and the excessive use of alcohol, unfortunately, figure somewhat prominently among the causes of early death among physicians. Probably our professional brethren are naturally no more disposed to such dangerous violations of prudent living than other men are, and they certainly ought to profit by the many examples of their baleful action which come necessarily to their notice; but the responsibilities of medical practice, to say nothing of its almost constant interference with the practitioner's legitimate expectation of diversion, readily lead to indulgence for the sake of forgetfulness, and the narcotic drugs have for him a familiarity that tends to dull his dread of them.

#### MINOR MIDWIFERY.

A lecture entitled *Obstetric Nursing* was recently delivered before the Canadian Nurses' Association by Dr. David J. Evans, assistant obstetric physician to the Montreal Maternity Hospital. It is published in the January number of the *Montreal Medical Journal*, where it would not have found a place had it not contained hints as advantageous to the young physician as to the nurse. Indeed, much that is taught in nurses' training schools is well worthy of the medical novice's attention. This is not wholly due to the fact that the physician often has to manage even the minor details of a case single handed, being obliged to forego a nurse's assistance; if he does not know the nurse's duties as well as his own, he can hardly guide her intelligently when, as will occasionally happen, she betrays misapprehension or forgetfulness of some point in her training.

It is the little things that count in the general run of obstetrical practice. Real danger rarely attends childbirth, so a man may take no end of pains to familiarize himself with the technique of the Cesarean operation, for example, and yet fail to acquit himself creditably in managing the details of a simple delivery. We should have almost as keen an eye for a parturient woman's comfort and peace of mind as for her safety and that of the child. Not only is this a duty, but it will conduce most powerfully to that warmth of regard on the part of

patients which is so firm a support to the physician in his practice. The woman who has been thoroughly well taken care of in confinement cherishes for her physician a gratitude so deep that it arms him most effectually in his subsequent professional relations with the family. It is a hallowed feeling and a priceless one.

Almost as much may be said of the young mother's attachment to the skilled and conscientious nurse, and it is much to be regretted that many trained nurses seem averse to obstetric work. But perhaps their dislike for it is not entirely due to fastidiousness; the business aspect of an obstetric engagement is sometimes quite unfair to the nurse, she being expected to hold herself for a rather indefinite length of time in readiness to respond promptly to a hasty call, though entitled to remuneration only from the moment of her actual arrival on the scene. Such a state of things, as Dr. Evans points out, is all wrong. A soldier draws his pay and receives his maintenance in times of peace as well as when he is on the firing line, and so should it be with the nurse.

#### ACCIDENTS OF THE OCULAR REACTION TO TUBERCULIN.

The instillation of tuberculin into the conjunctival sac is doubtless a very convenient procedure for eliciting a reaction indicative of the presence of tuberculous disease somewhere in the body. It appears, however, that it is not always wholly free from danger, though it does not yet seem to have produced permanent ill effects. At a recent meeting of the Medical Society of the Paris Hospitals (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris*, December 12th), M. H. Barbier showed a boy, thirteen years old, who had been under treatment in his service for relapsing nephritis with anasarca, ascites, double pleural effusion, and signs of congestion of the apex of the right lung.

On the 10th of August, in M. Barbier's absence, a one per cent. solution of tuberculin was instilled into the right eye. On the same day there was an intense conjunctival reaction, with photophobia and lachrymation, which during the succeeding days was complicated with keratitis, with superficial ulceration, sufficiently intense to cause loss of vision in the eye. Early in September the left eye became affected in like manner, and the trouble remained stationary during the month. At the end of September M. Barbier resumed his service and found the child still the subject of decided lesions of both eyes, with very pronounced functional symptoms. The right cornea, completely cloudy, so as to prevent vision, presented ulcerations and pannus. The ocular con-

junctiva was red and oedematous. In the left eye there were the same lesions, but they were less intense.

Until the middle of October the child's eyes remained in about the same condition, with ameliorations followed by relapses. The right eye seemed to improve and the left one to be the more affected, though there was hardly any power of vision on the right side. Leucomatous exudates had appeared in both corneae. It was not until the end of October that the inflammatory phenomena had subsided and the exudates were beginning to be absorbed. Even then the right cornea showed diffuse cloudiness, with a central leucoma, but vision was somewhat improved. The improvement continued during the month of November, and the sight was finally restored, only two eccentric spots of opacity remaining. It is added that early in 1906 the child had had keratitis of a month's duration. M. Barbier is convinced that the tuberculous disease disclosed by the ophthalmic reaction is often latent, and he seems to question the advisability of resorting to the test in general.

At the same meeting M. Louis Rénon reported that in three instances out of twenty-eight trials of the tuberculin reaction he had observed accidents, plainly due to the employment of the test, for the patients had never before had any trouble with the eyes. In one of his cases there was intense conjunctivitis, lasting for forty-five days; in another there was slight keratitis; and in the third, twenty days after the reaction, there was extensive interstitial keratitis, with iritis, that lasted for more than three weeks, with adhesions which required the use of atropine and eserine to break them up. Possibly, he said, the use of a tuberculin solution weaker than one per cent. would not have been followed by untoward results.

#### THE INOCULABLE TUMORS OF MICE.

The successful inoculation of malignant tumors from man into the lower animals or from animal to animal is a necessary step in the solution of an ætiological problem which is at present attracting much attention. A great deal of work is being done at present on the carcinomata of mice, a number of tumors having been discovered which may be transplanted from mouse to mouse. Two of the best known of these are the Jensen tumor, which was reported in 1903, and the Ehrlich "Stamm II," reported in 1905, although there have been other tumors described which grow well upon being transplanted into healthy mice. Loeb and Hunter, in the laboratories of the University of Pennsylvania, have succeeded in inoculating a tumor, which was spon-

taneous in a mouse, into other mice with a good proportion of reproductions.

Among recent noteworthy contributions to the literature of the development of the Jensen and of the Ehrlich "Stamm II" tumors is a paper by E. E. Tyzzer (*Journal of Medical Research*, November). Tyzzer found that actively growing tumors developed in seventy three cases, 45.6 per cent., of transplantations of the Jensen variety in ten generations of mice. Sixteen per cent. of the actively growing tumors, however, disappeared spontaneously. In a few instances reinoculation of a mouse which had resisted a first inoculation was followed by the development of a tumor. There is no constant time ratio for the appearance of the tumor after the inoculation of the animal.

In the case of the Ehrlich "Stamm II" tumor ten transplantations gave fifty-nine actively growing tumors, 52.6 per cent., among the normal mice inoculated. In only one of these tumors was spontaneous retrogression observed. The tumors produced by the inoculation of both strains described are largely necrotic, because the growth of the epithelium is more rapid than that of the bloodvessels. Certain breeds of mice are found to be more susceptible to these tumors than other breeds. Metastases were found in connection with four of the transplanted Jensen tumors, all in the lung; and in two of the successful Ehrlich "Stamm II" inoculations, one in the lung, and one in the lung and the liver. The metastases are distinctly due to propagation through the bloodvessels. In no instance were the adjacent lymph nodes involved, although in some cases the tumor and the lymph node actually touched each other.

### News Items.

**American Climatological Association.**—The annual meeting will be held in Boston on June 9 to 11, 1908.

**Plague in India.**—During the week ending December 7, 1907, there were 4,500 cases of plague in India, with 3,430 deaths.

**Changes of Address.**—Dr. Joseph Kraner, from Bedford Station to 18 West One Hundred and Fourteenth street, New York.

**The Section in Ophthalmology of the College of Physicians of Philadelphia,** at its meeting held on January 10th, elected Dr. Howard L. Hansel chairman, and Dr. Edward A. Shumway, clerk.

**American Medicine Comes to New York.**—Beginning with the January number, *American Medicine*, formerly of Philadelphia, will be published at 84 Wallman street, New York, with Dr. Frank C. Lewis as managing editor.

**To Practise Medicine in Japan.**—It is stated on authority that foreign physicians who wish to obtain the right to practise medicine in Japan may pass the necessary examinations in English, French, or German, or may employ "the services of an interpreter."

**The Tri-County Medical Society of South Jersey,** comprising the counties of Gloucester, Salem, and Cumberland, held a meeting in Woodbury, N. J., on Tuesday even-

ing, January 28th. The paper of the evening, on Gas-troptosis, was read by Dr. Henry D. Beyea.

**New York Academy of Medicine.**—At a stated meeting to be held on Thursday evening, February 20th, Dr. Carlos F. MacDonald will read a paper on the Development of the Modern Care and Treatment of the Insane as Illustrated by the New York State Hospital System.

**Boston Society for Medical Improvement.**—The annual meeting of this society was held on Monday evening, January 27th. Dr. Charles W. Townsend read a paper on Congenital Pyloric Stenosis, and Dr. James S. Stone read a paper on Some Recent Literature on Intussusception.

**Women Graduates from the University of Michigan.**—Since the University of Michigan became a coeducational institution in 1871, 2,832 women have received degrees. Of these, 2,168 were from the literary department, 442 from the medical school, and 47 from the law department.

**The Tuberculosis Campaign in New York State.**—It is announced that the State Charities Aid Association has received from the Russell Sage Foundation the sum of \$10,000, to be used in carrying on the work of the educational campaign against tuberculosis, which was formally opened in Albany on Monday evening, January 27th.

**Fremont County, Colo., Medical Society.**—At the annual meeting of this society, which was held recently, the following officers were elected: President, Dr. C. H. Graves, of Canon City; vice president, Dr. W. R. Williamson, of Rockvale; secretary and treasurer, Dr. R. C. Adkinson, of Florence; delegate to State meeting, Dr. J. W. Rambo.

**New Training School for Nurses.**—It is reported that a nonsectarian training school for nurses will be established in connection with the Jewish Hospital, Brooklyn. The training course will be of two years' duration, and will be under the guidance of Miss Simonson, superintendent of nurses, and a corps of well known physicians and surgeons.

**Buffalo Academy of Medicine.**—The regular meeting of the Section in Obstetrics and Gynecology was held on Tuesday, January 28th. Dr. J. G. Clark, of the University of Pennsylvania, read a paper on Enteropitosis, and illustrated it by stereopticon slides. Dr. Earl Lathrop read a paper on the Management of Pregnancy and Some of Its Disorders.

**An Opening for a Young Physician.**—We are informed that in the town of Grafton, Rensselaer County, N. Y., there is no physician, the nearest one being at a distance of eleven miles from the town. The residents of Grafton are naturally anxious to have a physician establish himself in their town, and they believe that a good practice can be built up.

**The Philadelphia Medical Club.**—At the election held on January 18th, the following officers were chosen to serve for the year 1908: Dr. George McClellan, president; Dr. Wharton Sinkler, first vice president; Dr. James B. Walker, second vice president; Dr. J. Gurney Taylor, secretary; Dr. Lewis H. Adler, Jr., treasurer, and Dr. Oscar H. Allis, governor.

**The Health of Boston.**—According to the report of the Department of Health, during the week ending January 11, 1908, the following cases of transmissible diseases were reported: Tuberculosis, 41 cases, 28 deaths; enteric fever, 3 cases, 0 deaths; scarlet fever, 28 cases, 1 death; diphtheria, 60 cases, 3 deaths; measles, 69 cases, 3 deaths. There were 220 deaths from all causes in an estimated population of 560,892.

**Scientific Society Meetings in Philadelphia for the Week Ending February 8, 1908.**—Monday, February 3d, Philadelphia Academy of Surgery, Biological and Anatomical Section, Academy of Natural Sciences. **Tuesday**, February 4th, Philadelphia Medical Association; Northwestern Medical Society. **Wednesday**, February 5th, Academy of Physicians, Association of Clinical Assistants of Wills Hospital. **Thursday**, February 6th, Obstetrical Society; Medical Society of the Southern Department. **Section Meetings**, Friday, February 7th, Germantown Branch, Philadelphia County Medical Society, South County, 7th Avenue Philadelphia Medical Society, Kensington Branch, Philadelphia County Medical Society.

**Pure Food and Drug Law.**—It is reported that Professor Ira Remsen, of the Johns Hopkins University, has been asked by President Roosevelt to head the board of scientists who are to form a consulting committee on the enforcement of the pure food and drug law. The other members of the board will be chosen from Yale University, Northwestern University, the University of California, and the University of Virginia.

**Charitable Bequests.**—By the will of Alexander Crawford, the Northern Dispensary, of Philadelphia, receives \$2,300, and the Sheltering Arms, of Philadelphia, receives \$1,000. In the event of the death of a nephew without issue the Episcopal Hospital in Philadelphia will receive \$10,000 for the endowment of a free bed, to be known as the Ann Coleman Crawford free bed; the Northern Dispensary will receive an additional \$3,000, and the Sheltering Arms will receive an additional \$2,000.

**Medical Association of the Greater City of New York.**—A special meeting of the association will be held at the Staten Island Academy, Wall street, St. George, on Monday, February 3d, at 8:30 p. m., under the direction of the chairman for the Borough of Richmond. The programme will include a paper by Dr. Robert Abbe on Radium, and a paper by Dr. Reginald H. Sayre on the Modern Treatment of Bone Tuberculosis. A cordial invitation to the meeting is extended to all.

**A State Home for Inebriates in New York.**—At the annual meeting of the Medical Society of the State of New York, which was held in Albany, on January 28th, 29th, and 30th, a movement was inaugurated for the establishment of a State institution for the care of inebriates and persons addicted to the excessive use of drugs. A resolution recommending to the Governor and the Legislature the importance of such an institution was introduced by Dr. J. D. Spencer, of Watertown, and adopted by the society.

**Chicago and Suburban Health League.**—The first quarterly meeting of this organization was held on January 11th. The health officers in attendance were first taken to the isolation hospital for a practical demonstration in the diagnosis and treatment of smallpox, after which the meeting convened at the laboratories of the Department of Health. Dr. J. A. Lauer, of Whiting, Ind., read a paper on the Pollution of Water Supplies, and a discussion of the typhoid situation in surrounding towns followed.

**To Investigate Occupational Diseases in Illinois.**—The Governor of the State of Illinois has appointed the following physicians as members of the Committee of Nine, authorized by the General Assembly for the purpose of investigating occupational diseases in the State: Dr. Ludvig Hektoen, pathologist at Rush Medical College; Dr. George W. Webster, president of the State Board of Health, and Dr. James A. Egan, secretary of the State Board of Health. The committee will submit a report to the next General Assembly.

**Traveling Library for Health Officers.**—We learn from the Monthly Bulletin of the New York State Department of Health that for the benefit of health officers in the smaller communities to whom public medical libraries are not accessible the department has established a library from which books can be borrowed for a reasonable period. The number of books is limited, and on this account, for the present, those who borrow books will be restricted to not more than two at one time. If all copies of a book desired are out, a work on the same or an allied topic will be sent.

**First Aid Packet.**—The method of attaching the first aid packet issued to the Army, the Navy, and the Marine Corps, has been criticised as being impracticable. The metal case has also been criticised as soon becoming bright and furnishing an excellent mark for the enemy. The hooks provided for attaching the packet have been discarded by the Army, so that the packet may be slipped into a canvas pouch or pocket attached to the belt by hooks. It is understood that a similar change will be recommended by the medical department of the Navy.

**Dr. John Ordronaux's Bequests to Charity.**—Dr. John Ordronaux, who died recently in Roslyn, L. I., left about half of his estate of \$300,000 to charity. Dartmouth College, his alma mater, receives \$30,000 as an endowment; the Nassau, Jamaica, and Flushing Hospitals will each receive \$6,000 for the endowment of beds; the Methodist,

Presbyterian, and Catholic churches of Roslyn, and the Christ Protestant Episcopal Church of Manhasset will each receive \$3,000. Sums varying from \$1,000 to \$10,000 were left to various hospitals, churches, and charities.

**Seaman Prize Essays.**—The subjects for the essays in this competition are as follows: The Medical Department of the United States Army: Upon What Lines Should its Reorganization Be Instituted? for which a prize of \$100 is offered; The Company Noncommissioned Officer: How Can His Efficiency Be Best Promoted and His Reenlistment Be Secured? for which a prize of \$50 is offered. The terms of the competition may be obtained upon application to the Secretary of the Military Service Institution of the United States, Governor's Island, New York, N. Y.

**The Associated Physicians of Long Island.**—At the tenth annual meeting of this society, which was held on Saturday, January 25th, in the library building of the Medical Society of the County of Kings, Brooklyn, officers were elected to service during the ensuing year, as follows: President, Dr. H. Beekman Delatour, of Brooklyn; first vice president, Dr. Frank T. De Lano, of Rockville Centre; second vice president, Dr. Frank Overton, of Patchogue; third vice president, Dr. Thomas R. French, of Brooklyn; secretary, Dr. James C. Hancock, of Brooklyn; and treasurer, Dr. Charles B. Bacon, of Brooklyn. The general subject for discussion was Diseases of the Stomach and Duodenum, and papers on this subject were read by Dr. Algernon T. Bristow, Dr. H. Beekman Delatour, Dr. Richard W. Westbrook, and Dr. Walter C. Wood. The secretary reported that the membership of the society numbered 473 and applications were received every day. After the meeting the members adjourned to the Imperial, where a banquet was served.

**The Health of Philadelphia.**—During the week ending January 4, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Typhoid fever, 96 cases, 13 deaths; scarlet fever, 59 cases, 3 deaths; chickenpox, 51 cases, 0 deaths; diphtheria, 115 cases, 10 deaths; cerebrospinal meningitis, 2 cases, 2 deaths; measles, 74 cases, 3 deaths; whooping cough, 11 cases, 2 deaths; pulmonary tuberculosis, 74 cases, 72 deaths; pneumonia, 135 cases, 122 deaths; erysipelas, 5 cases, 3 deaths; German measles, 2 cases, 0 deaths; septicaemia, 1 case, 0 deaths; mumps, 9 cases, 0 deaths; cancer, 21 cases, 17 deaths; tetanus, 1 case, 1 death. The following deaths were recorded from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 7; puerperal fever, 1; diarrhoea and enteritis, under two years of age, 10. The total deaths numbered 688 in an estimated population of 1,532,738, corresponding to an annual death rate of 23.30 in 1,000 of population. The total infant mortality was 125; under one year of age, 96; between one and two years of age, 29. There were 50 still births—27 males and 23 females.

**Medical Society of the State of New York.**—At the one hundred and second annual meeting of this society, which was held in Albany on January 28th, 29th, and 30th, the following officers were elected to serve for the year 1908: President, Dr. Edward Trudeau, of Saranac; first vice president, Dr. A. G. Root, of Albany; second vice president, Dr. John Wheeler, of Chatham; third vice president, Dr. M. C. Hawley, of East Randolph; secretary, Dr. Wisner R. Townsend, of New York; treasurer, Dr. Alexander Lambert, of New York; chairman of the Scientific Committee, Dr. Leo H. Neumann, of Albany; chairman of the Committee on Public Health, Dr. J. L. Heffron, of Syracuse; chairman of the Committee on Legislation, Dr. F. Van Fleet, of New York; chairman of the Committee on Arrangements, Dr. W. J. Nellis, of Albany. The following named physicians were appointed delegates to the American Medical Association: For one year, Dr. Robert F. Weir and Dr. Charles Jewett; for two years, Dr. W. R. Townsend, Dr. D. C. Moriarty, Dr. C. B. Angell, Dr. J. C. Bierwirth, and Dr. Albert Vander Veer. The following named physicians were appointed alternate delegates to the American Medical Association: For one year, Dr. J. A. Fordyce, Dr. A. H. Terry, Dr. W. T. Mulligan, Dr. C. G. Rossman, and Dr. F. A. Burrall; for two years, Dr. Thornton, Dr. Brown, Dr. Little, Dr. Glass, Dr. Dunning, and Dr. Stover. Mr. J. T. Lewis was reappointed attorney for the society.

**The Philadelphia Pædiatric Society.**—The annual meeting of this society was held on Tuesday evening, January 14th. Dr. J. P. Crozer Griffith was elected president. Dr. Herbert B. Carpenter, Dr. J. Claxton Gittings, and Dr. Charles A. Fife were elected vice presidents. Dr. Howard Childs Carpenter was elected treasurer. Dr. Maurice Ostheimer was elected secretary recorder. The executive committee will be composed of Dr. D. L. Edsall, Dr. S. McC. Hamill, Dr. Alfred Hand, Dr. T. S. Westcott, and Dr. E. Franklin Royer, Dr. William M. Bradley, Dr. Eleanor C. Jones, and Dr. Frank Crozer Knowles were elected to the membership committee.

**New York Hospital for the Care of Crippled and Deformed Children.**—According to the seventh annual report of this hospital, which has just been published, in the hospital at West Haverstraw, N. Y., there were forty-eight patients on the first day of October. Of the twenty-two discharged during the year, ten were cured, nine were sent home much improved, two were removed by parents in opposition to the advice of the medical staff, and one died of meningitis. There is a waiting list of two hundred children. Plans for a new hospital, to accommodate four hundred patients, have been prepared, and the board of managers hope to receive an appropriation from Albany to aid them in carrying on the work.

**The Manila General Hospital.**—A new general hospital is being erected in Manila, which is located near the Bureau of Science. It is to be built on the most modern plan, and will consist of five two story wards, with a capacity of thirty beds in each ward, and there will be allowance in some of the pavilions for private patients, giving a total capacity of about three hundred beds. One special feature of the hospital will be an obstetrical ward for the training of medical students and midwives in the science and art of obstetrics. When this hospital is completed it is the purpose of the Government to cancel its contract with private hospitals and to merge the present Civil Hospital into the new institution.

**American Pharmaceutical Association.**—The Philadelphia Branch of this association will hold a meeting in the hall of the College of Physicians, Thirteenth and Locust streets, on Tuesday evening, February 4th, at eight o'clock. The general subject for discussion will be the Responsibility of the Retail Druggist in the Spread of "The Great Black Plague." This subject will be discussed from the viewpoint of the sociologist, the physician, and the pharmacist. The programme will include the following papers: The Relation of Medical Practice Acts to Contagious and Infectious Diseases, by Dr. Henry Beates, Jr.; Gonorrhea, Its Nature, Prevalency, Recognition, and Treatment, by Dr. A. A. Uhle; The Infection of the Innocent and the Suffering and Misery that is Entailed, by Dr. E. E. Montgomery; Gonorrhoeal Iritis and Its Relation to Total and Partial Blindness, by Dr. George E. de Schweinitz; and the More Remote Complications of Gonorrhoea in the Male, by Dr. Thomas R. Neilson. Many prominent physicians and sociologists have signified their willingness to take part in the discussion, and an interesting and instructive evening is assured.

**The Medical Society of the County of New York.**—A stated meeting of this society was held on Friday evening, January 31st. The retiring president, Dr. Walter Lester Carr, and the president elect, Dr. J. Riddle Goffe, delivered addresses, the subject of Dr. Goffe's address being The Life and Times of the Great Medical Reformer, Thomas Wakely, M. D., Founder of the London *Lancet*. The scientific session was devoted to a symposium on the recent epidemic of grippé, the following papers being read: The Scourge as it Appeared in Pittsburgh, by Dr. John A. Lichty, of Pittsburgh; Its Course in Baltimore, by Dr. C. Hampton Jones, of Baltimore; In New York, by Dr. Thomas Darlington; Its General Features and Peculiar Manifestations, by Dr. Alexander Lambert; Its Course in Children, by Dr. Charles Gilmore Kerley; Some Throat and Sinus Complications, by Dr. C. G. Cockley; The Ear Complications, by Dr. Edward B. Dench; Its Ravages in the Buccal Tissues, by Dr. William Carr. A general discussion followed. The officers of the society are as follows: President, Dr. J. Riddle Goffe; first vice president, Dr. H. Seymour Houghton; second vice president, Dr. John F. Weeks; secretary, Dr. John Van Doren Young; assistant secretary, Dr. J. Milton Abbott, and treasurer, Dr. Charles H. Richardson.

**The Southside Virginia Medical Association.**—At the December meeting of this association, which comprises the counties of Dinwiddie, Brunswick, Surry, Sussex, Prince George, Southampton, and Greenville, the following officers were elected for the year 1908: President, Dr. Lucien Lofton, of Emporia; first vice president, Dr. W. B. Barham, of Newsoms; second vice president, Dr. L. H. Moseley, of Ebony; third vice president, Dr. J. G. Rennie, of Petersburg; fourth vice president, Dr. C. W. Astrop, of Surry; secretary, Dr. E. F. Reese, of Courtland; and treasurer, Dr. O. C. Wright, of Jarratt. The association meets quarterly, and the next meeting will be held in Petersburg on the first Tuesday in March.

**The Philadelphia Neurological Society.**—At a meeting of this society, held on Monday evening, January 27th, the programme included the following papers: Unilateral Ascending Paralysis, by Dr. Alfred Gordon; Frenkel Treatment of Locomotor Ataxia, by Dr. M. D. Bloomfield; Card Specimen of a Case of Cerebrospinal Syphilis, by Dr. D. J. McCarthy and Dr. Milton K. Meyers; the Symptom Complex of Transverse Lesion of the Spinal Cord and Its Relation to Structural Changes Therein, by Dr. A. R. Allen. Dr. F. X. Dercum reported a case of Aphasia, Motor and Sensory, without a Lesion of the Third Frontal Convolution, and exhibited a specimen. Dr. W. G. Spiller presented a patient with Acquired Bilateral Spasticity and Athetoid Movements, and reported a case of Encephalitis with Symptoms of Cerebellar Tumor.

#### Society Meetings for the Coming Week:

**MONDAY, February 3d.**—German Medical Society of the City of New York; Utica, N. Y., Medical Library Association; Niagara Falls, N. Y., Academy of Medicine; Practitioners' Club, Newark, N. J.; Hartford, Conn., Medical Society.

**TUESDAY, February 4th.**—New York Academy of Medicine (Section in Dermatology); New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson County, N. J., Medical Association (Jersey City); Medical Association of Troy and Vicinity; Hornellsville, N. Y., Medical and Surgical Association; Long Island, N. Y., Medical Society; Bridgeport, Conn., Medical Association.

**WEDNESDAY, February 5th.**—Society of Alumni of Bellevue Hospital; Harlem Medical Association, New York; Elmira, N. Y., Academy of Medicine; Psychiatric Society of New York.

**THURSDAY, February 6th.**—New York Academy of Medicine; Dansville, N. Y., Medical Association.

**FRIDAY, February 7th.**—New York Academy of Medicine (Section in Surgery); New York Microscopical Society; Gynecological Society, Brooklyn; Manhattan Clinical Society; Practitioners' Society of New York.

**SATURDAY, February 8th.**—Therapeutic Club, New York.

**Philadelphia Bureau of Health Statistics.**—During the month of December, 1907, in the Division of Medical Inspection 3,670 inspections were made, exclusive of schools; 632 fumigations were ordered, 56 cases were referred for special diagnosis; 4,312 visits were made to schools; 482 children were excluded from school; 433 cultures were taken; 167 injections of antitoxine were given, and 342 persons were vaccinated. In the Division of Vital Statistics 2,546 deaths, 1,757 births, and 714 marriages were recorded. In the Division of Milk Inspection 7,698 inspections were made of 170,862 quarts of milk, of which 339 quarts were condemned. Seven specimens were examined chemically; 924 were examined bacteriologically, and 924 were examined microscopically. In the Division of Meat and Cattle Inspection 4,348 inspections; 198 were found unsanitary, and 128 pieces of dressed meat were condemned. Three hundred and three post mortem examinations were made, with 22 condemnations. In the Division of Disinfection 232 fumigations were done for scarlet fever, 548 for diphtheria, 79 for typhoid fever, 148 for tuberculosis, 170 for miscellaneous diseases, and 23 schools were disinfected. In the Bacteriological Laboratory 1,094 cultures were examined for the presence of bacteria; 288 specimens of blood were examined for the serum diagnosis of typhoid fever; 924 specimens of sputum were examined; 115 specimens of sputum were examined for tubercle bacilli; 6 distribution tests were made, and 2,780 quarts of antitoxine were distributed. In the Chemical Laboratory 17 analyses were made.

1. The Significance of Postoperative Acetonuria,  
By ERNEST BOVEN YOUNG and JOHN T. WILLIAMS.
2. Extracts from Dr. Alexander Hamilton's Itinerary of  
1744, By A. JACOBI.
3. Chyluria Due to Filariasis. With the Report of a Case,  
By RICHARD F. O'NEIL.
4. The Röntgen Ray Diagnosis of Urinary Calculus,  
By E. W. CALDWELL.
5. Trypsin in the Treatment of Malignant Tumors,  
By W. P. GRAVES.

1. **The Significance of Postoperative Acetonuria.**—Young and Williams state that acetonuria is a common accompaniment of a large number of pathological conditions, where it is the result of disturbances of metabolism. The occurrence of acetonuria seems to bear especial relation to disturbances of the gastroenteric tract, but possibly many of the cases of reported acetonemia following operation were the results of other diseases, especially sepsis. The formation and excretion of acetone, and probably also of its supposed antecedents, diacetic acid, betaoxybutyric acid, etc., following operation, is the result of altered metabolism and, in the adult at least, not the cause of any constitutional disturbance. The authors have made some observations on fifty-two patients, of whom only two, or about 3.8 per cent., had acetonuria before operation, while following laparotomy acetone was found in the urine of twenty-seven, or about 52 per cent. The reaction lasted in different cases from two to eight days. Of the two patients whose urine contained acetone before operation, one was a colored girl, fifteen years of age, who was operated upon for adhesions following an acute attack of pelvic inflammation. The operation was short and the convalescence excellent. The other was a woman of twenty-seven, who entered the hospital in very poor physical condition. A double salpingectomy was performed for pyosalpinx. Her convalescence was much prolonged, with rapid pulse, elevation of temperature, vomiting, and some mental somnolence, without any abdominal distention or spasm. She ultimately recovered. Out of the fifty-two laparotomies five patients died, and of these four had acetonuria. The duration of acetonuria varied from forty-eight hours in the majority to ten days. Of these patients, sixteen had subsequent laparotomies. In all but two the acetone had disappeared before the time of operation. In two others there was acetonuria on entrance and again after operation. In two a reaction was present on entrance, but not after laparotomy. In one of these, however, there was considerable vomiting, with rapid pulse and slightly elevated temperature, but terminating in recovery. In four there was a reaction after operation, but not on entrance; and in the remaining six no acetone was found either on entrance or after operation. It is seen that acetonuria occurred most frequently in those cases where there was more or less disturbance of metabolism, notably puerperal sepsis, hyperemesis gravidarum, miscarriages (many of which were septic), carcinoma, and eclampsia. And in those patients who may be supposed to have suffered from no disturbance of metabolism, namely, those admit-

ted for lacerations of the cervix and perinæum, retroversion fibroid of the uterus, and extrauterine pregnancy, it was found most infrequently. Acetonuria is much more common in children than adults. In children metabolism is much more active. The child has not only to replace the amount of tissue used up each day, but also to provide for growth. It is natural, then, that children should be more susceptible to changes of metabolism, and therefore that acetonuria resulting from disturbed metabolism should be more common in them.

4. **The Röntgen Ray Diagnosis of Urinary Calculi.**—Caldwell remarks that the Röntgen ray furnishes the most accurate single means we have for the diagnosis of urinary calculi. It has the advantage over other methods that it not only indicates the presence or absence of calculi, but their size, position, and number as well. When a small calculus is shown in the ureter, the size and shape of its shadow will sometimes enable us to predict that it will be passed, and that operation for its removal will be unnecessary. Occasionally, conditions other than lithiasis may be indicated, such as tuberculosis, abscess, and diseases causing a change in the size, position, or outline of the kidney, or a fibrous thickening of the lower part of the ureter. The x ray is not infallible, and in incompetent hands it may be very misleading, but under the best conditions it is exceedingly accurate. The indications given by it often decide the important question of operation. Such examinations should therefore not be undertaken lightly, nor intrusted to careless and incompetent persons, nor to those who have not a proper appreciation of the responsibility involved in deciding a question upon which may depend the health or even the life of a fellow being.

1. Factors Which Influence the Permanence of Cure in Operations for Cancer of the Breast,  
By WILLIAM D. HAGGARD.
2. The Appearance of Glycuronic Acid in Certain Conditions of Diminished Oxidation,  
By C. W. LEWIS HACKER.
3. Plea for a More Thorough Course in Practical Pharmacy and Prescription Dispensing in Our Medical Schools,  
By M. CLAYTON THRUSH.
4. Calmette's Ophthalmic Reaction to Tuberculin. Preliminary Report Based on Two Hundred and Forty-two Cases, By FRANK SMITHIES and R. E. WALKER.
5. Some Results from Orthodontia on the Deciduous Teeth,  
By E. A. BOGUE.
6. The Mutual Development of Upper Air Tract, Jaws, Teeth, and Face, and Their Economic Importance to the Human Race,  
By W. SOHIER BRYANT.

2. **The Appearance of Glycuronic Acid in Certain Conditions of Diminished Oxidation.**—Hacker remarks that in the first series of his examinations 384 samples of supposedly normal urine of patients in the hospitals of Albany were examined in the hope of finding a pseudoreaction, which is obtained by using a large amount of urine with Fehling's solution, and of connecting it with the presence of glycuronic acid or glycuronates. In no case could there be determined the presence of these latter compounds in amounts more than the normal or sufficient to render it of value for diagnostic purposes. Fourteen various samples of glycosuric urines were quantitatively examined, with the following results: Gerrard's and Fehling's

quantitative methods agreed to within 0.1 per cent. The results by the saccharometer were uniformly lower and usually by 0.1 to 0.7 per cent. This difference agreed, however, with surprising accuracy with that found in the polarization determination before and after fermentation. The figures obtained by subtracting the results of polarization before and after fermentation corresponded to saccharometer readings to within 0.1 per cent. These facts indicate that both quantitative copper tests include substances which are not dextrose and which turn the plane of polarized light to the left to the extent of from 0.1 to 0.7 per cent. (calculated as dextrose). The saccharometer readings do not include these compounds, hence they are not fermentable. It may be said that in these urines glycuronic acid or its salts was not present in excessive amounts. In the second series of examinations attention was turned to the postoperative specimens, in the hope that in the condition of diminished oxidation following anæsthesia glycuronates might be detected in abnormal amounts. All the samples were voided within twelve hours after operation. In all 273 specimens were examined, of which 261 were voided after ether anæsthesia, eleven following chloroform, and one after a mixture of the two. Examination of the urines previous to the operations showed no reducing compounds to be present. Subsequent to the operations eleven samples of urine, voided after ether, gave positive reductions with Fehling's test, and on further examination the reducing substance was shown to be dextrose in amounts from 0.2 to 1.3 per cent. The length and character of the operation apparently has no effect on the amount of dextrose eliminated. The patients were persons from twenty to thirty-five years of age. None of the chloroform samples or the chloroform ether sample resulted positively. This is probably to be explained by the use of oxygen during the operation, thereby preventing diminished oxidation in the tissues. The author concludes that dextrose appeared in 4 per cent. of 261 samples of urine collected after operations in which ether was employed. Neither glycuronic acid nor its conjugate salts are eliminated in the urine under conditions of diminished oxidation, such as occur during diabetes mellitus and ether or chloroform anæsthesia, when the latter is combined with oxygen. The pseudoreduction obtained in about 5 per cent. of normal urines is to be ascribed to faulty methods of performing the test. It is not due to an increase in amount of uric acid or creatinin.

4. **Calmette's Ophthalmic Reaction to Tuberculin.**—Smithies and Walker describe their experience with the Calmette ophthalmic reaction to tuberculin. They had 185 patients, clinically diagnosed as tuberculous cases; 176 of these gave positive reactions, nine negative; of twenty-eight doubtfully tuberculous cases twenty-one gave positive reactions, seven negative; of 188 persons suffering from disease not tuberculous, and including a fair proportion of apparently normal individuals, 180 gave negative reactions and only two were positive. The authors are convinced that the ophthalmic reaction as directed to be practised by Calmette and others is of undoubted service in the diagnosis of tuberculosis. In no case where its worth could be tested clinically by the finding of tubercle bacilli

did they fail to obtain decided ocular manifestations following the instillation of the tuberculin. This reaction did not follow when instillations were made in the case of 126 individuals affected with disease other than tuberculosis. It was not obtained in seventy-four apparently normal adults. A proper technique for administration is necessary for the success of the reaction. Whether or not smaller dosage would produce recognizable effects is not at present fully decided. Reactions have, however, been obtained when suspensions of 0.5 per cent. were used. When positive reaction follows promptly on the first instillation it appears that the diagnosis of tuberculosis is reasonably certain. The fact that a reaction thus appears does not mean that the subject is affected with an active tuberculous process, although the evidence is strongly in favor of such. Pre-supposing this might, in some instances, lead to unnecessary alarm and much inconvenience. The ophthalmic reaction, as is the case with every form of tuberculin test, must be accompanied by complete examination of the suspected focus in order to be judged properly. All suspicious cases which fail to respond to one instillation should be re-instilled from two to five times, and careful examinations, local and general, made after each instillation. Too little work has as yet been done to allow conclusions to be drawn regarding the relative value of the ophthalmic reaction and the subcutaneous or the skin reactions to tuberculin. In seven of their cases in which both the subcutaneous and ophthalmic reactions had been tried positive evidence was furnished in each case. They have had no experience with the cutaneous reaction. None of the reactions take the place of thorough examination of the patient, from every viewpoint. They are all confirmatory. Properly administered, they believe that the accumulation of more data will show that the ophthalmic reaction is quite as valuable to the general practitioner as are any of the others. Its convenience and rapidity of action certainly commend it. The hypothesis advanced by the authors is as follows: The inflammatory changes in the eyes of tuberculous individuals following the instillation of tuberculin suspensions is due to the slight stimulation of the hypersensitive cells forming protective substances, with the production of an excess of antibodies. These antibodies so produced, by acting on the tubercle bacilli or fragments of such enmeshed in the conjunctiva, liberate endotoxins which are capable of producing the inflammatory changes commonly observed.

#### MEDICAL RECORD.

By JAMES L. LEE.
8. A Case of Ectopic Gestation. Diagnosis and Operation Before Removal.  
By WILLIAM C. ALLEN.

2. **The Death Rate of the City of New York as Affected by the Cosmopolitan Character of Its Population.**—The conclusions to be drawn from Dr. Guilfooy's carefully prepared tables show that the natives of Ireland, by reason in great measure of their living at unfavorable age groups, increase the general mortality, and this is also true to a lesser extent of France, Switzerland, and Scotland; the natives of Italy, Bohemia, and the United States are credited with a rate almost the same as that of the general average of the city, while the natives of Sweden, Germany, Russia-Poland, Austria-Hungary, and England affect favorably the general mortality. On the other hand, the immediate descendants of the Irish, Italians, and Austro-Hungarians are instrumental in increasing the general rate and also the rate from certain preventable and infectious diseases; the immediate descendants of most of the other nationalities, including Americans, serve to lower the general rate. The last of his tables shows the death rate per 1,000 from certain diseases and all causes in selected square blocks typical of some of the nationalities and races, the population of these blocks numbering from 1,400 to 5,100 inhabitants, and are situated in congested areas of the city. 1. The Negro block.—The influence of the negro's presence upon the mortality rates is always cumulative and is clearly shown in the table; the general rate, 38.56 per 1,000, of the selected negro block (San Juan Hill) is more than double that of the city at large; the rate from pulmonary tuberculosis is three and a half times that of the average for the city and is only exceeded by that of the Chinese block; the mortality from organic heart, chronic Bright's, pneumonias, and diarrhoeal diseases is also excessively high; throughout the greater city the mortality among the colored population is 27.16 per 1,000, as against one of 18.19 among the whites, the general death rate being 18.35, the effect of the negro population being to increase the rate by 0.16 of a point. 2. The Syrian block.—The general rate of 35.83 per 1,000 almost equals that of the negro block, and the mortality from cancer, pneumonia, and diarrhoeal diseases is greater than that of the negro. 3. The Chinese block contains about 1,450 Chinamen and is noted as the block with the highest death rate from pulmonary tuberculosis, as well as for its unsavory police record; the general rate is 34.65 per 1,000, and it also shows a rate from pneumonia almost as high as that of the Italian block. 4. Irish block shows a high general death rate and a high rate in all diseases preponderating at middle or advanced ages. 5. Bohemian block shows a moderately high general death rate and excessively high rate from pulmonary tuberculosis and organic heart disease. 6. Italian block shows a general rate slightly above the average but the highest rate from the pneumonias. 7. Russian-Polish block shows a low general rate with a pneumonia death rate somewhat above the average. The low rates in the Jewish block and throughout the city can be ascribed to several causes; although living in densely populated sections, the Jew, by reason of his temperate habits and his inherited vitality, is able to resist and overcome infection; or, as has been said of the Jew, he is physically "tough" in its best sense; again, the pres-

ent status of the Jew as to age distribution is favorable at most age periods, with the exception of under five years. 8. The Austro-Hungarian block makes a very presentable showing. 9. The German block shows the lowest general death rate, the only rate much above the average being that from cancer.

4. **Chancroidal Bubo and Its Treatment.**—Morton, of Brooklyn, advocates the following treatment, which was suggested to him by a visit to the Charité in Berlin: When a bubo first appears, an attempt should always be made to prevent suppuration by putting the patient to bed. The ice bag is no longer used, because it has been found that resolution will take place just as well with warm applications. Injection into the substance of the gland of antiseptic solutions has also been abandoned as useless. The bubo is covered with gauze, wet with 95 per cent. alcohol, and with cotton wadding and perforated gutta percha tissue to prevent too rapid evaporation. The alcohol is renewed twice a day as it evaporates. Another method is fomentation with solution of ammonium acetate used warm and frequently renewed. Tincture of iodine has little or no value as an absorbent. After fluctuation has begun the warm applications should be changed for hot ones, to encourage rapid breaking down of the glands. The thermolyte bags are useful, as they can be used with the hot fomentations and serve to retain the heat for a long time. After the bubo is thoroughly broken down and full of pus, a small incision is made with a double edged knife and the pus evacuated. A 10 per cent. iodoform glycerin emulsion is then injected into the wound. The injection is made three times at the first sitting, the first two injections being allowed to run out and the last one retained. The wound is then bandaged over night with fomentations of solution of ammonium acetate. On the following day the bubo is emptied by squeezing out and the injection is again made. The wound is then bandaged and left undisturbed for five or six days. At the end of that time, in the great majority of cases the bubo is healed and the patient requires no further treatment.

8. **A Case of Ectopic Gestation.**—Dukeman describes such a case and states that his diagnosis of probable tubal gestation was based on the following points: 1. The cessation of menstruation the month previous in a healthy woman; 2, the character of the pain penetrating and radiating toward the heart and the anxious manner in which the patient described the pain; 3, slight hæmorrhage for a couple of days, accompanied by the peculiar pelvic pains, which then ceased; 4, tenderness over the left pelvic wall.

#### BRITISH MEDICAL JOURNAL

January 11, 1908.

1. Hospital Treatment of Morbid Pregnancies, By J. W. BALLANTYNE.
2. The Bacteriological Aspects of the Problem of Neurophatic Keratitis, By H. M. DAVIES and G. HALL.
3. A Plea for the Improvement in the Teaching and an Encouragement in the Study of Legal Medicine, By J. J. BUIST.
4. Cancer, Its Ætiology and Treatment by Trypsin, By J. ALCINDOR.
1. **Morbid Pregnancies.**—Ballantyne advocates

the establishment of what he calls "prematernity" beds in maternity hospitals, which beds should be strictly reserved for the reception of cases of morbid pregnancies. Such beds should be placed in a ward by themselves and should be in charge of a nurse or nurses who have had surgical and medical as well as obstetrical experience. Special attention should be paid to urine analysis, to examination of the blood and nervous system, to ophthalmoscopic investigations, and to a detailed and thorough examination of the signs and symptoms of pregnancy, including estimations and descriptions of the foetal heart and of the foetal movements. Suitable cases for treatment in prematurity beds are pregnant patients suffering from albuminuria, heart disease, intractable vomiting, pulmonary disease, hepatic disease, anæmia and other blood disorders, and various nervous maladies, especially epilepsy, hysterocleptisy, hysteria, chorea gravidarum, and paralysis. Diseases of the reproductive organs themselves, such as retroversion of the gravid uterus, threatened abortion, pruritus and oedema vulvæ, uterine prolapse, cystocele, vulvar inflammation and abscess, uterine myomata as complications of pregnancy, and suspected ectopic gestation, might all very properly be treated in prematurity beds. The same is true of hydramnion and overdistension of the uterus (twins), and suspected cases of hydatid mole, placental hæmorrhage, missed abortion, or antenatal death or deformity. Further patients who have suffered in past pregnancies from "habitual" abortion, "habitual" foetal death or disease, "habitual" prematurity or postmaturity, or from eclampsia, might there be suitably treated in order, if possible, to prevent the recurrence of these reproductive disasters. Cases unsuitable for treatment in such a prematurity bed are those of infectious fevers (scarlet fever, measles, typhoid, erysipelas) occurring as complications of pregnancy, and those of insanity in pregnancy. It is doubtful whether cases of syphilis should be dealt with, but patients suffering from gonorrhœal vaginitis and vulvitis might be taken in and treated during their pregnancies. Alcoholism and dipsomania in pregnant women might be regarded as suitable for treatment, but actual delirium tremens should find a home elsewhere until the acute stage has passed off.

2. **Neuropathic Keratitis.**—Davies and Hall have studied the ætiology of neuropathic keratitis, paying special attention to its bacteriology. Its intimate relationship to disturbances of the fifth nerve and Gasserian ganglion has led to the eye changes in all cases being considered as secondary to the morbid condition or disturbance of the Gasserian ganglion. Among the various hypotheses may be mentioned the following: Purely trophic, trophic with central irritation, trophic with peripheral irritation, vasomotor, vasomotor traumatic, purely traumatic, and desiccation. Finally there is the mycotic hypothesis, looking on microorganisms as an ætiological factor. This is the one most favored by the writers. They investigated twenty-one cases of neuropathic keratitis, and found a certain organism, called by them the *Bacillus x*, to be present in the conjunctival sacs of all. The organism could be demonstrated, together with staphylococci, among

the epithelial cells at the margin of the ulcer of the excised eye. This same bacillus was found in about 30 per cent. of normal people, but it was not found in those cases which did not develop keratitis after removal of the Gasserian ganglion. The writers conclude that the presence of the *x* bacillus in the sac is necessary for the production of neuropathic keratitis, but that it does not cause it unless there is an associated lesion of the Gasserian ganglion. Even in the latter case the disease does not develop if the eyelids are sewn together, or if the disease is already present. It tends to heal rapidly after suture of the eyelids. So that for the production of neuropathic keratitis three factors must be present: (1) Removal of the Gasserian ganglion; (2) the presence of the bacillus; and (3) a factor of undefined nature dependent on the eyelids and removed by closing them. (1) and (2) are not adequate alone, as suture of the lids prevents or cures neuropathic keratitis; (1) and (3) are not adequate alone, as keratitis only occurs after destructive lesions of the Gasserian ganglion when the organism is present and in the same proportion of patients as that in which the organism occurs in normal persons.

4. **Cancer.**—Alcindor holds that the predisposing factor in malignant disease is lowered vitality, whether due to faulty metabolism, alcoholism, overstimulation, disease of trophic nerves, or the debilities, local or general. Chronic irritation, of no matter what character, is the determining factor; the cells of the tissue irritated, unable to respond normally to the irritant, assume characteristics suitable for their environment, thus conforming to a natural law. Trypsin is of considerable value in cancer. Cancer of the cervix of the uterus, rodent ulcer, and epithelioma are eminently suitable for the treatment. Gout, rheumatoid arthritis, and chronic rheumatism ought to be treated by injections of trypsin when other better known methods have failed. Amylopsin, either alone or in combination with trypsin, is of no value in the treatment of cancer.

8. Sudden and Complete Inversion of the Uterus: Its Probable Causation, By A. MAUDE.
9. On Blood Coagulability in the Puerperal State, By R. H. FOX.

1. **Bacilluria in Childhood.**—Box classifies infections of the urinary tract in children as (1) descending infections, (2) ascending infections, and (3) infections by contiguity. Descending infection

is synonymous with infection carried to the kidney by the blood stream, and is therefore termed "hæmatogenous." But, while descending invasion does undoubtedly occur, yet the common cause of bacilluria in children is an ascending infection. The commonest form is that which is due to the colon bacillus. Although the disease may occur in males, it is much more common in females, which is strong corroborative evidence of its ascending character, for the shortness of the female urethra and the proximity of its orifice to the anus render infection easy. In babies infection through the urethra may occur from soiled napkins or from the passage of stools over the vulva. Infection of the urinary passages in childhood may manifest itself as pyelitis, cystitis, or incontinence of urine without obtrusive evidence of local inflammation. Pyelitis may occur as a febrile affection with sudden onset, chills, and pyrexia. When the course of the disease is protracted emaciation rapidly occurs. Enlargement of the spleen may often be detected, and sweating may be pronounced. As a rule, the local manifestations of the disease are unilateral, and the right kidney is more apt to be affected than the left. Slight vulvitis is present in some cases. Incontinence of urine if often associated with bacilluria, and the organism present is almost invariably the colon bacillus. The reaction of the urine is generally faintly acid, never alkaline. The prognosis of these colon infections must be guarded, as they may drag on for months. Frequent bathing and the avoidance of urethral contamination from the anus are important preventive measures. Full doses of potassium citrate combined with the sedatives of the belladonna group often act well, but belladonna is disappointing in inveterate cases. The writer has tried antibacillus coli serum in two cases of incontinence. In one the serum stopped the incontinence, though the bacilluria persisted. In the other the serum had no effect.

2. **Cancer.**—Brand discusses the causation and infectivity of cancer. Among the new facts discovered about cancer in recent years are the following: 1. The mitosis of the cells of malignant neoplasms has been found to be heterotype in character, whereas the mitosis of all somatic cells with one exception, and of the cells of benign tumors, is homotype. The mitosis of normal reproductive tissue is also heterotype. 2. It has been discovered that cancer is not restricted to the higher vertebrata, e. g., man and the domesticated animals, as was at one time supposed, but that it occurs in all vertebrata, with the possible exception of certain reptilia. The malignant growths occurring in other vertebrata are identical with those found in man, clinically, pathologically, anatomically, and microscopically. 3. The transmissibility of malignant new growths from one lower animal to another of the same species has been demonstrated. The writer enumerates two final syllogisms: 1. All diseases which are infectious to the individual are transmissible to others. Cancer is infectious to the individual. Therefore cancer is transmissible to others. 2. All diseases which are infectious to the individual have an external origin. Cancer is infectious to the individual. Therefore cancer has an external origin.

4. **Ferments.**—Ransome discusses the mode of action of organized and unorganized ferments

and their relationship to one another. Fermentations may be grouped under two heads—first, those in which microorganisms are always present, and, secondly, those in which the specific agent is unorganized. In the first group are included (1) all the organisms concerned in the production of fermented liquors; (2) the microorganisms producing various eruptive, contagious, and noncontagious diseases, such as scarlet fever, measles, diphtheria, malaria, sleeping sickness, and the various epizootics. In the second group are (1) all the physiological ferments; (2) those bringing together the components of essential oils and dyes; (3) those which assist in the ripening of fruits; and (4) the unorganized derivatives of living ferments. The enzymes produced by living organisms have been grouped under the following heads: (1) Proteolytic, (2) diastatic, (3) inverting, (4) coagulation, and (5) sugar splitting. One of the most important attributes of ferments in general is the specificity.

6. **The Alkaline Earths.**—Nias has studied the hæmostatic action of the alkaline earths, and concludes that none come up to the lactates and chlorides and carbonates if duly assimilated, and that we should rely on these for the treatment of hæmophilia. For urticaria and conditions of general debility there is perhaps a larger selection.

9. **The Blood in the Puerperium.**—Fox records observations made by him on the coagulation time of the blood in the puerperal condition. He finds the coagulation time immediately after delivery is below the normal, but not markedly so. Under careful management of labor the hæmorrhage is less and the blood coagulability is less altered. In every case in which two successive observations were taken the coagulation time increased during the interval. The excretion of calcium salts in the milk tending to reduce the coagulability of the blood was probably one cause of this increase. An observation of the coagulation time of the blood after delivery might give useful warning of the risk of thrombosis or embolism if the coagulation time were low, or of post partum hæmorrhage if it were high. Appropriate treatment—for example, with citric acid on the one hand or with calcium lactate and salines on the other—would rectify the condition.

1. Oxidation of Sugar, By G. ROSENFELD.
2. Concerning Micrococcus Influenza, Infectious Allorhythmia of the Heart and Nycturia, with Observations Concerning Pyocyanosis, Quinine, Gas Baths, and the Action of Acids on the Organism, By BIEDERT.
3. Experiences with the Meningococcus Serum in Cases of Cerebrospinal Meningitis, By W. SCHULTZ.
4. Symptomatology of Tumors of the Brain, By H. HIRSCHFELD.
5. A Case of Diffuse, Fœtid, External Otitis in a Telephone Operative, By HAMM.
6. Concerning Suboccipital Inflammations (Concluded), By L. GRÜNWAUD.

3. **Meningococcus Serum in Cases of Cerebrospinal Meningitis.**—Schultz reports a case of cerebrospinal meningitis in which he unsuccessfully injected Kolle-Wassermann's meningococcus serum and compares statistics he has collated thus: Of twenty-three patients treated with serum thirteen died, a mortality of 56.5 per cent. Of forty-one patients not treated with serum twenty-two died, a mortality of 53.7 per cent. Hence he is of the opinion that we are not yet in a position to combat satisfactorily epidemic cerebrospinal meningitis with Kolle-Wassermann's serum.

4. **Symptomatology of Tumors of the Brain.**—Hirschfeld reports two cases which demonstrate beautifully the difficulties met with in making a diagnosis of brain tumor. The first case was one of a large adenocarcinoma of a cerebellar hemisphere with three smaller, similar tumors, one extracerebral and two intracerebral, in a woman, sixty-three years of age, who presented a great multiplicity of symptoms. The second case was one of a symptomless tumor of the hypophysis, aneurysm of the carotid at the sella turcica, and proliferating endarteritis of the small vessels of the brain in a woman thirty-six years old.

5. **External Otitis in a Telephone Operative.**—Hamm reports a case of diffuse, fœtid, external otitis met with in a telephone operative, which he is inclined to ascribe to the effect of the electric current.

6. **Suboccipital Inflammation.**—Grünwald adds another case to those reported in the first part of his paper and then presents the following conclusions: 1. Suboccipital inflammation is dependent not only on tuberculosis of the occiput and vertebra, but may be induced by other inflammatory processes, such as diseases of the ear, traumatic diseases of the base of the skull, particularly diseases of the accessory sinuses, also of the teeth, and finally syphi-

lis. 2. The suppuration calls forth various symptoms according to the course which it takes and the organs it involves, but under all circumstances it causes certain typical symptoms. 3. Among the most marked, or at least most important, of such symptoms should be mentioned the more or less extensive opisthotonos together with the early commencement of the pains localized in the region of the trigeminus or occipitalis as particularly characteristic. It is, therefore, to be recommended, without going further into the nomenclature, to unite all these processes under the title of suboccipital inflammations and to consider more closely only the origin and course. 4. In the late stage the infiltrate in the nape of the neck points to the seat of the inflammation. Perforation into the retropharyngeal space is less characteristic. 5. The original focus can be recognized often only from the course of the symptoms as regards time and place, because one and the same localization can have either primary or secondary importance. The focus may remain latent for a long time. 6. The closest attention should be paid to symptoms of perforation, sudden diminution of the pain, of the fever, and the motor disturbances, because these correspond to the extension to a larger region of the hitherto closely circumscribed process, and so in any given case point out the final moment when, by an immediate operation, an unlooked for or even fatal result may be avoided. 7. A careful study of the temperature is particularly useful not only to watch the course but also to enable us to recognize this critical moment in which the extension commences. 8. Before the development of marked suppuration the attempt is justified to secure a retrogression of the process by absolute fixation of the head.

11. The Medical Service in the Road Construction from Daraasalam to Morogoro, By KRAUSS.
12. The Stand Taken by Josef Gossmann in regard to Professional Ethics, By KRECKE.

2, 3, and 4. **Cutaneous and Eye Reactions to Tuberculin.**—Mainini asserts that (1) the cutaneous as well as the ophthalmoreaction is positive in persons with positive tuberculosis with great constancy, with the exception of very advanced cases; (2) the specificity of this reaction is probable for many reasons, though not yet proved; (3) in indi-

viduals not suspected of tuberculosis the cutaneous reaction has perhaps a six times higher value than the ophthalmoreaction; (4) under the assumption that the reaction is specific this contradiction appears that the ophthalmoreaction points to an active tuberculosis chiefly, while von Pirquet's reaction indicates rather a latent focus.—Wiens and Günther state that they obtained in a number of cases very serious changes in the eye from the instillation of a 1 per cent. solution of tuberculin as recommended by Calmette, and allege that this procedure is not so harmless and unimportant as has been supposed.—Klieneberger investigated the ophthalmoreaction of tuberculin in sixty-one cases, nine tuberculosis, six suspicious, and forty-six presenting no clinical signs of tuberculosis. All of the nine tuberculous cases reacted positively to the second instillation, even those in whom the reaction to the first instillation had been negative or doubtful. The second reaction was more severe in the mild cases than in the serious ones, and was milder than the first in only one case. Very severe inflammatory symptoms appeared in one case of pulmonary tuberculosis. Of the six suspicious cases only two reacted positively to the repeated instillation. These had reacted slightly to the first, but the second was more pronounced. Of the forty-six cases in which there was no clinical evidence of tuberculosis, thirty-six reacted positively to the second instillation, 78 per cent. Twenty-eight of these presented no trace of reaction to the first instillation, while in the others the first reaction was weak or questionable. The severity of the symptoms induced by the second instillation was marked, as a severe conjunctivitis was induced in sixteen of this group by the repeated instillations. In five there was a considerable swelling of the lids, diffuse hæmatoma, and chemosis of the conjunctiva, conditions which rendered necessary a long course of treatment. Klieneberger will not grant that there was latent tuberculosis in 78 per cent. of the persons who presented no clinical signs of the disease, and hence concludes that reaction from repeated instillations is of no clinical value. He considers the reaction to the second instillation as one of hypersensitiveness and not serviceable for diagnostic purposes.

5. **Antitoxic Function and Albumin.**—Much gives a detailed account of his experiments and suggests three possibilities to account for his results, the most probable of which he believes to be that antitoxine is not albumin, but that the separation of the antitoxic function from the albumin which cannot be brought about in the test tube is accomplished in the milk glands.

7. **Albuminuria and the Excretion of Salicylic Acid.**—Ehrmann finds that in normal persons without acute or chronic arthritis the urine remains free from albumin after a single dose of 5 grammes of sodium salicylate. In a few cases a very slight ring of albumin appeared, which disappeared after a day or two. Repeated doses of 5 grammes usually produced no albumin. In the few in which a ring of albumin appeared at first it disappeared as after a single dose, in spite of repeated doses. In patients with acute and chronic arthritis the same was true. In them, likewise, when albuminuria was caused it disappeared again in spite of repeat-

ed doses. He found also that the period of the greatest excretion of salicylic acid did not coincide in time with the appearance of albumin. He finds the duration of excretion to be from thirty-six to forty-eight hours. The real dangers of treatment with salicylic acid he believes are not to be found in its action on the kidneys, but in its effect upon the brain and spinal cord.

1. Concerning the Antiferment Reaction of the Blood and its Relations to the Opsonic Strength in Acute Infectious Diseases, By WIENS.
  2. Withdrawal of Common Salt in Hydrops of Pregnancy, By CRAMER.
  3. Concerning Pancreon, By FISCHER and HOPPE.
  4. Alternating Appearance of Purpura Rheumatica and Erythema Exudativum Multiforme Hebræ, By VÖRNER.
  5. Late Appearing Lesion of the Ulnar, By BRASSERT.
  6. Casuistic Contribution to the Question of the Prognosis After Swallowing Foreign Bodies with Unfavorable Surfaces, By FISCHER.
  7. Extragenital Infection, By KNAUER.
  8. Pruritus in Tabes, By GÜNZBURGER.
  9. Contribution to the Innovations in the Field of Obstetrical Instruction on the Phantom, By GLÖCKNER.
  10. Tamponade of the Nose and of the Nasopharyngeal Space, By LENNHOF.
  11. Narcosis with Warmed Chloroform, By RATH.
2. **Withdrawal of Common Salt in Hydrops of Pregnancy.**—Cramer says that he has obtained excellent results in hydrops of pregnancy by confining the patient to a diet from which salt was carefully excluded. Such foods as meat and milk, which naturally contain considerable salt, were forbidden. Wine and beer were allowed in moderate quantities, and no special limit was placed on the amount of fluid to be drunk. The prescribed diet is given as tea, coffee, malt coffee, lemonade from the fruit juice with ordinary water, rice, coarse meal, sago, potatoes, farinaceous foods, puddings, green vegetables, lettuce, fresh or cooked fruits, two eggs a day, bread made without salt, and fresh butter from which the salt has been washed. Any addition of salt to the food is forbidden, but any spice may be added for the sake of improving the taste. The women are able to attend to their daily duties during this course of treatment.

3. **Pancreon.**—Fischer and Hoppe seem to consider pancreon to be a food particularly well fitted to meet the needs of patients suffering from mental and nervous diseases.

4. **Alternating Appearance of Purpura Rheumatica and Erythema Exudativum Multiforme Hebræ.**—Vörner reports a case in which he observed the alternation of these two conditions at intervals of fourteen days in a boy ten years old. He believes that the same etiology underlies both.

5. **Late Appearing Lesion of the Ulnar.**—Brassert reports the case of a man, forty-eight years of age, who came under observation during the autumn of 1907 on account of atrophy of the muscles of the right hand, which are supplied by the ulnar. The elbow joints showed thickenings and deformities, and could not be perfectly extended or rotated, a condition which was more marked about the right elbow. This condition was referable to abscesses about the elbow joints following scarlet fever in 1875. No other explanation of this muscular atrophy could be discovered than the involvement of the ulnar nerve in these changes.

about the joint, the symptoms referable to it having appeared at the end of nearly thirty-two years.

**6. Prognosis After Swallowing Foreign Bodies.**—Fischer reports a case in which a child, ten months old, passed per rectum an open safety pin which had been swallowed about four weeks previously.

**7. Extragenital Infection.**—Knauer reports a case of chancre of the finger.

5. A Ten Years' Study of Cupar Water Supply (Clatto Waterworks), with Special Reference to the Germ Content thereof,  
By C. E. DOUGLAS.

**5. A Ten Years' Study of Cupar Water Supply, with Special Reference to the Germ Content Thereof.**—Douglas describes the water supply of Cupar-Fife, a burgh having about 4,500 population, which is obtained from a gathering ground at Clatto, about five miles distant in a south-easterly direction, 600 feet above sea level and about 500 feet above the mean level of Cupar. The supply is an upland surface water, obtained from numerous "feeders" from the neighboring higher levels, the land being cultivated, some of it arable, the rest pasture land. The gathering ground itself has a water surface, when full, of about 820 acres of catchment area, and gives a supply of 280,600 gallons per day; there is, therefore, a supply about six gallons per head of the population. The soil is of the limestone formation. The water is purified by sand filtration. The filtering medium consists of washed quarry clips at the bottom, covered by clean washed gravel, assorted into five degrees of fineness from the size of hazelnuts to such as will pass through a sixteen mesh sieve and be retained by a sixty-four mesh sieve. Altogether this gravel bed is two feet in depth. Two feet of clean washed fine sand overlay this bed. When the filters become clogged the top is scraped off and laid aside. This is allowed to weather thoroughly, and is then well washed in a mechanical sand washer acting under a head of water; it can be used again indefinitely. Each filter is usually cleaned once in six weeks, the indication for this being the lowering of the level in the clear water cisterns into which the water passes immediately after filtration. When the slime layer on the surface of the filters becomes too thick, the water cannot pass through so quickly as to maintain the level of the water on the filter, and the filter in question has then to be cleaned. The total filtration area, when all filters are in use, is 1214 square yards. With the average daily flow of water this gives 272.65 gallons per square yard of filtering area per twenty-four hours, equal to 1.26 gallons per square foot per hour—in other words, a filtration speed of only 4.848 feet in twenty-four hours. After filtration, the water passes through

a seven inch pipe to a small reservoir three miles nearer Cupar, which contains always about a day's supply, 300,000 gallons or thereby. The author made a thorough examination of the water and came to the conclusion, that the water in a catchment area may differ chemically from that of the underlying geological formation. The Glenfield scraping process is of value in maintaining the output of a supply pipe at its proper figure, and may even save a community the very large cost of putting down a new supply pipe. The apparatus used consists of a machine which is driven through the pipe by the pressure of the water. There are two distinct portions of the machine, the front portion carrying a pair of steel scrapers, working one behind the other, and being connected by a swivel joint with two steel propelling pistons also working one behind the other. This apparatus is put into the pipe at a manhole just below the filters, and driven down by the force of the water behind it till it emerges at the next manhole situated about a mile further down. During its passage it has to be most carefully followed by the men in charge. They have previously located the line of the pipe by auscultation through a long iron stethoscope, and indicated its track by a series of little flags. If the scraper is travelling, its progress can be detected by the low grinding noise made by it in encountering the incrustation. While it is travelling the detached incrustation goes down before it. Sometimes it becomes fixed. The increased pressure of the water behind it may overcome the obstruction. If not, it has to be cut down upon and started once more. The range of alkalinity observed in this water supply does not appear to have any effect upon the germ content. The mean germ content of this upland surface water is between 900 and 1,000 per c.c. The method of sand filtration is capable of removing over 90 per cent. of organisms when the filters are in good working order. Filter beds should be cleansed about once in six weeks, and should be allowed at least a week's rest after cleansing before being put again into use. The germ content of a water supply is distinctly greater at the point of delivery than as issuing from the filter bed, and this increase is probably due to the state of comparative rest in the pipe. In an upland surface water the number of organisms which will grow at blood temperature is a very small proportion of those growing at room temperature.

#### Proceedings of Societies.

##### COLLEGE OF PHYSICIANS OF PHILADELPHIA

##### Section in General Medicine.

March 1, 1908.

The President, Dr. A. O. J. KELLY, in the Chair.

**Primary Cancer of the Head of the Pancreas Causing Obstructive Jaundice.**—Dr. HERMAN B. ALLEN reported the case of a man, SIXTY-FIVE years old, who was admitted to the Philadelphia Hospital complaining of jaundice, epigastric pain, headache, and weakness. The jaundice had developed two weeks before admission, and gradually deepened to

a mahogany tint. The liver was enlarged, and the gallbladder enlarged and distinctly palpable, but not tender. The urine always contained bile, and the fæces were generally alcoholic and contained fat. No tumor could be felt in the epigastrium. The patient died of exhaustion and toxæmia. The whole duration of his illness was less than two months from the onset of the jaundice. At autopsy there was found primary cancer of the head of the pancreas causing jaundice by compression of the common duct.

The author discussed the diagnosis of cancer of the head of the pancreas from stone in the common duct, from stone in the ampulla of Vater, and from cancer of the duct and cancer of the duodenum occluding the orifice of the duct.

With regard to the special tests for pancreatic digestion, such as Sahle's and Schmidt's, the author had found them uncertain if not misleading. An excess of fat in the stools was of value in diagnosis, particularly if there was a small quantity of soaps in proportion to the neutral fats and fatty acids. But an accurate estimate of these fats was not easy. In the work of Robson and Commodge the authors reported an analysis of the fæces for fats in twenty-four cases of malignant disease of the pancreas. The average percentage of total fats was 77, of neutral fats 50, and of fatty acid 27. But the percentage of total fat varied between 93 and 40 per cent., of neutral fat between 69 and 31, and of fatty acid between 36 and 3 per cent. Such wide variations must lessen the value of the findings in any case. Commodge had also reported upon the result of his improved pancreatic reaction in sixteen cases of cancer of the pancreas. It was positive in only four, negative in twelve cases.

Dr. J. DUTTON STEELE believed the estimate of the fat percentage to be the only accurate means of determining between jaundice due to obstruction of the duct and jaundice due to other causes.

**Congenital Torticollis.**—Dr. ARTHUR NEWLIN reported this case, which was attributed to lateral fixation of the head in the pelvis during uterine life.

Dr. H. A. HARE inquired whether tests had been made of the muscles of the opposite side of the neck to show whether the torticollis might not be due to lack of power or to palsy of the opposite side.

Dr. NEWLIN replied that these muscles had been examined, but not by electrical apparatus. Apparently they were normal.

**Some Clinical Aspects of Blood Coagulation.**—Dr. THOMAS R. BOGGS, associate in medicine in the Johns Hopkins University, presented this paper, saying that the coagulability of the blood was dependent upon a number of different factors. It might be varied experimentally *in vitro* and *in vivo* by modifying the physical and chemical condition of the blood. From the standpoint of the practitioner, it was possible, with a fair degree of accuracy, to measure the gross variations in coagulability and in some cases to modify this coagulability by therapeutic measures.

For increasing the coagulability the most useful means was the administration of calcium salts by the mouth, subcutaneously, or by direct infusion. The salts best adapted to this purpose were the ace-

tate and lactate of calcium. In general, many cases of hæmorrhage from parenchymatous tissue (capillary hæmorrhage) after trauma, in purpura hæmophila, scurvy jaundice, etc., might be benefited by calcium therapy.

The treatment was as yet purely empirical, and not all cases of the same disease would show identical conditions with regard to coagulability or respond in the same way to treatment. Nevertheless, the number of cases which were benefited was sufficient to make it desirable to extend the study of coagulation from a clinical standpoint.

Dr. HARE thought it the experience of all who had employed the calcium salts in the various conditions in which Wright had recommended them had been bitterly disappointed at times, and at other times had gained results as encouraging as the disappointments had been discouraging. Possibly 75 per cent. of the employments of the calcium salts in his hands had been futile, while in 25 per cent. some good had been observed.

#### PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of December 11, 1907.

The President, Dr. JAMES B. WALKER, in the Chair.

**Diseases of Physicians.**—Dr. ROLAND G. CURTIN presented a résumé of his experience in the study of diseases of medical men, with a tabulation of the cases and remarks upon the frequency of diseases, some of which were unusual and some more common. The probable cause was given, also the mode of life necessary to preserve health, with directions tending to prolong the practitioner's life, especially in old age. The statistics given did not embrace slight ailments or any of the severe forms of disease in which Dr. Curtin had been called in consultation. His findings in regard to the drug habit among physicians differed from the conclusions of Dr. Crothers, of Hartford. The showing of twenty-eight deaths from angina pectoris bore out the appellation of "doctors' disease" for this affection. Only four cases of Bright's disease had been noted, all of a severe type. The milder ones were not mentioned. Ten cases of renal calculus had been found. The cause of this large number was difficult to explain. At least half the number were in young practitioners.

A general study showed that clergymen had twice the chance to attain the age of sixty-five than the physician had. This was accounted for by the constant stress attendant upon the physician's life. The motor car was said to add greatly to the strain of the nervous system.

**The Longevity of Physicians.**—Dr. JOSEPH P. TUNIS showed that the mortality of the medical profession was higher than that of many other occupations. According to Dr. Ogle's statistics, the farmer was the longest lived, and the clergymen enjoyed the greatest longevity of the learned professions. The late Dr. George M. Beard, in 1866, had said that the greatest and hardest brain workers of history had lived longer, on the average, than brain workers of ordinary ability and industry. Beard had found that the average age at death of 500 of the greatest men in recorded history was 64.2. From an insur-

ance point of view, physicians had shown a slightly greater mortality than had been expected. Taking them as a whole, they were, however, "average risks."

*Mortality Table of Physicians at Different Periods.*

Year.	No. Investigated.	Investigator.	Mortality.
1834.....	624	Casper	56.4
1885.....	3,865	W. Ogile	59.3
1886.....	8,627	J. M. French	56.47
1907.....	2,000	J. P. Tunis	60.6

The author concluded that statistics proved the truth of the popular belief that all men lived longer nowadays than fifty years ago; that the most satisfactory statistics of longevity could be secured only by selecting groups of men living under the same conditions; that the diseases to which physicians were especially liable affected the cardiovascular and nervous systems; and that the secret of long life would seem to lie in abstemiousness, brain work, and contentment, a sound mind in a sound body being presupposed.

**Diseases of Great Physicians of the Past.**—Dr. WILLIAM PEPPER pointed out the difficulty in drawing conclusions as to the commonest forms of disease in the physicians whose names were mentioned, as it was only in those cases in which the men had suffered from some interesting disease that the cause of death was given. The cases were, however, classified according to certain loose groups, the most interesting group including those who had described diseases and had themselves suffered from the same disease. Another group included those who had fallen victims to various diseases in the line of their duty.

Laennec fell a victim to a disease the nature of which he had taken pains to describe. Lancisi and Corvisart died of diseased heart, Boyle sank under the ravages of the disease of which he had been the most successful illustrator. Sir Benjamin Brodie, a great surgeon, died of cancer of his right shoulder joint. Dupuytren, the most famous surgeon of the last century, died of an empyema. Refusing to submit to an operation, he said he "would rather end his life through God's hand than that of a surgeon."

In more recent times Mikulicz, who wrote on cancer of the stomach, himself fell a victim to this disease. Fowler, of Brooklyn, having written on appendicular inflammation, died of this disease.

Upon the memorial tablet of Dr. Jesse W. Lazear, who died of yellow fever, were the words: "With more than the courage and devotion of the soldier he risked and lost his life to show how a fearful pestilence is communicated and how its ravages may be prevented."

A number of distinguished physicians had been great sufferers from the gout. Sydenham said: "More wise men than fools are victims of this affection."

Angina pectoris had claimed its share of the medical profession, and in this group might be mentioned the names of Sir James Y. Simpson, Sir Charles Bell, and John Hunter.

Instances were cited illustrative of Osler's statement that the profession offered many examples of good work thoroughly and conscientiously carried out by men with aneurysm of the aorta. Dr. Thomas King Chambers first had an aneurysm in the

left popliteal artery, eleven years later one in the right leg, cured by pressure, and finally aneurysms of the carotid arteries. Dr. Richard Bright died of the consequences of extensive and long standing calcification of the aortic valves of the heart, the exit for the blood being reduced to a mere chink. Robert Liston died of an aneurysm of the aorta, which must have existed for years and been fostered by his great physical exertions, which characterized his recreation as well as his work.

Another group was given, including those having suffered from apoplexy, and still another and larger group was classified under the heading of miscellaneous.

Dr. JAMES C. WILSON said there were two main groups of morbid conditions to which physicians were particularly liable—the infectious diseases of adult life and the general diseases of the period of involution of life, diseases especially of the cardiovascular system, of the kidneys, and of the nervous system. Neurasthenia, the drug habit, and alcoholism were also to be considered. These were said to be the result largely of improper living combined with inherited feebleness of organism. The man who entered upon the practice of medicine with impaired powers of resistance and lack of self discipline was apt to become neurasthenic or fall a victim of one of the drug habits.

Dr. JAMES M. ANDERS, commenting upon the frequency of cardiovascular degenerations among physicians, thought that the experience of any single physician or group of physicians even could not solve the problem, since individual experiences differed widely. As pointed out by Dr. Tunis, physicians lived under different conditions, pursued different lines of professional work, and their habits were equally various. He held, however, that it was possible to accumulate a sufficiency of data on which to base valuable practical conclusions.

An analysis of 115 cases showed tuberculosis to be present in nearly 15 per cent., while organic heart disease, gout, obesity, and neurasthenia stood next in point of frequency. Angina pectoris, diabetes mellitus, and nephritic colic, conditions which appeared to lead in Dr. Curtin's experience, were less common, although, when compared with their incidence in general, the percentage among physicians was still abnormally large.

The cases of angina pectoris, nephritic colic, and diabetes occurred among men who might be counted as brain workers, but they also led unusually sedentary lives and were given to the pleasures of the table. Of morphinism in doctors there were five cases, which result agreed with Dr. Curtin's statistics rather than with those of Dr. Crothers. It was remarked, however, that morphine was often used in secret by physicians.

Dr. Anders felt strongly that an extensive statistical inquiry would reveal sufficient facts and data upon which to base valuable conclusions. The subject was said to be one bringing up the whole question of the influence of occupation as a causative factor of disease, which, whether considered in relation to the professional crisis, brain workers in general, merchants, artisans, clerks, or laborers even, was not fully appreciated by the medical profession.

Dr. DAVID ROEMAN referred to a French case

valent among the laity that physicians had no right to be ill, and regarded it as probably a relic of the superstition of the barbaric age, when disease was looked upon as a demon that could be exorcised by the medicine man, who, naturally, if he could drive it out of the patient, would drive it out of his own body. Instances were cited of disease contracted in the course of the work of physicians. Whether physicians were prone to certain diseases could only be learned by statistics. Dr. Riesman's own practice showed that of some diseases there is a rather large number of cases of physicians. He had had seven cases of appendicular inflammation, two of tuberculous disease of the lungs, two of pneumonia, ten of neurasthenia, four of arteriosclerosis, and a number of others, one and two of a kind. Arteriosclerosis seemed to be quite common. Two of his patients had been under thirty-five years of age and total abstinents in regard to alcohol. Loss of sleep and the use of tobacco were considered productive factors. His experience showed neurasthenia to be rather profound in the medical profession. While it could not be said that physicians were exempt from disease, it was believed that they would work longer when handicapped than any other class of men, because of their sense of responsibility and the fact that no one could take a doctor's place.

Dr. JAMES TYSON had seen a good many physicians with typhoid fever. He had very often been consulted for morphinism by physicians who realized their complete helplessness. He had also known cases in which physicians had most successfully overcome the habit. The cocaine habit in his experience has been a very frequent occurrence among physicians. This habit was much more easily overcome than morphinism. Of angina pectoris he had seen a number of cases. Two cases were cited showing the impossibility of drawing conclusions of a prognostic character from the symptoms. The presence of albuminuria and casts in the case of a physician who had been very much overworked, but which passed away almost immediately upon rest, was a condition falling under his observation. Neurasthenia he regarded as almost a doctor's disease, stating that, after women, doctors came in as a class of neurasthenics.

Dr. JAY F. SCHAMBERG regarded the strain and stress under which the physician lived and his exposure to contagious and infectious diseases as essential factors in the varying incidence of certain diseases in the medical profession compared with the general population.

He referred to the fact that Dr. Edward Jenner had been the first to call attention to the pathological cause of angina pectoris and refrained from publishing his views on the subject during the lifetime of John Hunter, because of his intimacy with his friend and teacher; and, although he made known his views to the physicians of Hunter, he was only given credit for his knowledge after Hunter's death, when these gentlemen found calcification of the coronary arteries.

Dr. ALBERT R. MOULTON, from his experience with cases of drug addiction, was inclined to believe that the percentages given by Dr. Crothers of the drug habit among physicians were exaggerated.

Dr. CURTIN noted that, in fifteen deaths from

angina pectoris among physicians, five had occurred suddenly after a hard day's work and a hearty meal. He suggested that the heaviest meal should not be taken at night and that the physician should rest, if tired, before and after the meal. After the age of fifty it was important that physicians gradually reduce their work, avoiding night work and shortening that of the day.

Dr. PEPPER said that as the historian of the evening he would simply refer to that good old physician Rabelais, who, after his study of this subject, said that "there be more old drunkards than old physicians."

## Letters to the Editors.

### RECOVERY FROM CANCER.

470 COMMONWEALTH AVENUE,  
BOSTON, December 31, 1907.

To the Editors:

The writer desires information regarding any alleged recoveries or cures of inoperable or recurrent carcinoma of the mammary gland. If any case or cases are known to any one who reads this circular and can be authenticated by facts as to the history and condition prior to recovery and the length of time which has elapsed since recovery, such information will be much appreciated and duly acknowledged. Any well authenticated reports of recoveries from carcinoma located in other parts than the mammary gland will be welcomed. Cancer paste cures, x ray cures, radium cures, or cures as result of surgical operation are not wanted. Hearsay cases are not wanted unless accompanied by name and address of person who may give knowledge first hand.

HORACE PACKARD.

### MELANCHOLIA.

NEW YORK, January 18, 1908.

To the Editors:

In the *Journal* of October 12th is an editorial on melancholia in which are reviewed the work and conclusions of Dr. G. L. Dreyfus, of Heidelberg. You say in your editorial that Dr. Dreyfus, "after reviewing all the cases in Kraepelin's clinic, comes to the interesting conclusion that involution melancholia—the only melancholia in the Kraepelin system—is but a phase of manic-depressive insanity."

In my *Textbook of Nervous Diseases and Psychiatry*, 1904, I distinctly taught this view, and I argued for its soundness in a paper read before the New York Neurological Society over three years ago.

There could be nothing less ambiguous than the following paragraph (p. 641): "Melancholia, strictly speaking, is a special disease, and occurs under three forms: (1) Acute melancholia; (2) chronic melancholia; (3) manic-depressive insanity, or manic melancholia. These are all closely allied types, so much so that the term 'manic-depressive psychosis' might also be used to include all three." My conclusions were not guesswork, either, but based on a study of several hundred cases.

A particular point in my paper was that the melancholia of involution was not always one of the later period of life, but had its representation in

certain usually mild anxious depressions of early or middle life, and in the hypochondriasis of adolescence and later. There is no clouding of consciousness in those cases, and the depressive ideas relate usually to subjective or bodily symptoms.

This form of melancholia, in its milder types called by Meyer "anxious depression," is rather rare in early life and increases in frequency to the age of fifty. There is a form of it which is characterized by extreme activity of thought, unclouded brain, great fixity of delusion, and a most persistent impulse to suicide. Here the delusions are usually self accusatory and do not relate to bodily conditions.

The most sharply separated form of melancholia is, no doubt, the depressed phase of manic-depressive insanity. Here there is not so much depression or actual psychic pain as there is apathy, slowness and difficulty of thought and action, so that the patient may become almost stuporous. Yet there are linking cases which show the relationship between this and other forms of melancholia. For purposes of convenience, then, I think we can recognize: 1. Acute melancholia, which is represented by the type just described and which may alternate with a mania. It is often recurrent and occurs oftener in early life, but it also runs well into old age. 2. Chronic melancholia, often a melancholia of involution, but not always, and called as Meyer suggests an "anxious depression" at whatever period of life it occurs. A type of this may be called "agitated depression," which takes in the active and suicidal cases of early and later life, and the "anxious depression" includes most of what is usually called hypochondriasis. This form is seen with increasing frequency as age comes on. There are linking cases, and certain fundamental symptoms appear in each group.

CHARLES L. DANA.

### Book Notices.

*Metabolism and Practical Medicine.* By CARL VON NOORDEN, Professor of the First University Medical Clinic, Vienna. Volume III. The Pathology of Metabolism, by Carl von Noorden, H. Salomon, A. Schmidt, A. Czerny, H. Steinitz, C. Dapper, M. Matthes, C. Neuberg, O. Loewi, and L. Mohr. Anglo-American Issue, under the Editorship of I. Walker Hall, Professor of Pathology, University College, Bristol, etc. Chicago: W. L. Koenner & Co., 1907. Pp. xx+527 to 1320. (Price, \$6.)

This, the third and concluding volume of von Noorden's great work on the physiology and pathology of metabolism, comprises the sections of greatest practical interest for the physician. The two preceding volumes, on the physiology and general pathology of metabolism, have already been reviewed in this journal. In the third volume are considered the important relations of the chemical changes in the body to various specific diseases, including diabetes mellitus, gout, obesity, diseases of the skin, cancer, the gastrointestinal diseases of children, myxœdema, Graves's disease, acromegaly, and Addison's disease. There are also valuable and suggestive chapters on mineral waters, baths, drugs, and poisons, and the influence of light and the

Röntgen and radium rays. One is impressed by the enormous amount of patient and minute research work reported and sifted in these volumes, by the frank note of scientific candor in the recognition of the incompleteness and often conflicting nature of the results obtained by equally competent and unbiased observers in the same field, and by the meagreness of the therapeutic applications which may be deduced in most cases from laboratory conclusions alone.

And yet the difficult studies, which are only in their infancy, have already cleared the ground of many traditional fallacies and superstitions, and are the only certain basis for the hope of a therapy more rational than a blind empiricism. Among the positive benefits to clinical medicine which may fairly be alleged for the exact methods of modern researches in the chemistry of normal and pathological physiology are the recognition of the rôle of the acetone group as a cause of the acidosis producing diabetic coma, the part played by the purin substances in the dietetic management of gout, and the detection of the rarer derangements of carbohydrate oxidation which result in such anomalies of excretion as pentosuria and the presence in the urine of glycuronic acid and lævulose, inositol, maltose, and other unusual forms of sugar. Studies in metabolism have also profoundly changed our views as to the action of many drugs and as to the therapeutic use of mineral waters. On this latter point von Noorden pertinently and justly says: "Valuable scientific work has, however, been published during the last ten years in spite of the enormous output of worthless, pseudoscientific writings which mislead the inexpert. A clamorous jargon has been invented, which includes apparently learned expressions about delayed or increased metabolism, oxidation, assimilation, protein balance, molecular disintegration, ions, osmosis, radioactivity, and the like; without these no twentieth century advertisement is complete. The truth is that so little is known of the bearing of mineral waters on biological processes that most of the statements in balneological literature may be stigmatized as idle make believe." This quotation is a fair example of the author's impatience with pretense, and his demand for rigorous demonstration can not but have a stimulating and wholesome influence upon the medical reader, although at times some of his cherished beliefs may receive a rude shock. Nothing is more futile than theory without an adequate basis of carefully observed fact, and one obstacle to advancement is removed when we freely admit our ignorance of what we do not know.

"Eine einziger Zahl hat mehr wahren und bleibenden Wert als eine kostbare Bibliothek voll Hypothesen."

*Commercial Precedents.* Selected from the Column of Replies and Decisions of the *New York Journal of Commerce and Commercial Bulletin*. An Essential Work of Reference for Every Business Man. By CHARLES PUTZEL, A. B., LL.B., of the New York Bar. Hartford: American Publishing Company, 1907. Pp. v-770.

This volume presents a compilation of the questions and answers concerning commercial law and usages which have appeared in the pages of the *New York Journal of Commerce and Commercial Bulletin*. This journal has for seventy-five years been

the leading authority in the field of commerce, and the department which has been known in it as Replies and Decisions has always been regarded as one of its most valuable features. The publication is in no sense a law book, the underlying principles on which the opinions and decisions are based not being elaborated. The book contains much information regarding commercial law and usage which will be of interest to every one, whether engaged in professional or in commercial pursuits.

*Thinking, Feeling, Doing.* By E. W. SCRIPTURE, Assistant Neurologist to Columbia University. London and New York: G. P. Putnam's Sons, 1907.

The author, after twelve years, has given us a second edition of this excellent little manual. It is one of the clearest of similar works and introduces the reader at once into the mysteries of the mechanism of mind action in a delightful and satisfying manner. It has had a great success as a textbook, and in its new edition merits all the attention it has been paid in the past.

#### BOOKS, PAMPHLETS, ETC., RECEIVED

Movable Kidney and Other Displacements and Malformations. By David Newman, M. D., F. F. P. S. G., Surgeon to the Glasgow Royal Infirmary, etc. New York, Bombay, and Calcutta: Longmans, Green & Co., 1907. Pp. 233.

Transactions of the American Gynecological Society. Volume 32. For the Year 1907. Philadelphia: W. J. Dornan, Printer, 1907. Pp. 568.

#### Miscellany.

**International Congress on Tuberculosis.**—Active preparations for the International Congress on Tuberculosis, to be held in Washington, next September, are under way in other countries. The national committees for France, Germany, Sweden, Austria, Holland, Greece, Bulgaria, Cuba, Venezuela, Brazil, and Costa Rica have organized and have forwarded their membership lists to the secretary general. The French committee has a membership of over 300 and includes men of prominence in public life as well as in the medical profession. The officers of this committee are: President, Dr. Louis Landouzy, of the medical faculty of the University of Paris; vice presidents, Dr. Faisans, of the University of Paris; Professor Vallée, veterinarian, of Alfort; Dr. F. Bezancon, of the University of Paris, and Dr. Le Gendre; secretaries, Dr. Triboulet, secretary general of the last International Congress, which was held in Paris three years ago; Dr. Nobecourt, Dr. Leon Bernard, Dr. Dehan, and Dr. Georges Bourgeois; treasurer, M. Masson. The secretary of the German committee, Dr. Johannes Nietner, was secretary general of the recent International Congress on Hygiene and Demography. Other members of the committee are Dr. Gotthold Pannwitz, secretary general of the International Tuberculosis Association; Dr. B. Frankel, Dr. Ernst von Leyden, professor emeritus of the University of Berlin, and Dr. Johannes Orth, professor of pathology in the University of Berlin. Dr. N. P. Tenderloo, of Leyden, another well known pathologist, is a member of the committee for Holland. Dr. P. K. Pell, of the University of Amsterdam, is chairman of that committee, and Dr. W. J. von Gorcum, of The

Hague, is the secretary. Dr. A. Herrera Vegas, the chairman of the Venezuelan committee, is president of the Venezuelan Antituberculosis League and a member of the National Academy of Medicine at Caracas. Dr. P. Acosta Ortiz, the vice president, is a director of the hospital at Vargas, and Dr. L. Razetti, another member of the committee, is vice rector of the University of Venezuela, and permanent secretary of the National Academy of Medicine. All of the members of the Brazilian committee are actively identified with the antituberculosis movement in that country. The committee includes Dr. J. J. Azevedo Lima, of Rio Janeiro, president of the Brazilian Antituberculosis League; Dr. Oswaldo Cruz, director general of the Department of Public Health; Dr. J. J. Seabra, and Dr. Cypriano de Freitas, of Rio de Janeiro. The president of the Cuban committee is Dr. Guiteras, formerly professor of pathology in the University of Pennsylvania, and now at the University of Havana. Dr. J. L. Jacobsen, the vice president, is president of the Cuban Antituberculosis League. The secretary is Dr. M. G. Lebre-do, of Havana. Two well known members of this committee are Dr. Aristides Agramonte, the last surviving member of the famous yellow fever commission of the United States army, and Dr. Carlos J. Finlay. Dr. B. Patrikios, the chairman of the committee for Greece, is secretary of the Department of Health of Greece, and secretary general of the Greek Red Cross Society. Dr. Aristote Kouzis, the secretary, is a professor of the University of Athens. Dr. Constant Savas, a member of the committee, is professor of hygiene in the University of Athens; Dr. P. Manoussos is the principal medical director of the Military Hospital at Athens, Dr. Kalliontzis is professor of surgery, and Dr. Pierre J. Rondopoulou is professor of pathology at the University of Athens. The Hon. Otto von Printzkold, the chairman of the Swedish committee, is the first chamberlain of the Swedish court. The secretary, Dr. Bertil Buhre, is the president of the Swedish Antituberculosis League, the largest volunteer association of the kind in existence. The Costa Rican committee has named Dr. Louis P. Jimenez chairman, and Dr. Teodoro Picado, of San José, secretary. Other members are Dr. Teodoro Prestinary, Dr. Benjamin Hernandez, and Dr. Marcos Zunega, all of San José. Three chairmen have been named by the Austrian committee. They are Professor Leopold von Schrötter, of the medical faculty of the University of Vienna; Dr. Weichselbaum, and Dr. Richard Paltauf, of the department of pathology of the University of Vienna. The secretaries are Dr. H. von Schrötter, Dr. L. Teleky, and Dr. J. D. Bartel. Dr. M. Rousseff, director of the Department of Health of Sophia, is president of the Bulgarian committee; Dr. Ivan Ognianoff, secretary of the Superior Board of Health at Sophia, is secretary, and the members include Dr. Georghi Zolotovitch, Dr. Ivan Theoroff, and Dr. S. A. Valcovitch.

**A Case of Acquired Dextrocardia Associated with Advanced Phthisis.**—J. Hubert Young, of Boston, places a case on record (*Boston Medical and Surgical Journal*, December 12, 1907) which is unique, as the patient was continually under observation during the transposition of the heart from left to right. This displacement was gradual, and,

as it became more marked, signs of cavity were elicited at the right apex. There were no subjective symptoms referable to the heart, and, except for rare intervals when the patient was confined to her bed for a day or two, with slight gastric disturbance, she was dressed and about the ward all the time without any discomfort. Nor was there any clinical evidence that the heart was not performing its function perfectly in its abnormal position. X ray examinations were made, but, owing to the involvement of the right lung, the right border could not be accurately determined. About twenty-five cases of acquired dextrocardia associated with chronic pulmonary tuberculosis, without the presence of fluid or air in the pleural cavities, have been reported, but in all the cases, with the exception of four, the displacement was complete when the case first came under observation.

### The Milky Way.

To boil or not to boil, that is the question:  
Whether 'tis nobler, recklessly to swallow  
The germs and toxins of raw lacteal blend,  
Or to take arms against this sea of microbes,  
And by parboiling, end them? To pasteurize—  
No more, the doctors cry, nor sterilize,  
For thus we slay the thousand healthful germs  
That milk is heir to: 'tis a consummation  
Devoutly to avoid. Thus would they lull  
Our fears to sleep. We dream; ay, there's the rub,  
For in that sleep of dreams, what rude alarms  
Awaken us! The milkman's morning call  
Disturbs our rest. There stands the milk,  
A bottled menace unto human life.  
Yet must we pay for quarts of beverage which,  
With germs benign, is mixed the contumely  
Of rural scorn for hygienic laws,  
And city dealers' dash of formalin,  
Put in to lower the count bacterial.  
Inspection does make cowards of us all;  
And thus the native hue of bovine milk  
Is sicklied o'er with the pale cast of doubt.  
From Cow to Milch Goat let us turn our thoughts,  
To Nanny, late despised, but now the queen  
Of rediscovered country, that fair realm  
Of capriculture, whence her lacteal yield  
Gives health and strength from infancy to age.

—A Caprine Soliloquy by Julia Harries Bull  
in *Good Housekeeping*.

#### Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon general, United States Public Health and Marine Hospital Service, during the week ending January 24, 1908.

Place.	Date.	Cases.	Deaths.
Alabama—Mobile	Jan. 4-11	1	0
Alabama—Mobile	Jan. 1-14	10	10
California—Oakland	Dec. 1-14	9	24
California—Los Angeles	Dec. 28 Jan. 1	1	0
Connecticut—New Britain	Dec. 1-30	1	0
Delaware—Georgetown	Jan. 1	1	0
Illinois—Evanston	Jan. 1	1	0
Indiana—Indianapolis	Jan. 4-11	1	0
Iowa—Des Moines	Jan. 1	1	0

Indiana—Lafayette	Jan. 0-13	1	0
Kansas—Wichita	Jan. 4-11	12	6
Louisiana—New Orleans	Jan. 4-11	6	6
Michigan—Grand Rapids	Jan. 4-11	1	0
Michigan—Saginaw	Dec. 29-Jan. 11	23	0
Missouri—St. Louis	Jan. 4-11	3	0
New York—Niagara Falls	Jan. 4-11	1	0
New York—New York	Jan. 4-11	2	0
North Carolina—Greensboro	Jan. 4-11	0	0
Ohio—Cincinnati	Dec. 27-Jan. 10	7	0
Ohio—Dayton	Jan. 4-11	3	0
South Dakota—Sioux Falls	Jan. 3-10	19	0
Tennessee—Knoxville	Dec. 28-Jan. 11	14	0
Tennessee—Nashville	Jan. 4-11	9	0
Texas—Houston	Jan. 1-11	3	0
Texas—San Antonio	Jan. 4-11	2	0
Utah—Cannonville	Dec. 1-3	18	1
Washington—Spokane	Dec. 28-Jan. 11	1	0
Wisconsin—La Crosse	Jan. 4-11	2	0
Wisconsin—Milwaukee	Dec. 21-Jan. 11	4	0

#### Smallpox—Foreign.

Brazil—Para	Dec. 21-28	10	4
Brazil—Rio de Janeiro	Dec. 8-15	33	9
China—Hongkong	Nov. 10-23	1	1
China—Shanghai	Dec. 7-15	2	0
17 deaths among Europeans and cases among Europeans and 2 deaths among natives.			
Ecuador—Guayaquil	Dec. 15-21	2	2
France—Marseilles	Dec. 1-31	9	9
Great Britain—Leith	Dec. 22-28	1	5
India—Bombay	Dec. 10-17	2	0
India—Calcutta	Nov. 30-Dec. 17	3	3

Minch	Dec. 17-23	1	1
India—Bombay	Dec. 10-17	11	0
India—Calcutta	Nov. 23-Dec. 7	10	0
India—Rangoon	Nov. 28-Dec. 7	1	0

Turkey in Europe—Kavak.  
Plague erroneously reported as present on December 26.  
Cases and deaths in Turkey have been included under smallpox.

#### Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the week ending January 25, 1908.

BELL, J. M., Pharmacist. Leave of absence granted for eight days from January 1, 1908, amended to read six days.  
BROOKS, S. O., Surgeon. Granted leave of absence for fourteen days on account of sickness, from January 22, 1908.  
COFER, L. E., Passed Assistant Surgeon. Relieved from duty at Seattle, Wash., and directed to proceed to Honolulu, Hawaii, assuming the duties of chief quarantine officer at that port.  
DE VALIN, H., Assistant Surgeon. Leave of absence granted for thirty days from December 16, 1907, amended to read twenty-nine days only.  
FOGARTY, J. N., Acting Assistant Surgeon. Granted leave of absence for thirty days from January 15, 1908.  
GLOVER, M. W., Passed Assistant Surgeon. Relieved from special temporary duty at Seattle, Wash., and directed to assume charge of the Service at that port.  
KEATLEY, H. W., Acting Assistant Surgeon. Granted leave of absence for one day, under paragraph 210, Service Regulations.

LAVINDER, C. H., Passed Assistant Surgeon. Leave of absence granted for one month from January 12th, amended so as to be effective January 14, 1908.

MCBRIDE, C. R., Pharmacist. Granted leave of absence for eighteen days from January 14, 1908.

TROXLER, R. F., Pharmacist. Directed to proceed to Norfolk, Va., for special temporary duty at the grounds of the Jamestown Tercentennial Exposition; granted leave of absence for seven days, effective upon completion of special duty at Norfolk.

WHITE, M. J., Passed Assistant Surgeon. Relieved from duty at Seattle, Wash., and directed to proceed to Detroit, Mich., reporting to the medical officer in command for duty.

#### Board Convened.

A board of medical officers was convened to meet in Baltimore, Md., 10 o'clock a. m., January 20, 1908, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board: Passed Assistant Surgeon J. T. Burkhalter, chairman, and Acting Assistant Surgeon J. LaB. Ward, recorder.

### Army Intelligence:

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending January 18, 1908:*

EBERT, R. G., Major and Surgeon. Relieved from duty at the Philippines Division, and will proceed on the transport to sail from Manila about March 15, 1908, to San Francisco, Cal., and upon arrival report by telegraph to the Adjutant General of the Army for further orders.

HARRIS, J. R., Captain and Assistant Surgeon. Ordered to proceed to the Army General Hospital, Presidio of San Francisco, Cal., for observation and treatment.

JONES, H. W., First Lieutenant and Assistant Surgeon. Relieved from duty at the Philippines Division, and assigned to duty in the Army Transport Service.

PALMER, F. W., First Lieutenant and Assistant Surgeon. Granted ten days' leave of absence.

RICHARDS, R. L., Captain and Assistant Surgeon. Advanced to the rank of captain.

### Navy Intelligence:

*Official list of changes in the medical corps of the United States Navy for the week ending January 25, 1908:*

ALLEN, A. H., Assistant Surgeon. Detached from duty with the marine detachment at Lajas, Cuba, and ordered to duty with the Cape Cruz-Casilda survey expedition, with headquarters at Manzanillo, Cuba.

FITTS, H. B., Surgeon. Ordered to the naval recruiting station, Indianapolis, Ind.

IDEN, J. H., Passed Assistant Surgeon. Detached from duty in connection with the Cape Cruz-Casilda survey expedition, with headquarters at Manzanillo, Cuba, and ordered to continue other duties.

MACKENZIE, E. G., Assistant Surgeon. Appointed an assistant surgeon from December 28, 1907.

RIGGS, R. E., Passed Assistant Surgeon. Detached from the Naval Academy and ordered to the naval station, Charleston, S. C., for temporary duty, and thence to Camp Columbia, Havana, Cuba.

SCHMIDT, L. M., Assistant Surgeon. Appointed an assistant surgeon from December 28, 1907.

STRINE, H. F., Passed Assistant Surgeon. Detached from the naval hospital, Annapolis, Md., and ordered to Washington, D. C., January 20th, for temporary duty, and thence to the *Relief*.

WELLS, H., Medical Director. Ordered to duty at the naval recruiting station, New York, N. Y.

WHEELER, L. H., Assistant Surgeon. Detached from the navy recruiting station, Indianapolis, Ind., and ordered to Washington, D. C., January 27th, for examination for promotion, and then to await orders.

#### Married.

BIGGS—NORRIS.—In Rutherfordton, North Carolina, on Monday, January 27th, Dr. Montgomery W. Biggs and Miss Mary Pepper Norris.

CONLEY—HINCH.—In Wilmette, Illinois, on Wednesday, January 15th, Dr. B. Conley and Dr. Minnie Agnes Hinch.

LEDDETER—COWIE.—In Annapolis, Maryland, on Wednesday, January 22d, Dr. Robert E. Ledbetter, United States Navy, and Miss Ethel Cowie.

PERCIVAL—MCBURNIE.—In Philadelphia, on Tuesday, January 21st, Dr. Milton F. Percival and Miss Mary Beattie McBurnie.

POTTER—SARGENT.—In Brookline, Massachusetts, on Saturday, January 25th, Dr. Nathaniel Bowditch Potter, of New York, and Miss Mary Sargent.

REISMAN—FLEISHER.—In Philadelphia, on Monday, January 20th, Dr. David Reisman and Miss Eleanor L. Fleisher.

RUSSELL—FOX.—In New York, on Wednesday, January 22d, Mr. Henry R. Russell, of Pittsfield, Massachusetts, and Miss Adaline Fox, daughter of Dr. George H. Fox.

#### Died.

BLAKEMAN.—In Portsmouth, Virginia, on Wednesday, January 22d, Dr. Robert Silvester Blakeman, United States Navy, retired, aged thirty-five years.

BURRALL.—In White Plains, New York, on Tuesday, January 21st, Dr. Frederick Augustus Burrall, aged seventy-four years.

BRUNNER.—In Boyertown, Pennsylvania, on Tuesday, January 14th, Dr. F. R. Brunner, aged sixty-eight years.

CAMP.—In Washington, D. C., on Monday, January 20th, Dr. Herbert M. Camp, aged forty-six years.

COLLINS.—In Covington, Kentucky, on Friday, January 17th, Dr. J. D. Collins, aged eighty-four years.

DALE.—In Lemont, Pennsylvania, on Tuesday, January 14th, Dr. J. Y. Dale, aged sixty-six years.

DANN.—In Titusville, New York, on Tuesday, January 14th, Dr. James L. Dann.

EVERSFIELD.—In College Park, Maryland, on Monday, January 20th, Dr. William Octavius Eversfield, aged sixty-seven years.

HAYES.—In Carrollton, Illinois, on Thursday, January 16th, Dr. J. B. Hayes, aged sixty-three years.

HEGER.—In New York, on Saturday, January 25th, Dr. Anthony Heger, Brigadier General, retired, United States Army, aged seventy-nine years.

KELLY.—In Philadelphia, on Monday, January 20th, Dr. Patrick M. Kelly, aged seventy-four years.

KLOCK.—In St. Johnsville, New York, on Friday, January 17th, Dr. Charles M. Klock, aged fifty years.

KNIPE.—In Boyertown, Pennsylvania, on Tuesday, January 14th, Dr. Irwin Knipe.

LOTER.—In Philadelphia, on Sunday, January 19th, Dr. Percival E. Loder, aged fifty-four years.

MCKITTRICK.—In Evergreen, Alabama, on Sunday, January 19th, Dr. A. A. McKittrick.

MATHEWSON.—In Hartford, Connecticut, on Sunday, January 19th, Mrs. Harriet Silliman Mathewson, wife of Dr. Arthur Mathewson, of Brooklyn.

MAURER.—In Philadelphia, on Friday, January 17th, Dr. Emil Maurer, aged forty-two years.

MAYER.—In Boyertown, Pennsylvania, on Tuesday, January 14th, Dr. Charles Mayer, aged fifty years.

MICHAEL.—In Binghamton, New York, on Wednesday, January 22d, Dr. F. M. Michael.

ORDRONAUX.—In Glen Head, Long Island, on Monday, January 20th, Dr. John Ordrónaux, aged seventy years.

PAINTER.—In West Haven, Connecticut, on Thursday, January 16th, Dr. Henry Wheeler Painter, aged seventy-six years.

ROSS.—In Hearshville, Virginia, on Monday, January 20th, Dr. C. A. Ross, aged forty-seven years.

SCOTT.—In Campbellsville, Kentucky, on Thursday, January 16th, Dr. Ben Scott.

SMITH.—In New York, on Monday, January 20th, Dr. A. P. Smith.

STRATFORD.—In New York, on Friday, January 24th, Dr. William Stratford, aged sixty-three years.

TURNER.—In Boyertown, Pennsylvania, on Tuesday, January 14th, Dr. F. B. Turner.

#### THE HAND AS A THERAPEUTIC AGENT.

*Calling the Attention of Physicians to Useful Auxiliary Measures Which They May Themselves Employ with Great Advantage by Adaptations of Manual Therapy, Nerve Pressures, Massage, Passive Movements, "Chiropraxis," Etc.*

By J. MADISON TAYLOR, A. B., M. D.,  
Philadelphia.

The hand is an ever present agent of skill for the physician. It is capable of infinite adaptation. Employed in a variety of directions by specialists, it is known to be the chief factor in their personal efficiency. Among primitive peoples manipulations have always afforded more certain help than crude attempts at chemical corrections. In the rude surgery of the ancients, and now in many semicivilized countries, dextrous practitioners often perform feats well worthy of imitation. In modern medicine evidence is growing to prove that we should develop and utilize these hints, always in the light of advancing physiological and clinical knowledge. While the subject is still in its infancy, the stage of conjecture, of early experiment, is past. If half as much scientific research had been expended on the principles governing manual treatment as upon pharmacology, the hand would be esteemed to-day on a par with drugs in acceptability and power.

No single therapeutic agent can be compared in efficiency with this familiar but perfect tool. Sir Charles Bell wrote a book in 1833 on *The Hand, its Mechanism and Vital Endowments*, etc., calling attention to its marvelous adaptabilities. It is pre-eminently the instrument of the artist in all departments. Swedish physicians, instigated by a prophetic enthusiast, Ling, have evolved an elaborate system of treatment, demonstrating that often by clumsy, empirical methods great things are, and greater can be, thereby done. The subject has developed slowly, but steadily, in the manner common to other lines of clinical growth. Along with aggregations of incontrovertible facts, there are being gradually evolved scientific, physiological, as well as rational, explanations. As was inevitable, such an easily imitated measure fell early into the possession of independent handcraftsmen. Many of these, while more or less competent, protected themselves instinctively and naturally by secrecy. Methods were propagated by tradition. The "bonesetters" of Devonshire, after obtruding their successes upon the puzzled and disturbed surgeons of England,

gradually contributed much to the science of surgery. Wharton Hood tells the story with valuable personal contributions in a suggestive little book on *Bone Setting*.

Few educated physicians themselves employ the hand in everyday treatments. Those who do are viewed askance. At least, they are denominated "cranks." Yet an array of their names makes creditable showing. In the preface of Kleen's book on *Massage* are mentioned a large number of well known authorities who themselves use what is called "massage and systematic movements," many of them distinguished in various recognized lines of science. Metzger to-day is overworked ministering with amazing success to the crowned and coroneted heads of Europe, and not a few "bo-nanza kings" of America.

To be sure, the utterances of many apostles of manual treatment are marred by overstatements; assertions of exclusive efficacy are often made for their personal methods beyond the verge of truth. These vaporings become distasteful to a large proportion of the profession, who, knowing little about the facts, comfort themselves with sneers or denials. If, however, the truth is demonstrable in abundance, even unguessed in its scope, it matters nothing till, in the fullness of time, all deserving things shall be made plain. So great is the potency of this measure that in recent years a vigorous cult is working, in most communities, cures, or satisfactory ameliorations of conditions, which the "regular profession" have been unable to relieve. Yet all this potentiality is entirely within the reach of these learned gentlemen if they will open their eyes and put forth their own hands.

Of course, they will come to make use of it in due time. Scientific medicine has frequently been enriched by the adoption, somewhat late, of agencies intrinsically good, but, unfortunately, discounted. Fashion, convention, ultraconservatism, is responsible for much delay in adopting many advantageous measures. It was both amusing and pathetic to observe how ludicrously reluctant many physicians, on whom or their families I have worked "unbelievable miracles," were to accept the facts. The common demurrer is to the effect that the whole thing is "mere suggestion." But why did not earlier suggestions compass similar results? What about the salutary effects wrought thus upon infants? Why does the alleged suggestion work against the avowed skepticism of these physicians themselves? Undoubtedly my own knowledge is yet too small to touch many foliages, and too much of strictly accurate correlations. The word

ologists must do a lot of better work before exact interpretations of this, or many other functional influences, are fully explainable. Facts, based upon the clearest physiological principles, are, however, abundantly in evidence. A respectable array of clinical findings are on record to substantiate all reasonable statements. Many of these are not yet marshaled in such shape as to corroborate the postulate that by touch of hand, alternating or continued, or by distributed pressures, certain curative results are wrought, though obtainable in no other way. Yet, rightly interpreted, they contribute unerringly to prove our assertions. Many of the effects produced by heat, cold, faradism, galvanism, poultices, counter irritants, section, constriction hyperæmia, deep injections of salt solutions, alcohol, drugs, and the like, are equaled or surpassed by the cunningly applied hand and through exactly the same fundamental physiological principles.

*Drug Nihilisms.*—The reaction among clinicians against the use of multitudinous drugs is reflected with exaggerations upon the laity. Injudicious condemnation by physicians of medicaments works more harm to scientific medicine than many concrete evidences of failure to afford relief. The public notices our perplexities and interprets our candid expressions of conservatism to signify doubts as to the efficacy of these unimpeachable agencies. There is a deplorable lack of consistency in medical teaching, especially in therapeutics. The cause of this is due largely to unfortunate customs in teachings, to fanciful explanation, but, above all, to faulty habits of presenting well attested truths. Drugs, used with a full knowledge of those principles which are, or are becoming firmly established, will always stand first among our keenest weapons of defense against the havoc of disease. Our literature would, unfortunately, lead a casual or overcritical reader to infer that in methods of treatment we are swayed by whims, fashions, waves of opinion, stupid imitation, or even by emotion. Hence the public, aware of our candid selfquestionings, interprets all this to signify doubts as to our capabilities. Thereupon they too readily welcome blatant, ill trained, assertive irregulars who assume to work miracles by "drugless methods." The crucial fact is that to get best results one must be aware of all important truths, by which alone exact knowledge of conditions can be attained.

As physiology slowly illumines our pathogenesis we may form more exact conclusions on the underlying potentialities which govern clinical results. Scientific medicine has repeatedly been compelled to recognize hints from irregulars which, if useful enough for adoption, may, when candidly scrutinized, be accepted without prejudice, often with great advantage to our patients. Manipulations have been increasingly employed by surgeons without criticism, but when a general practitioner undertakes similar methods he is met with condemnation. Why? Originally, i. e., previous to about 1880, whatever manipulation (massage, educative and corrective exercises, etc.) was deemed advisable was relegated to handicraftsmen or women. A certain few of these were (there always are some) both skillful and wise. Physicians then, as now, knew personally almost nothing of these measures

except a few vague and fluctuating "rules." They were, and are, even more ignorant of what should be expected of "massage" than they are now of the essential effects of drugs, and no analogue more emphatic can be cited. Even to-day few physicians make use of massage except vicariously and inexactly.

*Ignorance of Physicians on the Subject of Manual Treatments.*—In an unclear way the physician knows that through this agency certain general effects are usually induced. He has almost never had personal instruction; he would be puzzled to distinguish good work from bad, even if accurately displayed. A case comes to his mind, e. g., which he infers might be bettered by this additional measure. He thereupon selects some one on his list whom he thinks suitable, and sends him, or her, to the patient. What instruction is given? Practically none, except perhaps some negative directions learned from books as to the "contraindications." Thereupon the operator has one of two courses open: 1. To apply for specific instructions to the physician. This is seldom done. If these are sought they prove so obviously nonhelpful that the second course is open (and the one that is most generally pursued): 2. To go ahead and do whatever seems proper, giving usually an hour of routine "rubbing."

So important is intelligent, judiciously applied massage, passive movements, stretching, torsions, etc., that the laity recognize its utility more clearly than the profession. Furthermore, irregular practitioners have sprung up, forming a bold, aggressive body, adopting the best methods taught in Europe, shrewdly recognizing and utilizing the cruder points of vasomotor action and reaction whereby vasotonus is influenced, and the public is quick to see and endorse the excellent results obtained.<sup>1</sup>

It is well to emphasize the fact that all measures which influence so powerfully the functions of the human body should be kept within the jurisdiction of the educated physician. He it is who must direct and control all remedial measures. He must keep himself informed as to the principles and technique, so that he shall be able to use or direct the precise kind, direction, and amount of auxiliary measures exactly as he regulates his dosage of drugs. He must be an expert in the whole field of theories, practice, scope, and applicabilities, or else he should not use or countenance measures of which he is ignorant. If these, or other agencies, are powerfully influential for good, they are equally powerful for harm if injudiciously applied; precisely as in the misuse of drugs. It is quite true, as many will reply, that few instances of harm are brought to light. That is because expert masseurs are warned not to do those things which can work much havoc. When paid for their work they are often content to do little good, and we should be happy if they do no harm. Routine massage is, however, of only moderate efficacy. By it some surface stimulation is afforded, comfort is given, sleep and rest enhanced, slight nutritive and sensory quickenings awakened. By the passive movements ordinarily employed much good is effected in disused or chronically diseased joints. The whole cus-

<sup>1</sup> See article by the author, *New York Medical Journal*, December 11, 1914.

tomy procedure constitutes what Weir Mitchell has classically described as "the equivalent of a five mile walk without strain upon the heart."

But all these things are as child's play to the powerful effects capable of being wrought on the vasomotor and visceromotor mechanisms if the centres in the cord, the subsidiary centres, the exposed points in nerves and ganglia are intelligently operated upon by an educated physician. Here a knowledge of these governing mechanisms is required along with familiarity with the natural history and phenomena of disease, such as is assumed to be the possession of the expert clinician.

In trying to teach physicians what I myself know of the niceties of manipulations, I have been surprised to find so few, even of "distinguished clinical teachers," who are possessed of fair motor intelligence. After the plastic age is passed full manual dexterity is not attainable. Delicacy of touch is far rarer among physicians than one might assume. What they cannot perceive through clumsy, ill trained fingers they are inclined to deny. In percussion and palpation many of our "teachers" display surprising coarseness of touch. What a person of nice tactile sense may perceive instinctively, e. g., the outline of the liver, the spleen, the position and resistance of the kidneys, the stomach, varying resistance in tissues, etc., others can only infer inaccurately by awkward fumbings and gropings.

If space permitted it would be useful to set forth the significance of those variants in tissue resistance, local infiltrations, tensions, minor alterations in shape and density, in sensitiveness, tenderness, etc., especially in the erector spinæ muscles, which offer useful corroborative keys to the visceral conditions. We can thereby valuably supplement both our customary diagnostic as well as therapeutic measures.

*Aids to Diagnosis.*—It is my conviction that refinements in the education of touch, the perceptive hand, will form an essential part of clinical diagnosis as well as therapeutic teaching in the future. The laboratory, at its best, is not alone adequate to reveal many pathological indications. By habitually handling tissues much light is thrown upon many factors in diagnosis. The careful clinician thus not seldom can learn facts which would have been obvious to former advisers had they approached the problem in the same way. But sight and surface touch is a small matter compared to deeper handling, compression, palpation, estimation of resistances, of mobility or waxy compressibility.

*Aids to Therapeutics.*—The educated hand can become an exceedingly important instrument in therapeutics. While at best only auxiliary to other agents, by its use some morbid states can be more promptly and others more completely removed than by other known means. In conjunction with indici-  
ously applied hygienic measures, or clearly indicated drugs, or both, the accomplishment of complete cures in certain conditions can only thus be made certain. Any physician of moderate deftness can acquire enough skill to greatly enhance his own usefulness. A few can attain rare and many have

that supremacy of artistic capacity which makes them welcomed or famous. Variation in result here is precisely analogous to that in other handicraftsmanships. A good equipment in hand skill, along with brains and education, lifts the few above the many moderately competent. There is no more warranty in denying extraordinary results attained by manual therapy than in legerdemain, in painting, in sculpture, in violin or piano playing. Herein feeling, instinctive apperception, must supplement knowledge.

Conformation also cannot be ignored. Hands vary; some are well, others are ill adapted to the work. Motor intelligence does not always stand on a par with intellectual gifts. "Each man at arms naturally prefers to employ those weapons best fitted to his hand," be they drugs, hygiene, electricity, or manual dexterity. To omit any one may be to fail to do our full duty to the patient. The history of modern medicine exhibits manifold instances of the truth of the assertion, though relatively few failures are candidly recorded. Observant folk, however, often detect the instances of failures due to omissions. Hence when varied measures, not manual, have failed to relieve or cure; whenever a skilful craftsman presents and does achieve desired results (especially where the physician omitted to advise and direct the agent) confidence in him is shaken, the potential of the profession is lowered. This need not be; should not be permitted. The remedy is for all physicians to themselves acquire much knowledge, and at least some skill, in manual therapy.

*Massage.*—In so condensed a presentation it is only permissible to describe briefly massage as employed to-day. For sixteen years I lectured on the principles of massage at the Orthopædic Hospital of Philadelphia, and am familiar with many extensive and excellent treatises on the subject. To these the reader is referred for details of how it should be performed. Suffice it to say that wide differences of opinion obtain as to the value of general massage. Those who deny its utility, it is safe to say, are not familiar with its actual clinical effects or procedures, hence incapable of estimating the quality of the product. If a physician, however learned in other departments, prescribes a series of powerful remedies of which he knows practically nothing, but leaves the dosage, etc., entirely to the dispensing chemist, he cannot expect definite effects. This is preeminently the situation of most who prescribe massage.

There is one way, and only one, whereby one can learn what an individual can do and how to do the work; that is by submitting one's own person, or part, to be operated upon. It is next in importance to watch the operation upon a patient and estimate its immediate as well as remote effects.

The points which the critic should bear in mind are many, but among the chief of these are: 1. The rate of movements; of paramount importance are deliberation, nicety of rhythm, and confident gentleness; overrapidity is usually disturbing. 2. Depth and graduation of pressure, this should be nicely adjusted, and increased to the degree and amount required. 3. Quality of skin touch; whether dragging on the surface, pulling on superficial structures, haphazard, or what is correct

The most skillful hands, however, are not necessarily the best. Robert H. Hubbard, of Chicago, who is certainly the best, tells me that he has seen the late Dr. J. M. Little, who was a very good physician, but whose skill

firmly holding the surface tissues, seizing in turn layer after layer, with increasing grasp, while proceeding deeper, as the séance progresses, using the upper tissues to influence those underneath, till the lowermost are reached. 4. The length of time consumed. The customary full hour is often too much; an adept can do all that is needed in forty to fifty minutes, often less; more is fatiguing, often exhausting to frail persons. Subjects who "enjoy all they can get" are welcome to it; nevertheless, even then it may readily induce hurtful byeffects. 5. The kind and degree of exposure of the parts has much to do with the results. Each part should be covered immediately after treatment with a warm fabric, usually a blanket. Some persons suffer violent vasomotor reaction after massage, become chilled, or sweat profusely, or experience an extreme prostration. 6. General massage is exhausting to many invalids, especially to convalescents from infection, or to especially fragile persons, and in proportion as subjective overtension is maintained. It is an evidence of capacity in an operator, more often instinctive than acquired, to induce and maintain complete relaxation in the tissues of the subject.

It is not to be expected that a physician will himself wish to apply general massage or only occasionally. It is more likely that he will have occasion to apply localized pressures, as for sensory disorders, or *passive movements* of limbs, stretchings, and overstretchings, rotations, torsions, etc., which consume only a few minutes, demand little exertion and induce little fatigue.

These procedures are, to my mind, of almost equal utility with general massage, often of much greater. As a part of special forms of treatment, which an educated physician is best fitted to apply, e. g., for occupation neuroses, "writer's cramp," or the painful states in joints variously caused and diversely labelled, or to overcome byeffects of traumata, the milder forms of neuritis, sciatica, deepseated backaches, etc., these pressures, or passive, adjusting, elasticizing movements are of the utmost value.

*Hints as to How Passive Movements Should Be Performed.*—A few words as to how these should be given are justified. The patient should become completely relaxed; well directed suggestion will initiate this. Take up each limb, move it gently about in its normal excursus, bend and turn, then *drop it*, repeating until it falls readily with its full weight, unhindered by any conscious or unconscious tension. So of the head and neck. Next pull gradually on the limbs in turn till each is brought out to the full relaxable limit, as of the shoulder or hip tissues. Next, holding firmly the shoulder structures with one hand, or those of the hips, supporting and moulding these, haul away on the limb in its continuity, moving it through its normal excursus, one position after another, until it be made to describe passively all the attitudes it can naturally be made to assume. After this is done the limb may be (if desired to overcome contractures, or to stretch the nerves) forced with advantage a little beyond its customary positions till a slight discomfort, or perhaps moderate pain, is induced, held for three or four seconds, and carried back to a comfortable position. Gentle twistings

(torsions) should be also used, often two or three leverage actions. Finally deep, "distributed pressures" should be made on the tender point "to scatter the lymph" and the pain.

These devices are exceedingly valuable for a large variety of reasons, which could be adduced did space permit.

The mobility of the vertebral column should often come in for education, too. So also of the thorax.

To induce full mobility of the backbone it is well to cause the patient to sit on the bed, examining table, or even the floor. The physician may force the body forward and down, hands on the shoulders, or the head, or by exercising traction on the arms, to any degree desired. A number of ailments manifested by rigidities, or parasthesias, in the back can thus be removed. I have cured people of distressing backaches, suffered from for many years, by this treatment. There was often also an acquired scoliosis from traumata, and this, too, can be thus corrected. Sciatics, especially old ones, can often be permanently relieved by this means.

While it would carry one too far afield to relate at length the kinds and qualities of relief the physician can himself afford, through the laying on of hands, it may be permitted to offer a few final comments. Possessing myself rather more manual dexterity than common, this tempted me to become interested in the possibilities of hand treatments years before the public were oversupplied with "specialists" professing to "accomplish wonderful results." Accident led me to profit by the teaching of an excellent Swedish masseur named Rubesam. Much literature is available, and, if judiciously culled, full of rewards. Working some years in the physiological laboratory trained me to *look to the basic sources of both normal and morbid human activities* in interpreting the natural history and phenomena of disease. By this means I acquired the habit of *associating effects with fundamental causes*, and of looking as deeply as possible for primary principles of therapeutics. It was early found that a variety of painful states were amenable to treatment by simple, yet purposeful, manipulations. Vasoconstriction and vasodilation can be readily thereby influenced, waste products hurried into the eliminating channels, not so much by direct squeezing (massage) as by reflex stimulation through the central vasomotor substations in the cord.

So many desired effects are attainable by such simple acts that it is strange the profession has neglected to observe and make use of the vasomotor reflexes more constantly. The body is like a piano or harp, to be played upon at will. All that is needed is to work out the principles on a practical physiologic basis. I have learned from all sources, and most from John P. Arnold, who for seven years was demonstrator of physiology in the University of Pennsylvania. For example, he showed me how to promptly cure my daughter of a lameness which had resisted the efforts of the best surgeons.

The sphere of applicability of manual treatment grows larger all the time; nevertheless, I hope I am equally cognizant of the limitations.

For a long time my colleagues and personal friends adjured me to hold my peace about my convictions. I, however, hold and express such defi-

nite opinions on the indispensability of drugs that my sanity suffers no serious challenge.<sup>2</sup>

By a five or ten minutes' use of my hands I am often able to so supplement other remedial agents as to relieve, often permanently and in a vastly shorter space of time than formerly, a large variety of ailments, sufferings, and diseased states, so that I feel impelled to urge attention to these valuable measures upon all practising physicians.

1504 PINE STREET.

# IS STERILIZED MILK A SAFE FOOD FOR INFANTS?\*

BY E. MATHER SILL, M. D.,  
New York.

This question I shall endeavor to answer in the following paper largely from my own experience, but substantiated and emphasized by the experience of others.

Some six years ago my attention was drawn to this subject from the fact that such a high percentage of infants fed on sterilized or pasteurized milk were found to be diseased or abnormal. Investigations have been closely followed up from that time to the present.

We are all agreed that upon the proper feeding of the infants of to-day depends the health of the succeeding generation and the general physical condition of the nation, for the infant of yesterday is the child of to-day and the man of to-morrow, and it lies in a large measure with the profession whether the infants of to-day and of the coming generations shall be a strong, sturdy, well developed lot, prepared to resist disease, and physically equipped for the hardships they will encounter in the world, or an ill nourished, poorly developed, undersized, inferior race with little power to resist disease. In short, it is our supreme duty to find out what is for their good and our supreme business not to be defeated in realizing that good.

Before going farther it would be well to define just what is meant by sterilized, pasteurized, and raw milk, as I shall make use of these terms constantly.

To become sterilized, milk is boiled or heated to a temperature of 212° F., which temperature is maintained half an hour.

To become pasteurized, milk is raised and kept at a temperature of 160° F. to 170° F. for twenty to thirty minutes.

By raw milk we mean milk just as it has come from the cow, unheated.

Observations show that the heating of milk only moderately alters the constitution of its ingredients by disintegrating the organic union of the proteids and mineral salts. In this disintegrated state the nutritive quality and digestibility of the milk are impaired. Hence starvation and atrophy of the tissues and consequent diminution of cell growth.

If pasteurized milk is a perfectly safe food it would be universally adopted, but, besides changing the chemical ingredients and composition of the milk, it destroys the harmless bacteria, many of

which kill off the harmful kind, and thus the milk is a better culture medium for the virulent or disease breeding varieties.

We are consuming bacteria in other foods constantly. They are necessary to make our cheese, in the form of yeast to raise our bread. They are found in large quantities in the cream which makes our butter, and in numerous other substances, and in fact are necessary for the production of certain of our daily foods. So that the idea of having everything sterile before eating is wrong, impossible, and unhealthy.

Dr. Freudenreich tells us that fresh raw milk has germicidal properties, and, according to his experiments, the bacillus of cholera dies in an hour when put into fresh cows' milk, the bacillus of typhoid fever in twenty-four hours, while other germs die at the end of varying periods, and milk that has been exposed to a temperature of 131° F. loses these germicidal properties.

Russell and also Freeman, after various experiments, conclude that a temperature of 140° F. (60° C.) for twenty to thirty minutes is sufficient to destroy the bacillus of tuberculosis, diphtheria, and typhoid fever.

Recent observations by Spolverini and Hippus have proved the presence of various ferments, both in mother's milk and cows' milk, and the weakening of these ferments by a moderate amount of heat (145° F.) and their destruction by a slightly higher degree. According to Spolverini, in sterilizing milk the following changes take place in the composition of the milk:

1. Expulsion of carbonic acid gas of milk, which stimulates the secretion of the gastric juice.
2. Diminution of the amount of lime and free phosphoric acid, increase of insoluble calcium phosphate, which is not absorbed, and precipitation of the antiscorbutic citric acid.
3. A large part of the lecithin in the nucleon is destroyed and precipitated as unabsorbable, inorganic compounds.
4. The casein is changed and rendered unabsorbable, and the soluble albumin is coagulated.
5. The fat globules unite into larger masses, that are less easily absorbable.
6. The ferments are destroyed, and thus are lost antitoxic and immunizing substances, and microbicidal compounds of great value to the child. These disadvantages result in the child being pale, with soft flesh, having a predisposition to intercurrent diseases and a lack of resistance to ailments, with rickets, showing disturbances of nutrition.

It has been stated that the germs of typhoid fever, diphtheria, scarlet fever, and consumption are frequently carried by milk. No doubt this is true in a few instances, but we all are familiar with the latest method of treating consumptives by giving several quarts of raw milk each day, and for years patients with the other diseases mentioned above have been fed on raw milk.

If we subject fresh milk that contains germs to heat, the milk still contains the dead germs and their toxins. Heat does not purify milk by killing the germs, and the toxins contained will cause disease.

What, then, is meant by a "safe" food? A safe

\*See the *Eastern Journal of Medicine*, November, 1906, p. 1000.

<sup>2</sup>Read before the meeting of the American Association of the Study of Diseases of the Digestive Tract, held at New York, Sept. 28, 1908.

food for an infant is one in which all the elements of the milk have been unchanged as to their organic union. Heating disorganizes these elements, devitalizing the milk and changing it from a *live*, fresh food to a *dead*, preserved food.

It being my privilege to have yearly under my care some 5,000 infants, I have had exceptional opportunities for studying the various methods of feeding, especially as we have our own diet kitchen for the modification, sterilization, and pasteurization of milk (nearly two hundred infants being fed daily). Careful observations have been made for a period of over five years on all the infants, about 25,000 in number, and accurate knowledge as to the exact method of feeding was obtained.

Of those infants that were fed on sterilized or pasteurized milk continuously or part of the time on one and part of the time on the other, ninety-seven per cent. developed scurvy or rickets or a combination of the two, the so called scurvy rickets of the English authors. These infants had been fed for a varying period of from three to eighteen months on the heated milk; pasteurized milk was given during nine months of the year and sterilized milk during the three summer months. This milk was all carefully modified to suit the age and digestion of each individual infant. About 20 per cent. of the infants had five feedings a day supplemented by breast feedings. These also had signs and symptoms of rickets, but in a degree less than those who were fed exclusively on pasteurized or sterilized milk. No infants fed on *modified raw* milk developed rickets or scurvy or any other disease due to improper feeding, such as anemia, malnutrition, marasmus, etc.

According to Koplik, manifestations of rickets may show in the *bones* at autopsy when no symptoms have shown during life, but these children had been fed on foods which are known to produce rickets. I have seen great numbers of infants with the earliest symptoms of rickets, and spongy or bleeding gums of varying intensity, but with no other symptoms of infantile scurvy, and also numerous other infants with purpuric hemorrhages and slight sponginess of the gums. The majority of these infants, it was found, were fed on sterilized or pasteurized milk, and promptly responded to the use of raw milk with no other treatment. The greatest number of my cases of scurvy have been of this mild type or early stage of the disease, but which were just as much infantile scurvy as those with more pronounced symptoms of periosteal hemorrhage, pseudoparalysis, pain, fever, prostration, etc.

These conclusions based on observations at our own laboratories are substantiated by investigations which I have made on infants fed at other laboratories and at home. It has been found that every infant suffering from rickets, scurvy, malnutrition, etc., that has come to our notice and that has not been fed on any of the patent baby foods has, however, been fed for varying periods on pasteurized or sterilized milk.

It would seem, then, that there was a common cause of disease in these cases, namely the use of sterilized or pasteurized milk.

Being anxious to know whether sterilization and pasteurization of milk was the entire cause of these

diseases raw milk was substituted with no other treatment, whereupon the children immediately began to improve.

Infants which were in good health when fed raw milk, were attacked with symptoms of rickets when sterilized or pasteurized milk was given.

Those who have had a large experience working among the poor of our city, and know the gross ignorance displayed by the mothers in the feeding of their infants, fully realize the fact that the reduced mortality from diarrhoeal diseases of recent years has been due not to the fact that the milk has been sterilized or pasteurized, but to the improved method of feeding by the modification of the milk to suit the age and wants of the child and putting the milk up in stoppered nursing bottles that are kept on ice until the time of using. Also a better grade of milk has been used.

It might be interesting to note here that T. M. Price, chemist at the Maryland Agricultural Experiment Station, made a series of experiments on calves to ascertain the comparative nutritive value and digestibility of pasteurized, sterilized, and raw milk. The result of these experiments showed that:

1. More fat and proteid were digested when raw milk was given than when pasteurized milk was given.

2. More proteid and fat were digested when pasteurized than when sterilized milk was given.

3. More proteid and fat were digested when raw milk was given than when sterilized milk was given.

4. Calves gained more when raw milk was fed than when pasteurized milk was fed, and still more than when sterilized milk was fed.

5. Calves lost on sterilized milk, were stationary or gained very slowly on pasteurized milk, and gained rapidly on raw milk.

6. Diarrhoea was set up in calves by the use of sterilized milk and stopped when raw milk was fed. Since these experiments show definitely the effect of sterilization and pasteurization of milk upon young animals it is natural to conclude a similar effect upon infants. The most characteristic feature distinguishing sterilized from raw milk is the state in which the albumin exists, and Richmond says that this is changed from a soluble to a colloidal form, and not more than 1 per cent. of albumin is found in sterilized milk in a soluble form, while in raw milk over 4 per cent. is in a soluble form. The appended table from Richmond's *Dairy Chemistry* shows the percentage of soluble albumin in milk at various temperatures:

Time of heating.	Soluble Albumin in fresh milk.	Soluble Albumin in heated milk.
10 minutes 60° C.	0.423 per cent.	0.418 per cent.
30 " " "	0.438 " "	0.42 " "
10 minutes 65° C.	0.395 per cent.	0.365 per cent.
30 " " "	0.395 " "	0.363 " "
10 minutes 70° C.	0.422 per cent.	0.269 per cent.
30 " " "	0.421 " "	0.253 " "
10 minutes 75° C.	0.380 per cent.	0.07 per cent.

Koplik has shown by chemical tests that more nitrogen is assimilated by the infant from milk that has been subjected to little or no heat.

There is one apparent exception to what has been said in regard to raw milk, namely, I have seen cases of rickets develop in infants who were fed for

too prolonged a period on poor quality breast milk or poor quality and much diluted cows' milk, and here again we have the same or a similar condition prevailing that we see in the use of heated milk, namely, deficiency of proteids and salts. When these infants were given a milk of sufficient strength for their age immediate and permanent improvement was noted with a healthy, steady growth.

Then it would seem the above mentioned diseased conditions are brought about by deficiency and change of the proteid molecule and the alkaline earthy salts organically combined. This condition of unabsorbability being caused by superheat.

Landois, in speaking of rickets, says: "The normal nutrition of muscular tissue can only take place if sufficient supply of sodium chloride and potassium salts is provided in the food, as they are integral constituents of muscular tissue, otherwise the muscles atrophy and their reconstruction is prevented. In such conditions the central nervous system and the digestive apparatus also suffer, and the animals perish." This, no doubt, accounts for the frequent occurrence of convulsions in rickets.

**Conclusion.**—In closing it would seem then, after careful clinical observation of many cases substantiated by chemical research and bacteriological findings, that the conclusion to be drawn must be that the advantages of the raw milk, when properly used, far outweigh any advantages which highly heated milk may possess. And if milk is heated it should never be raised above a temperature of 140° F. for twenty to thirty minutes.

142 WEST SEVENTY-EIGHTH STREET.

#### THERAPEUTIC USE OF SOURED MILK.\*

By HAVEN EMERSON, M. D.,  
New York.

The use of soured milk is based on three distinct properties:

1. The fact that pathogenic bacteria do not thrive in a medium that has a marked degree of lactic acid.

2. The process of carbohydrate and proteid disintegration occurring in the souring of milk makes a softer and more digestible and smaller casein curd, and a carbohydrate in a state of partial digestion.

3. Lactic acid activates peptic secretion and digestion.

The use of soured milk is indicated broadly as a preventive against the putrefactive process of proteid disintegration in the digestive canal. It is useful in the feeding of infants and invalids who are suffering from disordered digestion, especially of the fermentative types. It is safer than unsoured milk where the supply is not clean enough to be above suspicion. Its use has been proved valuable in the dietary treatment of pulmonary tuberculosis and in the modified food of healthy infants.

Chemically milk may be separated into classes, as: 1, Whole milk; 2, whey, that is, whole milk minus casein and fat; 3, skimmed milk, i. e., whole milk minus fat and a small amount of casein; 4, butter-milk, really the same as skimmed milk, but usually a term applied to soured skimmed milk.

Bacteriologically milk may be separated into classes, as: 1, Clean milk, i. e., free from bacteria; 2, pasteurized milk; 3, sterilized milk; 4, putrefactive milk, i. e., milk containing putrefactive bacteria; 5, pathogenic milk, milk containing pathogenic bacteria; 6, lactic acid milk, i. e., sour milk—(a) due to the presence of lactic acid bacteria with or without the presence of yeast, free from pathogenic and putrefactive bacteria, and (b) due to the presence of lactic acid bacteria with or without yeast, but accompanied by pathogenic, putrefactive, and harmless bacteria.

If we want to use soured milk we should demand: 1, Clean, whole milk. This is a necessary prerequisite if we wish to avoid the necessity of pasteurizing or sterilizing the milk before we start the process of souring. 2, The milk should be skimmed fresh, preferably by mechanical centrifugal separation immediately after chilling, subsequent to milking or during the process of chilling. 3, If the milk is not free from pathogenic or putrefactive bacteria it must then be sterilized, to put an end to the growth of pathogenic and putrefactive bacteria, and to enable us to control the results of our subsequent inoculation without the interference of undesirable organisms. 4, The milk should then be inoculated with an exact dose of biologically standardized bacteria. Probably the inoculation with bacteria should be accompanied by inoculation with known cultures of yeasts. The yeast is necessary: 1, To inhibit the overgrowth of pathogenic and putrefactive bacteria; 2, to add flavor which cannot be obtained without it, presumably by the production of aromatic substances such as esters; 3, to attack milk sugar after lactic acid has been formed in the milk, and produce alcohol and carbonic acid gas, which are valuable assistants in the digestion and absorption of milk and in making milk tolerated by irritable and congested mucous membranes.

It is believed that yeast cannot ferment milk by itself, but needs the preparation of the milk by lactic acid bacteria before it can itself be effective. Bacteria are necessary: 1, To prepare for the action of yeast; 2, to form lactic acid to an amount of, in some instances (e. g., *Bacillus bulgaricus*), as much as 2.8 per cent. of lactic acid; and, 3, to break up the proteid.

The yeasts which ferment milk rarely, if ever, cause disease processes, and their selection depends upon the flavors, the carbon dioxide, and the alcohol which they develop, and their availability for distribution and preservation.

The bacterial flora of the feces of humans and all domestic animals normally contains lactic acid souring bacteria, and the so called natural souring of cows' milk is due in all probability to the infection of the milk with the dust from stable manure.

Most pathogenic bacteria will produce lactic acid souring in milk. Pathogenic and nonpathogenic cocci produce lactic acid souring of milk. It is apparent then that the bacteria to be used for souring purposes must be selected from among the nonpathogenic varieties, and among these preference is to be given to those which produce a large and constant amount of lactic acid. At present the demand is apparent for a distinction between pathogenic and nonpathogenic cocci appearing in cows' milk, as some

\*Read at a meeting of the Society of the American Medical Association, December 4, 1906.

are useful, but all are at present under suspicion of being pathogenic.

After lactic acid souring or fermentation has proceeded to a certain point putrefactive processes get the upper hand, if putrefying bacteria are present in the milk used for souring. Some of these bacteria ferment lactic acid and destroy the proteids in the milk; thus at the same time we have an injury to the nutritive power of the milk and a neutralization of the useful acidity, so it will appear that a milk which at one time would be valuable and safe, at a little later date would have lost much of its value and some of its safety as the result of impure inoculation or of inoculation of unclean milk.

In inhibiting the growth of harmful bacteria in the milk there is no positive proof whether the yeasts or bacteria are more efficient, the important point being, apparently, a constant and considerable production of lactic acid to hold other microorganisms in check.

The mere presence of cocci in milk or in the "starter" or bacterial dose used to sour milk need not be considered as harmful or necessarily detrimental to the usefulness or safety of the milk. The value of soured milk will depend, then, upon the purity of the original supply, the promptness and cleanliness of its subsequent handling, the constancy of the amount and quality of the dose of the "starter," or activating combination of yeast and bacteria, the limitation of the resultant fermentation at the proper point, and the subsequent care of the milk at a constant low temperature.

If we are to introduce soured milk into our households, as there is good ground for believing would be of advantage, or if we are to rely upon its use in the prevention or treatment of disease, we must not rely upon haphazard infection with undetermined amounts or kinds of yeasts or bacteria, but we must demand at least as high a standard of purity as is expected in whole milk, and as exact a control of the yeast and bacteria to be used as is maintained in the production and dosage of diphtheria antitoxine or tuberculin.

For facts which I believe to be correct as they are above presented I am indebted to Professor F. C. Wood, Dr. Hans Zinsser, and Dr. Charles E. North, who kindly answered my questions and put me right in matters in which they could speak with authority.

120 EAST SIXTY-SECOND STREET.

long suffered and continues to suffer from unfounded hypotheses which time will not permit me to specifically refute on this occasion.

Uric acid is not a product of the catabolism of proteids in general. It is a product formed by the destructive metabolism of a particular class of substances more or less closely related to proteids and usually found in combination with them; namely, those substances into the composition of which nucleic acids enter. As to what nucleic acids are, I may explain that they are organic compounds of a complex phosphoric acid containing in combination with the phosphoric acid, purin bodies and possibly other organic compounds, notably the pyrimidine and carbohydrate groups. As illustrative of their nature we have two nucleic acids which have been successfully studied and the composition of which is provisionally indicated by the following formulæ:

Triticonucleic acid has been isolated from the wheat embryo. The phosphoric acid portion is a combination of four molecules of orthophosphoric acid in which hydroxyls are replaced by: (1) Two molecules of purin bodies; (2) three molecules of the pentose sugar, l-xylose; (3) two molecules of a pyrimidine body, uracil; and (4) one molecule of an unidentified base, designated x.

In the formula the first, second, and third bodies enumerated are underlined by one, two, and three lines, respectively.

Guanylic acid is the nucleic acid obtained from the pancreas. It is made up of a phosphoric acid portion, much the same as in triticonucleic acid, with which are combined: (1) Four molecules of a purin body, and (2) three molecules of a pentose sugar united to the phosphoric acid by means of an intervening glyceryl radical. I have underlined the purin body once, the pentose twice, and the glyceryl radical three times.

Nucleic acids, differing in detail, but, so far as we know, similar in type to these illustrative examples, exist in the body almost wholly in combination with simple albuminous substances, forming the nuclein and nucleoprotein compounds that are present in all living cells, and, indeed, make up a large portion of the cell nucleus. Their interest to us at this time is that as a result of destructive cell metabolism, the nucleic acid compounds yield purin bodies which, as we have seen, enter so prominent ly into their composition.

#### URIC ACID; THE FORMATION, ELIMINATION, AND EFFECT ON THE GENERAL SYSTEM.\*

By E. E. SMITH, M. D., Ph. D.,  
New York.

Professor of Physiology and Organic and Biological Chemistry in  
Columbia University, School of Medicine.

In directing your attention to the trinity of subjects assigned to me for this evening, I ask you at the outset that during this presentation you entirely rid your minds of previous theories, in order that the views here considered may make their own impressions upon your judgments. The subject has

\*Presented at the New York and Connecticut  
Society, November 27, 1907.

The purins are closely related to uric acid, and, in fact, are transformed in the body into uric acid, itself a purin. In order to understand these changes we must consider the structure of the purins. They are all constructed on a plan most readily understood by considering their relation to the purin framework, representing the positions of the carbon and nitrogen atoms in the purin molecule:

For convenience of reference, the various positions in this framework are numbered from 1 to 9. Thus, we have the following purin bodies, which have been obtained from animal substances and whose structures are built up by substituting in the positions indicated the amino ( $\text{NH}_2$ ) group and oxygen:

The chemical changes by which these closely related purins are transformed into uric acid consist of two stages. First, the deamidizing of adenine and guanine, by which change the amino groups are replaced by oxygen, and there results, in place of the adenine and guanine, the closely related hypoxanthine and xanthine. Second, the oxidation of the hypoxanthine and xanthine, by which change these latter take on oxygen, and are directly transformed thereby into uric acid.

In order to fully appreciate the formation of uric acid in the body it is necessary not only to know the chemical transformations which we have now traced and which result in uric acid formation, but also the factors operative in producing these changes. Recent years have led biologists to the generalization that the chemical changes which constitute the activity of living cells are facilitated through the agency of those catalytic substances known as enzymes. It has been only in comparatively recent time that the name enzyme has suggested to us more than the activities of alimentation; now, there is good reason to believe that these agents are concerned in practically all the chemical changes of the body—in the constructive changes of metabolism by which the tissues are maintained and the destructive changes by which they carry on their work.

In purin catabolism five classes of enzymes may be concerned:

1. Proteolytic enzymes, which act upon the proteid compounds of nucleic acid, liberating the latter.
2. Nucleases, which facilitate the breakdown of nucleic acid with the liberation of purins. Of the importance and wide distribution in the tissues of these enzymes there can be no doubt, but specific knowledge of the nucleases is limited.
3. Amidases, which are concerned in the deamidizing of the aminopurins. These enzymes have been carefully studied. Not only is their existence known to us, but difference in action and distribution in various animals has been discovered. They have thus far been found in the spleen, liver, lung, muscle, thymus, and suprarenal; not in the intestines, blood, or kidneys.

4. Oxidases, which facilitate the oxidation of hypoxanthine into xanthine, and, subsequently, xanthine into uric acid. This enzyme is found in spleen, liver, muscle, and lung. Its action has been repeatedly demonstrated.

5. Uricolytic enzymes, found especially in the kidney and liver, and in lesser amount in muscle and bone marrow, the action of which is concerned in the processes by which uric acid, formed by the chain of chemical transformations which we have traced, is in turn destroyed—that is to say, oxidized to simpler products.

In the foregoing presentation of the purin origin of uric acid I have spoken of its derivation from the nucleic acid constituents of body cells. Uric acid from this source is designated as endogenous in contradistinction to exogenous uric acid, derived from the purins by changes entirely similar to those we have considered, but differing in origin in this particularly, namely, that instead of being derived from body cells it is formed from the purin containing constituents of the food. This is not only a possible source of uric acid formation, but a source in fact, one which under some circumstances may yield as much, or even more, than the endogenous uric acid. The distinction of endogenous and exogenous uric acid is, then, of practical as well as theoretical importance.

There remains to consider a third possible mode of formation, namely, the synthesis of uric acid. We know that in growth nucleic acid and its compounds may originate from purin free material, such an origin being, of course, necessarily synthetic. Why, then, may not uric acid be regularly formed in this way in man? The possibility becomes more plausible when we realize that such a mode of origin has been proved in birds. In man, however, no experimental proof of such origin has yet been adduced. Certain facts are explicable on the assumption of this source, but they are equally so on the basis of the purin source. In the absence of supporting evidence the view of the synthesis of uric acid in man remains an unnecessary and unsubstantiated hypothesis. We shall refer to the matter again in discussing the pathological increase of uric acid.

While, as we have seen, the chemical transformations and the dynamic factors of uric acid forma-

tion are pretty clearly appreciated, it must be acknowledged that it is not so well understood in what tissues and organs these changes occur. The wide distribution of the enzymes concerned suggests that uric acid formation is not limited to any one tissue or organ. Indeed, the interpretation of experimental observations calls for the recognition of uric acid formation as a widely distributed occurrence. Certain facts, however, render it probable that the formation of endogenous uric acid is especially abundant in muscle tissue. Thus, increased muscular activity is followed within an hour or two by an increased output of uric acid, while the perfusion of muscle with blood and Ringer's solution shows an increase of uric acid and hypoxanthin after exercise. Again, overfatigue is followed by a very considerable increase of uric acid output. It is probable, therefore, that ordinarily muscle metabolism leads to the formation of hypoxanthin, which by oxidation yields a large portion of the endogenous uric acid. We must also credit the muscles with greatest capacity to destroy the uric acid formed, the kidneys next, and then the liver, for, while muscle weight by weight is less active than the kidney and liver in the further oxidation of uric acid, whereby it is broken down into simpler products, yet the absolute quantity of the tissues in the body seems to give to muscle as a whole the greatest uricolytic capacity.

Considering the matter of the elimination of uric acid, it will be appreciated that the quantity that appears in the urine is not determined by any one circumstance, but is the resultant of the following operative factors:

1. The formation of uric acid (*a*) by endogenous purin metabolism; (*b*) by exogenous purin metabolism; (*c*) possibly in a slight measure by uric acid synthesis.
2. The destruction of uric acid by uricolytic ferments, particularly in muscle, kidney, and liver.
3. The retention of uric acid (*a*) by deposition in the tissues; (*b*) by limited excretory capacity.

In order to reach any conclusion in regard to uric acid elimination, it is necessary to know the amount excreted in twenty-four hours. This period represents the cycle of body changes. At particular hours such marked variation of the amount of uric acid excreted normally occurs as to rob such amounts of any value as indicating the uric acid elimination as a whole. If we pretend to any knowledge of uric acid excretion there is no substitute for accurate information of the quantity eliminated in twenty-four hours. The acidity of the urine is of no value as indicating a uric acid increase, since, on the one hand, uric acid is not a determining factor in the production of urinary acidity, and, on the other hand, the quantity of uric acid does not even vary directly with the acidity, but is quite as likely to vary inversely with it; in other words, the quantity of uric acid eliminated is in no way related to the urinary acidity. Equally valueless are the makeshift methods of determining the fact of uric acid increase without accurate determination of the amount present. Such procedures are indefensible—worse than valueless.

In this day of pretended scientific accuracy and popular misapprehension as to the significance of uric acid, the use of these methods certainly partakes of charlatanism. There is no emergency that demands such pretense of knowledge, and we owe it to our profession, our patients, and ourselves not to employ under the guise of science these or any other mere vagaries of the imagination.

Moreover, in our discussions of the subject and especially our presentations of facts as to cases, we should plainly indicate upon what our statements of the uric acid elimination are based, whether upon facts honestly determined or upon statements merely asserted or not completely established under the thin guise of clinical privilege. It is only by strict adherence to this principle that we can hope to establish the truth and escape the charge of fostering popular misapprehension.

But even the accurate knowledge of the amount of uric acid eliminated does not assure us of its correct interpretation. So many factors may influence the elimination as to call for the exercise of great caution regarding any conclusion as to the influence of a given factor. Considering the factors in the order enumerated, we have, first, the elimination of uric acid formed by endogenous purin metabolism. This amount is found to vary in different individuals from 0.1 to 0.3 gramme or perhaps more in twenty-four hours, but in health is fairly constant in the same individual, due, in all probability, to individual habits of life and to individual musculature. Moreover, within ordinary ranges of diet, there is no material influence of the quantity of food on the endogenous uric acid output, although with great reduction of diet the elimination is reduced.

In certain diseased conditions the production and elimination of endogenous uric acid may be increased. This is strikingly so at certain times in leucæmia, but not always. Again, we are apt to find an increased uric acid elimination, ascribable to increased endogenous formation, during the resolution of a pneumonic exudate; likewise, though inconstantly, in acute hepatic atrophy. In fact, whenever there is much destruction of the nucleoproteids of tissues, an increased elimination of endogenous uric acid is to be looked for, and, oftentimes, is found.

Variation in the amount of uric acid eliminated is due more commonly to the quantity of exogenous uric acid than to any one factor. This, as we have seen, is derived from the purins, free or in combination, contained in the ingested food. In man, about one half of these purins are eliminated as further oxidized products and one half as uric acid.

In order to allow for the fluctuation of the urinary uric acid, under the influence of the variable amount of food ingested, clinicians early employed the ratio of the uric acid to the urea as an index to the uric acid eliminated, taking advantage of the fact that the urea varies directly with the amount of nitrogenous food ingested. Thus, Herter and Smith, expressing the total nitrogen of the urine as urea, found that the uric acid urea ratio ordinarily varies in health from 1:45 to 1:65, being fairly constant in the same individual. As is expected in the

light of our present knowledge, the former figure was obtained with subjects on a purin containing diet, the latter with subjects on a purin poor diet. As we now know, the elimination of uric acid may be increased beyond this limit by the ingestion of food unusually rich in purins. The ratio, then, becomes an index to uric acid elimination only when the character of the diet is considered. The interpretation of the absolute amount of uric acid not only calls for consideration of the character of the diet, but also the exact quantity of purins contained therein. As will be appreciated, with diminishing amounts of ingested food of a given kind, since the absolute quantity of exogenous uric acid eliminated constantly diminishes while the endogenous uric acid remains constant, or nearly so, there is a relative uric acid increase, seen by an approach of the ratio to the unusual or pathological limit. This fact robs the ratio of any pathological significance when the absolute quantity of uric acid is below a certain amount. The writer empirically recognized this amount as 0.4 gramme, a figure which with our present knowledge of the cause of the limitation has remained as the lowest limit permitting any interpretation of the uric acid elimination by aid of the ratio.

Passing for the moment the possibility of uric acid formation by synthesis, we come to the consideration of the influence of uric acid destruction on its elimination. Experimental observations have entirely failed to substantiate the early view of clinicians that uric acid is a product resulting from lack of oxygen to oxidize nitrogenous products to the final, urea, stage. We now know that if the limitation of uric acid destruction causes an increased elimination, that it does so through inactivity of the uricolytic ferments and not through any deficit in the oxygen supply.

There is reason to believe that this factor is of very great importance in the production of the urinary increase of uric acid in many pathological states. This has been established with the greatest degree of probability by the results which follow the administration of large quantities of alcohol. Early experiments by the writer in Chittenden's laboratory showed that the ingestion of much alcohol decidedly increased the elimination of uric acid in dogs; later experiments by Beebe showed that this only occurred when the ingesta contained purins, suggesting that the increased elimination results from a failure of the uricolytic ferments to further oxidize exogenous uric acid formed, this failure, most likely, resulting from hepatic or renal uricolytic insufficiency from the action of the alcohol. The same explanation probably applies to the increased uric acid elimination which has been observed to follow the administration of certain other drugs, notably the salicylates which Herter and Smith and others have found to increase uric acid elimination. Moreover, it affords a reasonable explanation of the increased uric acid elimination observed in the pathological states in which digestive derangements, notably gastrointestinal toxæmias, appear. This includes many cases commonly classed as neurotic, such as neurasthenia, epilepsy, certain insanities, etc.; also many cases of so

called chronic rheumatism, arthritis; in fact, cases of any disease with a gastrointestinal disturbance and presenting a uric acid increase may find an explanation of such increase at least in part in the uricolytic failure to destroy the exogenous uric acid. It is not probable that this failure is in all instances limited to the uric acid of exogenous origin. Thus, the uric acid increase following extreme fatigue is most likely derived from diminution in the destruction of the uric acid formed in muscle and therefore may be attributed to uricolytic failure.

Before leaving the subject of diminished destruction of uric acid by failure of enzyme action, let me return to the part uric acid synthesis may play in those cases of increased elimination which we have just been considering. Peculiarly enough, these are mostly, and perhaps all, cases in which the morbid processes concerned afford products capable of yielding uric acid formation by synthesis. We are, therefore, confronted with the question whether the increased uric acid elimination is in truth due to diminished destruction by uricolytic failure or to increased uric acid formation by synthesis. In a former communication the writer expressed the opinion that the latter process contributes largely to the result. With our present knowledge of the subject, an hypothesis suggests itself that is not only consistent with known facts, but is in keeping with our knowledge of enzyme action. The last few years have revealed the fact that enzymes possess a reversible action. This was first demonstrated with the fat splitting ferments, which, while they split up fat into glycerin and fatty acids in the absence of these products or when present in limited quantity, on the other hand, when the products of the splitting action are present in sufficient amount, the ferment not only fails to exercise its fat splitting function, but actually acts in the opposite direction, combining the glycerin and fatty acid to form neutral fat. There is some probability that the uricolytic enzymes have an analogous mode of action, the relative quantity of the products of uric acid destruction, or, what may be the same thing, products of morbid processes which are capable of being built up into uric acid, determining the rate of action of the uricolytic enzyme, and, perhaps, if the quantity of such products be sufficient, actually reversing the direction of action and leading to the synthesis of uric acid instead of its destruction. If this be so, the products of morbid processes and the overproduction of lactic acid in extreme fatigue increase uric acid elimination by limiting uric acid destruction through a diminution of the action of uricolytic enzymes and possibly in extreme cases by increased uric acid formation through synthesis. The acceptance of this hypothesis does not prevent the recognition of some degree of limitation to uricolytic activity by the direct inhibitory action of drugs and toxins.

It is well established that in a limited number of diseased conditions there is an excess of uric acid in the blood and perhaps the tissues. The cause is uncertain. Diminished renal secretory capacity, excessive production, fixation in the blood and tissues,

are all to be considered as possible causes. There is no proof of diminished renal secretory capacity excepting clinical facts, which are these: First, a diminution in the uric acid eliminated at a time when there is an increase in the blood. This happens for several days before a gout attack and in some cases of nephritis. While the evidence is far from conclusive, it seems to suggest in these cases retention by limited excretory capacity. Yet the possibility of the uric acid being held in the blood in some form that cannot be eliminated must be admitted. At all events, in these cases the formation of uric acid is undesirable, because of the tendency to deposit in the tissue, on the one hand, and the demand on the kidneys to which these organs are unable to respond, on the other. It is to be emphasized, in this connection, that these cases of uric acid retention are numerically relatively inconside-  
rable. The disturbances in uric acid metabolism are in the main due to excessive formation and deficient destruction in the ways we have already discussed.

The third section of our subject, the effect upon the general system, can be briefly presented. Uric acid is possessed at most of a very slight degree of toxicity. Aside from the instances where it is deposited in the tissues, as tophi, infarcts, or as embedded crystals, and produces mechanical injury, it is not known to cause any pathological condition. It is eliminated in increased amount in many pathological states, but this is the result of processes already discussed rather than evidence of its aetiological relation to such disease conditions. But as an infarct or calculus or in the form of irritating crystals we cannot question its injurious action. As to the relation of uric acid deposits to the slight local necrosis which accompanies their deposition there is reason, though inconclusive, to attribute the necrosis to the action of the urates. The fact that joint cartilage has a special affinity for urates seems established, and it is reasonable to believe that the deposition results because of this affinity and because of the excess of uric acid in the blood. The cause of the excess may be increased formation, diminished destruction, and, probably most important, diminished elimination.

26 EAST TWENTY-NINTH STREET.

#### INTERNAL MEDICINE: SOME OF ITS PRESENT ASPECTS AND ACHIEVEMENTS.\*

By G. W. McCASKEY, M. D.,  
Fort Wayne, Ind.,

Professor of Medicine in the Medical Department of Purdue University.

The work of much less than a generation has wrought a revolution in medicine. Great discoveries, fundamental in their influence upon the practice of the healing art have followed each other in bewildering succession. The telephone, the phonograph, and wireless telegraphy are not more startling in the domain of physics than antitoxines and vaccine therapy in that of medicine. Amid this great upheaval of fact and theory many attractive questions offer themselves for consideration; ques-

tions which will continue important until practical medicine has adjusted itself to its new and ever changing environment. Instead of selecting any one particular question for discussion, I have decided to ask your attention to some aspects of the special field of internal medicine which has at least kept pace with surgery in the remarkable advances of the last two or three decades. If its conquests have been less dramatic they have been none the less real. To those whose mental vision can see things in their true perspective, disregarding for the moment the glamour of the amphitheatre and the flash of the footlights even the dramatic element is there, although the action is necessarily slow.

An internist, for instance, has to deal with a heart disabled by toxic or other causes, or a brain, or a stomach the functions of which are impaired to the point of disability, or a metabolism in which chemistry has run riot. These are fairly representative problems which he has to meet.

Now, if it were a gallstone in the common duct, or a removable neoplasm anywhere, the patient could be put on the operating table, and the real battle could be over in thirty minutes, although it might take thirty days for the smoke to clear away. But here is an organ that has perhaps suffered from slowly acting causes, which have produced nutritional changes to all intents and purposes structural in character. Associated with these changes there are almost certainly more or less widespread perversions elsewhere. Everything must be taken into account, and a definite plan of campaign marked out. The patient becomes an ally, more or less reliable, and through weeks and perhaps months of waiting the campaign moves on. The result may be, as I have repeatedly seen, and as every clinician of experience has seen, a more or less complete restoration of function, and return to health. The clinical picture before and the clinical picture after present a contrast just as striking as that of any surgical case, the difference being one of method and time. These are facts and points of view which I believe to be worth emphasizing in this connection, because of the tendency (which is fast disappearing) to belittle the methods and results of internal medicine, when, as a matter of fact, no such sentiments should exist on the part of either surgeon or internist, because each needs the help and should rejoice in the achievements and triumphs of the other.

The terms internal medicine and internist or internalist have acquired a new significance within the last few years. The many scientific discoveries and appliances which have been given a clinical application, together with the technical skill and knowledge required in dealing with the more difficult problems of diagnosis and therapeutics have placed internal medicine in the list of specialties. It is just as impossible for the general practitioner to master this field as it is for him to become an expert general surgeon or ophthalmologist. No one can esteem more highly than I do the splendid character and sterling qualities of the family adviser. It is inconceivable that his position can ever be shaken or his functions usurped. He must ever continue to be what he is now, the high priest of the domestic sanctuary across the sacred precincts of which he should pass with uncovered head and unsullied

\*Read at the meeting of the North Western Ohio Medical Association at Toledo, Ohio, December 13, 1907.

heart. He should know something of all the specialties; enough to decide whether or not his patients need the special diagnostic and therapeutical resources of any one of them. This is very generally recognized with reference to surgery, ophthalmology, laryngology, and a few others, and the time has certainly arrived when it should be recognized with reference to internal medicine.

The man who devotes himself exclusively to internal medicine has a field which will tax his abilities to the utmost, no matter of how high an order they may be. This is recognized by the leading medical men of the world. Professor Osler, for instance, in the introductory chapter to the first volume of *Modern Medicine*, says: "The profession should learn to recognize the worker in internal medicine as a man who has to devote so much time to his studies that it is impossible for him to take general practice, and in a way he is a specialist, in the broad sense of the term, like the surgeon." No general practitioner worthy of his calling would think of letting a patient die of a ruptured extrauterine gestation or lose an eye from an acute glaucoma without endeavoring to secure for the patient the best skill available. The conditions and results in such cases as these are so striking that every one, layman and physician alike, recognizes the necessity of prompt action. The limitations and obligations of the general practitioner are clearly defined and fully recognized. Now, if what I have said is correct then the limitations and obligations of the general practitioner with reference to a small percentage of cases falling within the particular domain of internal medicine in its limited sense are equally plain, and the patient, for instance, with a stomach, brain, or heart disturbance of severe and unusual type; or with an obscure nutritional or metabolic disorder is fully entitled to the privilege, if he chooses, of having such advantages as may be derived from such a comprehensive knowledge of the recent advances along these lines, as is only possible to the specialist.

To speak of the achievements of internal medicine is to conjure up the clinical experience of the ages, out of which it is an evolution, and the entire array of physical sciences, which internal medicine has made tributary to its special requirements. To trace the one or catalogue the other would be impossible on this occasion, and only a few illustrations can be offered.

Consider, for instance, the liver in its clinical aspects. One of the jokes which we are fond of cracking at the expense of our predecessors is that for them the liver, like a mantle of charity, covered their ignorance of the real pathology of many of their cases. This was really true, but it is strange how close their intuitions or accident led them to the present attitude of scientific medicine. It is true that the ground is entirely different. Then it was empirical; now it is accurate, scientific knowledge. Taking advantage, for instance, of physiological investigations, we avail ourselves of the phenomena of alimentary levuloseuria, to which I will refer more at length later, as an accurate test of the very important glycogenic functions of the liver, which it is believed bears a very close relationship to its antitoxic function. The significance of the

last named function is established by a variety of facts, clinical and experimental. I may mention the much greater effect produced by almost any toxic material thrown directly into the general circulation by the subcutaneous route, than when reaching it through the portal circulation and liver; and especially the phenomena of the Eck fistula, by means of which the portal blood is carried past the liver into the inferior vena cava, thus entirely robbing it of the detoxicating processes of the liver cells, and leading in consequence to the most profound auto-intoxication, as shown by ataxia, epileptiform and tetaniform spasms, blindness, etc. While these different liver functions (as well as others of which we know little or nothing at present) are distinct entities, yet they must be mutually more or less interdependent because of their anatomical associations. It has been shown, for instance, that if a small twig of the hepatic duct is ligated the glycogen disappears from the lobules from which it is derived. The contention, therefore, of von Noorden and Straus that jaundice, which is probably always due to obstructive disease in the biliary passages, does not interfere with the glycogenic function, must be received with reservation. It will thus be seen that, taking advantage of data such as those just recited, together with other quite familiar facts relating to the biliary and other functions of the liver, we are able to attack the associated clinical problems along clear cut lines in a manner which would have been impossible a generation ago.

The clinical study of the heart offers another example of the striking progress made in so many departments of internal medicine. From Laennec to Mackenzie, less than a century, reads like a romance. It was a great advance when the normal sounds of the heart could be heard and interpreted, and still more when pathological variations were recognized by a combination of clinical study and work in the autopsy room. Step by step the great work has proceeded, and is proceeding. The introduction of graphic methods constitutes the greatest single step, purely clinical in character, since the time of Laennec. By means of these methods several cardiac events can be simultaneously recorded on moving slips of paper. The rate of motion being known, the absolute time occupied by these events and their time relations to each other can be accurately determined. A comparison of these findings in pathological cases with those which normally prevail gives information of the highest value to the clinician. It has been found, for instance, that the ventricle should contract within a certain average time after the contraction of the auricle. The lengthening of this period, which can be accurately measured whenever a recordable pulsation exists in the jugular vein, may be the first indication of Stokes-Adams disease, and may probably exist long before the characteristic syndrome appears. These methods are borrowed bodily from the physiological laboratory, as is the determination of blood pressure, variations in which are not only of great pathological importance, but have been brought to a greater or less extent under the direct therapeutical control of the clinician.

Neurology offers striking examples of the remarkable progress which has characterized internal medi-

cine in recent years. The variations of the electrical reactions of muscles, by means of which we are able to distinguish between the peripheral and central location of a lesion of the motor apparatus which is causing a motor paralysis, may be mentioned as a noteworthy application of physical laws and physiological phenomena to the elucidation of clinical problems. Such routine procedures become commonplace, and we lose sight of the profound scientific knowledge, the laborious research, and the logical analysis that have made them possible.

In like manner the localization of brain lesions, which is now possible in many cases, marks another great triumph of diagnostic methods based upon experimental and morbid anatomical studies. The examination of the cerebrospinal fluid obtained from puncture of the lumbar spinal canal, or general ventricular cavity of the brain, often gives accurate knowledge of the highest value. The intraventricular pressure can be directly measured, while the cytology and bacteriology of the fluid may easily clear up the pathology of an otherwise obscure case. And so on through chapter after chapter of clinical research, which has built the imposing structure of modern neurology, a department of internal medicine large enough and complex enough to easily accommodate the energies of any one.

The diseases of metabolism form a group the recognition of which as such would not have been possible a few years ago. Their importance is indicated by the prevailing view, which appears to be well grounded, that every function of every organ and tissue of the body is dependent upon certain chemical processes, the correct performance of which within the range of fairly well defined physiological variations is absolutely essential for the maintenance of that state which we call health.

Perversions of these chemical processes constitute disease, the manifestations of which may vary from transient languor to a rapidly fatal coma; from a fugacious pain in a nerve trunk to a widespread, multiple neuritis or a myocarditis or a nephritis. The whole subject constitutes one vast, dark continent, which has been explored a little here and a little there, with most encouraging and even at times brilliant results. Carbohydrate metabolism may be mentioned as one of the most important aspects of the entire subject, because of its essential relation to the dynamics of the body, and the consequently large quantities in which carbohydrates are taken. After absorption their transformation by the liver into glycogen, and their ultimate oxidation, or, as it is termed, glycolysis, are the two clinically important facts. The failure of the last named function is the basal fact in diabetes mellitus. It is frequently impaired in the absence of the outspoken diabetic syndrome, and can be directly tested by the presence or absence of alimentary glycosuria after giving definite amounts, usually 100 grammes, of glucose. This is an important point in the study of chronic nutritional disease.

Within a few years we have solved the problem of clinically determining the glycogenic function of the liver by the administration of sufficient levulose to produce glycosuria. If this function of the liver is intact the levulose will be converted into glycogen, which is dextrorotary; if not, the levulose passes un-

changed through the liver, giving levulosuria, as determined by the polariscope. This is a great advance in internal medicine, giving us positive information of one of the principal functions of this most important glandular organ.

In nitrogen metabolism I will only mention the important discovery that creatinin rather than urea correctly represents destructive tissue metamorphosis; and the rôle that the purin bodies, some of which are undoubtedly toxic, seem to play in morbid metabolism.

Reference should here be made to that phase of metabolism represented by the internal secretions. The thyroid, parathyroid, and adrenal bodies, and the pancreas, through their internal secretions, occupy a position of great prominence in clinical medicine, although it is probable that all other glandular organs in the body furnish similar secretions, with functions quite possibly of equal importance. The investigations of the thyroid bodies has, in the opinion of many, myself included, very nearly cleared up the pathology of exophthalmic goitre and myxœdema. These syndromes are practically identical with hyperthyroidism and hypothyroidism. The cause of these changes in thyroid secretion is of course the undiscovered factor.

By the light of Ehrlich's brilliant generalizations antibodies have been produced in the blood of the lower animals which have a measurably successful therapeutical application as antidotes for the excessive thyroid secretion of exophthalmic goitre. What an achievement, to thus deliberately produce a chemical substance in the blood of an animal which does, without a doubt, combine with and render innocuous another chemical substance produced in morbid excess, with disastrous results, in man. The biochemical law which governs the production and operation of an antibody, antidotal to the active principle of thyroid secretion, is precisely the same as that which produces on neutralizing a bacterial toxine. These chemical bodies have never been isolated, and very possibly never will be; and we know therefore nothing of their chemical constitution, yet we are just as certain of their existence and can therapeutically manipulate them with about the same precision as though they were thus demonstrable. The medical aspects of exophthalmic goitre have been completely changed. In many cases we are getting striking results, although in others but little benefit accrues, indicating differences of pathology not yet understood.

On the other hand, myxœdema and cretinism have yielded brilliant results to thyroid feeding. Few more striking contrasts are ever seen than those offered by some of these patients before and after a course of thyroid treatment.

There is ground for hoping that Addison's, like Graves's, disease may be made to yield to therapeutical efforts based upon our knowledge of metabolism as influenced by the adrenal secretion. In one series of ninety-seven patients, about 17 per cent. were cured and about 32 per cent. improved, in a disease that is otherwise substantially always fatal. In nearly one half the cases no effect was observed. Here again, as in Graves's disease, there are possibly different types presenting unknown but fundamental differences in pathology.

Closely related to metabolic disorders are the phenomena of bacterial infections, and especially the defense of the organism against them. As already indicated, the same biological laws that govern the defensive operations of the animal organism against chemical poisons of metabolic or dietetic origin are concerned in bacterial processes. Antibodies are formed in response to any chemical poison that finds its way into the circulation. The very term poison is, however, open to objection. We know, for instance, that antibodies are formed to neutralize the secretions of the thyreoid gland. This occurs in perfect health while the gland secretion is normal in every respect. Now, it would be absurd to call an essential secretion the absence of which is the cause of so terrible a disease as myxœdema, and a fundamental fact in cretinism, a poison. Yet we have only to turn to Graves's disease to see how disastrous its excess may be. The broad fact which internal medicine possesses as one of its most valuable assets, and which is one of the most striking generalizations of modern science, those of the stellar universe not excepted, is that among the biochemical processes of the body provision is made for the formation of antagonistic chemical bodies capable of more or less completely neutralizing nearly every chemical substance which finds its way into the general circulation. The therapeutical application of these basal laws will widen with our mental vision.

But this is not all. The scheme is not merely defensive, but is offensive as well in the case of bacterial processes. Not only are the bacterial poisons neutralized by antidotal chemical bodies, but the bacteria are themselves directly attacked and destroyed in a variety of ways. I will only refer to one. Ten years ago Denys and Leclef made the remarkable discovery that chemical bodies in the serum prepared microorganisms for destruction by phagocytes. It was recognized as a brilliant scientific discovery but was not supposed to be of clinical interest. To-day, thanks to the labors of Wright and his followers, this great discovery is receiving daily clinical application all over the world, under the title of opsonic or vaccine therapy. We are able at will to increase the efficiency undoubtedly by increasing the amount of those chemical bodies that prepare bacteria for phagocytosis, and which, after Wright, we call opsonins. Its possibilities, especially in the chronic infections, like tuberculosis, can scarcely be overestimated. The technique will, we hope, be ultimately simplified so as to place it on a more practical basis, and permit of its wider use. While its limitations have scarcely been accurately defined, it is safe to say that it has taken a permanent place in the armamentarium of internal medicine.

Such are a few of the achievements of internal medicine, which, in its special sense, is simply clinical medicine specialized by a breadth of knowledge and technical skill, of which that possessed by the general practitioner forms a larger or smaller part according to his mental and material equipment. If time permitted the list could be greatly enlarged, but these are sufficient to indicate the progress already made and the character of the work now being done.

The future is full of promise, and the labor of those engaged in this fascinating but extremely arduous field of professional work will, there is good reason to believe, still further broaden both our knowledge of internal diseases and our therapeutic resources for their control. This is one of the greatest advantages of specialism everywhere. It is the concentration of thought and energy along special lines that has led to the greatest advances in the world's history. It is just as true in medical specialism as elsewhere.

In conclusion I cannot refrain from reproducing a paragraph quoted by a contemporary medical journal from the *New York Evening Post*. Coming from a lay source it is particularly gratifying, and shows a keen appreciation of medical affairs. The writer says: "Some of us forget, too, the developments in medical science due to the incessant labors of the specialist. To him we owe the prodigious advances of medicine and surgery in the last generation, the incalculable alleviation of suffering and the saving of life. The perfection of an antitoxine may take the best thought and energy of a specialist for fifteen or twenty years. The resulting benefits to mankind, as in the case of diphtheria antitoxine, cannot be reckoned in money. An inventor who should expend half the time and skill on a contrivance of infinitely less intrinsic worth might easily win a fortune. But the medical specialist reaps no reward whatever, beyond, perhaps, a slightly increased practice, due to his added prestige. Often, indeed he deliberately sacrifices his practice, or even his life, to the advancement of science. For every new discovery in medicine and surgery, every new specific, every new process or device is at once offered freely to the whole world. The doctor who makes a secret of his drugs or operations is instantly ostracized. Generalizations are dangerous," concludes the writer, "but it is safe to say that no one class of men has given mankind so much and received so little material reward as the medical specialist. His greatest recompense is the consciousness that he is the servant of the ideal."

407 WEST MAIN STREET.

#### INDICATIONS FOR WATER IN CHILDHOOD.\*

By MAX BARBOUR, M. D.,  
Philadelphia.

A child is an adult in miniature. All the physiological laws operative in the grownup are similarly operative in the infant, while most of the diseases affecting the adult are also affecting the young. Therefore, all those principles underlying the study of the proper care and treatment, both in health and disease, of the adult patient must likewise be applicable to the study of the care and treatment of the infant patient.

Barring such conditions to which only children are subject, we may safely consider this question from a general standpoint, leaving the particular diseases of childhood for special consideration.

Physiologists tell us that the animal body consists of almost 70 per cent. of water. Admitting this to be true, it would seem plausible to believe that this

\*Read before the League of Medical Societies.

quantity is necessary in order to carry on the normal physiological processes of the animal economy in proper condition. For similar reasons it would also appear plausible that should this quantity in any way be greatly reduced or diminished, either through normal processes of the body—such as exhalation, perspiration, and excretion—or through abnormal processes—such as fevers, diarrhoea, or loss of blood—this lost quantity must immediately be resupplied. Failure to do so will inevitably disturb the normal physiological balance and will result in bodily disorders of various forms.

Should such a withdrawal of water be permitted to be unduly prolonged, the disorders will assume such grave dimensions that life itself may ultimately be terminated. For life cannot be sustained without a constant renewal of all elements requisite for normal physiological processes.

The rôle which water plays in the animal economy is distinct and definite and is vitally important. It cannot be replaced by any other ingredient, and must in itself be of sufficient quantity to be utilized to advantageous purposes. Among its most important functions may be mentioned that it enters into chemical composition with all tissues of the body; and all tissue changes depend entirely upon a sufficient quantity of water. It forms the chief ingredient of all the fluids of the body and maintains a proper degree of dilution. It moistens the variety and serous surfaces and prevents friction and such other symptoms as will result from drying. It furnishes the blood and lymph with a proper fluid medium by which food may be carried to distant parts of the body and the waste products removed, thus promoting normal tissue changes.

Elasticity and pliability of muscles, nerves, cartilage, tendons, and even bones depend mainly on the amount of water they contain. Water also serves as a distributor of bodily heat and regulates the body temperature by the physical process of absorption and elimination. In fact, all protoplasmic activity is greatly impaired and may even entirely cease when a lack of water becomes felt. And truly has an eminent author expressed himself that "the cells of the body are aquatic in their habit." From the cursory enumeration of facts pertaining to the physiological rôle of water in the animal economy, it becomes evident that its normal percentage must at all times and under all circumstances be properly maintained, so that bodily functions be not materially interfered with.

Under normal conditions and in a proper degree of health, this supply is ordinarily furnished partly by the food and partly by the drink we are daily consuming. An overindulgence in the use of water—provided it is not carried to excess—will scarcely, if ever, be productive of any deleterious consequences. Such excess is ordinarily only of a temporary character and is immediately relieved by the increased glandular activity. And, instead of exerting an unfavorable effect, enhances excretion and metabolism. Should this increased ingestion of liquid be continued for some time, its favorable effect will only be augmented and made lasting. For a plentiful supply of water increases the volume of blood, stimulates the activity of the glandular structures, increases the action of the kidneys, and pro-

motes sweating. Hence the tissues of the body will be more abundantly supplied with blood and more readily rid themselves of any dead or inactive tissue cells. The salivary, biliary, pancreatic, and intestinal juices will be increased, and improved digestion and assimilation will result in consequence.

By an increase in the flow of urine, the kidneys are washed and cleansed of any toxic substances that may be found there. Moreover, by taking much water into the stomach, it dilutes the food and helps digestion, or, if the stomach is empty, it washes out of it any possible mucus; and, what is still more important, by its mechanical pressure, excites peristalsis, and, passing into the intestinal tract and acting in a like manner, produces a mild laxative effect. The perspiration is increased and a larger amount of aqueous vapor is exhaled from the surface of the lung. In consequence of these activities, the used up material of the body is speedily removed, and the organism is enabled to take up a larger quantity of new nutritive substances. Body weight is thus easily gained. Hence the popular lay idea that "water is fattening" can well be explained upon this ground.

Contrasting the results attained by a deprivation of water and by a liberal supply of same, we find the following conspicuous facts preponderately in favor of the latter. An insufficiency of water will dry up the secretion of the glands, arrest its activity, and diminish its quantity, thereby inhibiting digestion and other physiological processes; while a plentiful supply will engender increased activity and impart additional tone and vigor. Insufficient water will diminish the volume of the bloodvessels, inspissate the quality of the blood, and lessen the quantity, thereby inhibiting the circulatory power with probable results of forming thrombi in the smaller veins of the distant parts of the body, such as the brain or legs. Should the thrombus lodge in the brain, convulsion will follow, especially in children, and if in the leg, gangrene is apt to set in. A liberal supply of water will prevent such calamitous consequences.

Abundant supply of water increases the elimination of urea and carbonic acid; relieves the kidneys from undue irritation and injury; removes the waste product from the tissue and enhances metabolic activity; while a deficiency of water diminishes the quantity of urine, retains the degenerative tissue products, and causes absorption of ptomain products from the gastrointestinal tract, kidney, and other glands. The advantages derived by a plentiful supply of water cannot, therefore, be overestimated. Its indications are not only clearly defined, but peremptorily imperative.

Fortunately Nature has provided a safe guide by which a deficiency of water is readily detected. The condition of the system known as "thirst" is an exact exponent of the dryness of the tissue and a clear indication for the ingestion of liquid. The individual thus suffering is guided by his personal inconvenience and instinctively supplies the necessary quantity and keeps the body in a normal physiological equilibrium. But the physiological equilibrium can properly be maintained only in the grown ups, who feel their wants and know how to satisfy them. But the matter assumes an entirely different aspect when the question of childhood comes to be considered.

A child cannot in so many words ask for water, nor does it even understand the pangs of thirst. Yet it is clearly certain that the child requires water to carry on the physiological processes of its rapidly growing system as surely as an adult. In fact, it needs more water than the adult. According to Holt and Jacobi, the child requires, proportionately to its weight, six to eight times as much water as the adult.

Considering the physiology of the child, there are sufficient data to warrant the administration of infant's food in a very diluted form, even to the extent of 80 to 90 per cent. According to Holt, such a percentage of water is normally constituting the foods of all young mammals. Its use becomes apparent when we learn that this amount is really needed to dissolve certain ingredients in the food, such as sugar and salts; keep other substances in suspension, such as proteids; and also to emulsify fats.

Another and very important consideration, which is too frequently overlooked, is the child's digestive power. The child's stomach does not secrete as plentiful a supply of pepsin as does that of the adult. And the meagre quantity that is secreted is not always completely utilized, unless a liberal quantity of water is added. This is especially true in artificial feeding, where the albumin will often remain unchanged unless the child will be given some acidulated water.

According to Thompson, "One of the most universal dietetic failures is neglect to take enough water into the system." I have had many occasions to observe the correctness of his assertion. The very frequent occurrence of vomiting in children after having taken the breast I have frequently allayed with no other medicament than the administration of a few teaspoonfuls of water. The water, of course, should, for safety's sake, always be boiled. The idea is ordinarily entertained that the milk is in itself sufficiently diluted and requires no additional dilution. But those who think so forget that when the milk reaches the stomach it turns into curd, which is almost a solid, and with the child's feeble digestive power and with the meagre quantity of pepsin supplied, digestion will be considerably hampered unless water be given. And should this state of affairs continue for some time, irritation and subsequently inflammation of the gastric mucosa will follow.

From these facts we can see the rationality of advising mothers and nurses who take care of children to give them water and plenty of it. A glass of water during the twenty-four hours for an infant of several months is none too much. This amount should vary according to season and to certain physical conditions of the child. During the hot summer months, the child will require much more water than during any other time. In a state of perfect health, the child may receive a little less water, but during certain morbid conditions the quantity should be either considerably increased or considerably diminished.

It is not within the scope of this paper to state the therapeutical value of water in each particular disease, but I will only outline certain indications in a few diseases, leaving the physician to exercise his good judgment in the definite case under his

consideration. The morbid states in which water is particularly indicative are those that are accompanied by pyrexia. Fever consumes a great deal of water from the tissues, diminishes the secretory power of the various glands and especially lessens the secretion of the saliva and gastric juice. It also inhibits the absorbing power of all the mucous membranes. By giving enough water to the child, it will restore the loss sustained through the fever, enhance the glandular activities, and by diluting the food, the gastrointestinal tract will more readily be able to absorb the nutriment and maintain the vitality of the child.

In gastrointestinal disorders, a condition very frequently occurring in childhood, water is of inestimable value. Most of the cases of gastric disorders are due to overfeeding. The pernicious habit of giving the child the breast or food whenever it cries has led to many an ill consequence. Many mothers will not appreciate the fact that "a child may be thirsty without being hungry at the same time." And if food instead of water is given, the delicate stomach of the child will be overloaded, irritated, and inflamed. The treatment is simple—give less food and more water.

In the various forms of diarrhoea, particularly the summer diarrhoea, with stools numbering fifteen to twenty a day, or in protracted and chronic forms of diarrhoea, the reason for administering large quantities of water is selfevident, for watery stools abstract the fluid from the system, diminish the blood pressure, and cause a decided depression in the vital powers. The loss of liquid thus sustained must of necessity be rectified, either by administering water by mouth or per rectum.

By imbibing a quantity of fluid we raise the arterial tension, reinforce the bloodvessels, supply the dried up tissues with the adequate amount of fluid, enhance metabolism and counteract the depressing effect of the diarrhoea. In cases of general inanition or where metamorphosis is very slow, water will prove a decided benefit by increasing elimination of waste products and engender greater physiological activity of the system. In conditions where the urine is scanty and of a high specific gravity, water will wash out the kidneys from irritating substances and protect them from undue injury.

In irritability of the bladder due to concentrated or acid urine, water will prove an unquestionable beneficial remedy. In laryngitis and bronchitis, ingestion of water will moisten the bronchial mucous membranes, liquefy the viscid expectoration, and act as a mild expectorant. There are many other conditions where the beneficial use of water is clearly evident. But they all rest upon the same physiological principle, viz., the endeavor to restore the system to as close a normal physiological process as possible. Upon the same ground and for similar reasons, the use of water should be restricted in all such conditions where it will tend to deviate from the normal physiological process.

Conditions where water in children are contraindicated are but too numerous. Many more are found in adults and especially in the aged. Atherosclerosis, aneurysm, cardiac insufficiency, dilatation of the stomach, etc., are certainly conditions

where abstinence from water is highly reasonable, but childhood being free from such diseases, such contraindications are out of consideration. There are, however, certain conditions where the restricted use of water is clearly advisable. Such cases as edema or pleuritic effusion where the extravasation of fluid into the tissues is great, water is certainly contraindicated. In cases where there is a high arterial tension with congestion or inflammation in certain organs, such as the brain in meningitis, or the lungs in acute lobar pneumonia, an increased ingestion of water will aggravate the condition by additionally distending the bloodvessels, and the withdrawal of water is unquestionably the proper treatment. In fact, in any condition where there is congestion in important organs as a result of acute inflammatory processes, the use of large quantities of water is contrary to good judgment.

Barring such conditions the use of water in children, both in health and disease, is certainly underrated to the lamentable disadvantage of the child. Water being so simple and commonplace a drug that it seems to be below dignity to devote to it any amount of attention. Hence, its proper treatment in our works on therapeutics is sadly omitted. Yet if doctors, nurses, and mothers would give "our little ones" water more often, there would be less occasion to give drugs so often. Between the two, I would rather see the child be the reservoir of the harmless, yet all beneficent, water than a receptacle for an infinite variety of drugs which at best leave but an undesirable impression.

1037 SOUTH FIFTH STREET.

#### CONTRACTED PELVIS AS A CAUSE OF DYSTOCIA.\*

By JOHN OSBORN POLAK, M. D.,  
Brooklyn, N. Y.,

Professor of Obstetrics, Dartmouth Medical College, Albany, N. Y.  
and of Obstetrics and Gynecology, Long Island  
College Hospital.

Actual or relative deformity of the pelvis occurs with sufficient frequency to make it a common factor in causing dystocia during labor. All dystociæ are due to some defect in the powers, the passenger, or the passages, and this latter cause is the least comprehended by the practitioner, yet actual contraction of the pelvis showing from one half to one inch deficiency in the anterior posterior diameter occurs in about 6 per cent. of American born women and a relative contraction is present in a larger percentage. Fortunately both for the woman and the child the degree of contraction is slight. It is, however, these slight degrees of contraction which produce foetal malpositions which result in the dystocia so commonly met. Marked contraction, though rare, is more easily recognized, and the physician is therefore more able to cope with the complication.

The build of the woman, the history of her previous labors, the high position of a tumor, some degree of pendulous abdomen, the malposition of the foetus, and the nonengagement of the presenting part, all point to a disproportion between the passages and the passenger, and should suggest to the attendant the necessity of careful investigation.

The ability to recognize deformities of the female pelvis by pelvimetry is as necessary an accomplishment for the accoucheur as percussion and auscultation is to the internist.

The practitioner and many teachers are wont to discredit pelvimetry, failing to appreciate that its value is relative and suggestive, rather than accurate. For the birth of the child depends, not only on the size of the pelvis, but the size of its head, the degree of its adaptability, the character of the labor pains, and the resistance of the maternal soft parts.

The purpose of these remarks is to briefly sum up our position in the management of labors in contracted or relatively contracted pelves.

Contraction, whether actual or relative, can in most instances be recognized before labor by abdominal examination, noting the high position of the tumor, the marked protrusion of the abdomen (a pendulous abdomen in a primipara is always significant of a misfit), the frequent occurrence of malpositions, the high position of the presenting part, and finally by cephalometry and pelvimetry. In multiparæ the history of previous labor should put the attendant on his guard.

When labor has actually begun, the question which presents itself is, Can this child pass through this pelvis, and how?

Before going into the management of labors occurring in abnormal pelvis, I wish to take up a few minutes by directing attention to some simple points in pelvimetry and cephalometry, both actual and relative, too often passed over by the attendant as scientific rather than practical.

The external conjugate or diameter of Baude-locque simply serves to indicate the probability or improbability of pelvic contraction. An external conjugate of 16 cm. or under always means an anterioposteriorly contracted pelvis. When this diameter is between 16 and 19 cm., the pelvic inlet is contracted in more than 50 per cent. of the cases. When above 21.5 cm., it is almost certain that the inlet is ample.

This diameter, which is measured from the fossa below the spinous process of the last lumbar vertebra to the front of the symphysis, about one eighth of an inch below its upper edge, averages in the normal pelvis 20.25 cm. The relation of the iliospinal 10 inches or 26 cm. to the ilioecristal 11 inches or 29 cm. is all important, for the former should always measure less than the intercristal, in a normal or generally contracted pelvis, while in a flattened pelvis the interspinal is often equal to or greater than the intercristal in length. Occasionally external pelvimetry, and the suggestive data thus gained is unavailable for one reason or another, and the practitioner must fall back on the only reliable measurement in the true pelvis, the diagonal conjugate, which is measured from the summit of the subpubic arch to the promontory of the sacrum; from this the conjugate vera may be estimated by deducting from one half to three quarters of an inch, depending upon the depth, the inclination, and the thickness of the symphysis. It is safer, however, always to deduct three quarters of an inch. A rough, yet practical, way of estimating the true conjugate is to estimate the diagonal conjugate by digital examination, basing such estimate on the ease with which

the promontory can be reached. (If it cannot be or can just be touched with the middle finger, the anterior-posterior may be considered normal, while if the promontory can be reached with the index finger the pelvis is contracted, and the contraction is in proportion to the ease with which the promontory may be reached.)

When extreme accuracy is demanded, as when it is necessary to decide between hebotomy during labor or an elective Cæsarean operation, Hirst's pelvimeter for measuring the distance between the upper outer edge of the symphysis and the promontory, and then deducting the measured thickness of the symphysis, seems to leave but little room for error. The outlet diameters may be accurately measured.

After determining the size of the pelvis, its relative capacity must be estimated by noting the size, compressibility, and malleability of the fetal head, for an normal pelvis may be an insuperable obstacle if the child is large. In primiparæ when there is a normal relation between the head and the pelvis, the presenting part descends into and engages in the pelvic cavity during the last week or two of pregnancy, consequently when the head is not engaged in a primipara at the beginning of labor something must be wrong. *This rule has no exception.* Any of the following causes will prevent the head from being found engaged: a contracted pelvis, a large head, a small child, excessive liquor annui, malpositions of the fetus, multiple pregnancy, and placenta prævia. Vertex presentations are 10 per cent. rarer in contracted pelvis than when the pelvis is normal; abnormal presentations increase in frequency with the degree of contraction. Face and transverse presentations possess a peculiar significance in primipara, as such a malposition always suggests disproportion.

Before labor, Stone's method of estimating the biparietal diameter of the fetal head is of great practical value. He measures the occipitofrontal diameter with a pelvimeter through the abdominal wall, making no deduction for the thickness of the parietes—2 cm. is subtracted from the occipitofrontal if this diameter is 11 cm. or less—and the resultant is the biparietal; when the occipitofrontal is over 11 cm., 2.5 cm. are subtracted.

When labor has begun or is in progress, and the head remains unengaged—with the occiput to the posterior in semiflexion or in some degree of extension, which is always an evidence of dystocia—the attendant may gain an excellent and accurate idea of the relative size of the head and pelvis by adopting the following modification of the so called Mueller's method:

With the patient on a table, anæsthetized, and in the Walcher position, her bladder and rectum empty, the vulva and the hands of the operator properly cleansed, one hand is introduced through the vulva and passed into the vagina, or, if necessary, into the uterus, the head is seized, flexed, and rotated in such a way that the sagittal suture is either in an oblique or the transverse diameter at the brim. With the head held in this position by the vaginal hand, the external hand attempts to crowd it into the superior strait by suprapubic pressure; if it enters and can be made to engage there (the

disproportion; failure to engage usually signifies actual or relative contraction).

When contraction of the pelvis is recognized before labor, the pregnancy may be interrupted before the fœtus has attained its full size by the induction of premature labor, or the pregnancy may be allowed to go to term, and the labor managed along normal lines with postural aid until some complication shall arise to threaten the life of mother or child, or the pregnancy may be terminated by premeditated intervention for the purpose of protecting mother and child, practised before or at the onset of labor, as version, hebotomy, or Cæsarean section.

Every case of labor in a contracted or a relatively contracted pelvis presents such distinct and definite indications, that it is difficult to formulate inflexible rules for its management. The writer's practice in this class of cases is briefly as follows:

If the conjugata vera measures as low as 9 cm., it is a safe plan to induce labor at the thirty-sixth week or thereabouts. Such a child has had but little added risk, and such a procedure is much the safest plan for the mother, for the induction of labor, if done properly, should have no maternal mortality. It will be contended that many women with a conjugate of 9 to 9.5 cm. will deliver themselves spontaneously at term, and while we know this to be true, the majority will experience abnormal delay and difficulty in labor, with added risk to both child and mother. Even in a pelvis with a conjugate of 8.5 cm. I practise induction at the thirty-sixth week and consider it the operation of choice. If, however, the conjugate measures 7.5 cm. or less, premature labor four weeks before term cannot be expected to assure spontaneous delivery, and the viability of the child is less as we get further from term. Cæsarean section, on the other hand, offers the greatest advantages, done at or shortly before term as an elective operation.

If the patient is seen for the first time in labor, or the deformity is not recognized until labor has already begun, it is well to permit the labor to proceed, noting the character of the pains, the moulding and adaptation of the head, and allow, if possible, the engagement of the head by natural forces. It is permissible in most cases to wait for full or almost full dilation of the cervix, noting the woman's pulse, temperature, her general condition, and the height of the retraction ring, and the thinning out or distension of the lower uterine segment, to avoid the possibility of uterine rupture. Should the head fail to engage by natural forces while the cervix is dilating, it is my practice to attempt to fit this head to the pelvis by the modification of Mueller's method already described, taking advantage of the Walcher position during the manipulation—should this fail to secure the entrance of the head into the pelvic inlet, Nature and forceps, in my opinion, should give place to podalic version, when the conjugate is not below 8.5 cm.—as the smaller end of the wedge represented by the child's head is engaged in the contracted inlet, the head may be guided through the successive diameters with great facility, for not only is the vault compressible by the overlapping of the parietal and occipital bones, but by traction of the body and pressure on the head, from above, through the abdominal walls

greater force in the proper axes can be exerted than with forceps. If in the judgment of the operator the danger to the child is too great by version, either because of the large size of the child or because the pelvis is less than 8.5 cm., hebotomy or Cæsarean section must be employed, the latter always in pelvis of 7 cm. or less, provided, of course, that the child is living.

Perforation in contracted pelvis has a large field when the child is dead or dying, particularly when the woman is exhausted and has a high retraction ring. The operation simplifies the delivery and should be elected. It must be remembered, however, that embryotomy should only be attempted in pelvis above 7.25 cm., and is safer as the antero-posterior diameter is larger.

287 CLINTON AVENUE.

### THE NERVOUS AND MENTAL MANIFESTATIONS INCIDENT TO SCHOOL LIFE.

BY WILLIAM RUSH DUNTON, JR., M. D.,  
Towson, Md.,

Assistant Physician, Sheppard and Enoch Pratt Hospital.

So much has been written upon the subject under discussion that it would seem useless to spend any prolonged time in introducing it, as doubtless much of the literature is familiar to you. Less than a week ago a paper by Dr. Hollopeter appeared,<sup>1</sup> which had been read several months earlier, in which he makes a special plea for the physician to interest himself in the subject in order to educate the parents to a proper conduct or oversight of the child's mental and physical health. Dr. Hollopeter makes a very interesting comparison between the standards established for certain school grades in 1888 and the present, showing that there has been a considerable advance in the intellectual requirements of school children. He believes—and I think the majority of physicians will agree with him—that there is great danger in advancing the intellectual standards, as a considerable degree of mental overstrain may result, with the consequent mental impairment of the child. In some schools it is possible that the danger line has been transgressed. Dr. Hollopeter makes a special plea for the backward child, alleging that the teacher should bestow greater attention upon him than upon his more brilliant brother, and, as a gauge of the capacity of the child for learning, Dr. Hollopeter suggests that the attention be used, and in this I heartily concur. There are many other good papers upon the subject, and I should like briefly to refer to them, but time does not permit, and it is presumed that a number of them at least have been read by you.

It must be remembered that for a considerable part of the child's school life he is passing through a critical period, that of adolescence, and that overstrain occurring then will usually be attended by far more serious consequences than overstrain occurring later.

Concerning teaching, in *Adolescence*, page xii, Dr. Stanley Hall says: "Reading, writing, draw-

ing, manual training, musical technique, foreign tongues and their pronunciation, the manipulation of numbers and of geometrical elements, and many kinds of skill have now their golden hour, and, if it passes unimproved, all these can never be acquired later without a heavy handicap of disadvantage and loss. These necessities may be hard for the health of body, sense, mind, as well as for morals, and pedagogic art consists in breaking the child into them sometimes as intensely and quickly as possible with minimal strain, and with the least amount of explanation or coquetting for natural interest, and in calling medicine confectionery. This is not teaching in its true sense so much as it is drill, inculcation, and regimentation. The method should be mechanical, repetitive, authoritative, dogmatic. The automatic powers are now at their very apex, and they can do and bear more than our degenerate pedagogy knows or dreams of. Here we have something to learn from the schoolmasters of the past back to the Middle Ages, and even from the ancients." I hardly think that the majority of physicians will agree with Dr. Hall in his opinion, and personally I feel that it is through just such means that the child is subjected to overstrain.

In all probability an inquiry made among this company for the purpose of determining what is considered an ideal school life would bring forth many different opinions, and we should doubtless have some difficulty in coming to an agreement as to what constitutes the ideal conditions under which a child should study, but I think that the majority of persons who have investigated or thought upon this subject will agree that attainment of the following will go far toward reaching an ideal. In the first place, after having submitted to all laws of hygiene by providing a healthy place in which the child may study, we must see that the hours of study are not too long and that they are interrupted by periods of play, which not only permit a relaxation of muscles but also a relaxation of the attention. The child may not be conscious of any feeling of effort, but we know that to a greater or lesser degree it is present, and must be ended before it has gone too far. Second, the manner of learning should follow as closely as possible the natural method of thought, and by association "facts and figures" should be acquired rather than by arbitrarily making memory impressions, as most of us learned the multiplication table. As an illustration of how little the child may learn from this arbitrary memory method I would say that some time since I was talking with a teacher in this city concerning the progress made by a child in whom I happened to be interested, and who had, up to her thirteenth year, been educated in one of the public schools of Pennsylvania, and was told by the teacher that, while the child apparently did fairly well, in reality she did not, and, as an example of her comprehension of history, he stated that, while this pupil knew that Sir Walter Raleigh was one of the courtiers of Queen Elizabeth, she probably did not appreciate the fact that Sir Walter Raleigh was a man. This child was apparently bright and most certainly could not be classed as mentally defective, so that I am forced to conclude that the method of instruction in her case was not what was required. As a third require-

<sup>1</sup>Published in the *Journal of the American Medical Association*, New York and Chicago, Vol. 1, No. 1, p. 1, 1917.

ment of ideal study conditions, there should probably be not more than twenty nor less than ten pupils under the charge of a teacher, although on this point I do not speak so positively, as I have not had an opportunity to experiment; but it seems to me that a teacher cannot well control more than twenty scholars, and a less number than ten does away with a feeling of rivalry or of companionship, which may be made of considerable value. Fourth I would place the teacher, not because I do not believe he is most important, but because experience has proved that, even although he may have mannerisms or methods which are distinctly bad, we find that the pupils learn despite them. The personal influence of a teacher is tremendous, and in many cases serves to make or mar the pupils, but in just as many perhaps this influence is without any but temporary effects. In our list of requirements for an ideal school life it seems that the teacher occupies a varying place. If we can have a perfect one he should be placed first, but if he has imperfections he may be placed last.

In this discussion it is hoped that we physicians may learn something from the teachers in order that we may instruct parents, and also that we may be able to show the teachers how certain diseases may have mental effects which interfere with the pupil's power to acquire knowledge. Besides the introduction of the subject, my own part includes mention of the nervous and mental diseases which we may find in school children, and which have a direct effect upon the pupil's ability to learn or which may affect his fellows.

In the first group I would place chorea, which is undoubtedly the most important of the nervous diseases met with among school children, because it is so frequent, and because parents and teachers do not seem to recognize the fact that the subject of even the mild forms shows defects of memory and attention which are sometimes interpreted as being due to sulkiness or ill temper. It is the wisest course to withdraw the child from school, as his best interests are thus served, and the other scholars are not liable to develop tics or habit spasms, as they may, by watching his movements.

This last statement also applies to the subject of tics and of epilepsy, and probably it is the companions of the subjects of these last diseases who should be most considered by the teacher rather than the individuals themselves. Both the ticer and the epileptic should be so seated that they are not observed by the other pupils, and if the epileptic has an attack during school hours he should be laid upon his back, the clothing loosened about his neck, precaution taken to prevent his biting his tongue by the insertion of a piece of wood or some other form of mouth gag between his teeth, and after the convulsion has subsided he should be permitted to rest quietly until consciousness returns and he is able to go home. The resumption of the interrupted school work as soon as the convulsion has subsided will go far toward dispelling the mental shock to the pupils occasioned by the convulsion. Should the epileptic have frequent attacks, he should not be allowed to attend the general school, but should be forced to attend a special school or special class. The teacher should bear in mind that frequently these patients

have an irritable disposition, and that following the convulsion there may be a condition of automatism in which the patient is not responsible for his acts. It should also be borne in mind that there is usually mental dulling, which is frequently increased, I regret to say, by the injudicious administration of bromides by the physician, and that the epileptic must therefore be regarded in many instances as a backward child.

Hysteria with its multiform manifestations may be encountered, and the teacher can wield a tremendous influence for good in these cases by inculcating habits of proper mental hygiene.

Nervous exhaustion, or neurasthenia, may be met with, and here the most conspicuous symptom may be the tendency to fatigue, both mental and physical.

These are the principal nervous diseases which the teacher may encounter, and in all of them the attention may be used as an index of the power of the child to learn, although the memory will also serve as an additional point for observation.

Of the mental diseases but two are commonly met with among school children, and these are imbecility and dementia præcox. Of the former there may be all grades, from the one who is but little above the idiot to the one who is bright intellectually but deficient in moral sense, the so called moral imbecile. It is a condition which is unfortunately fairly common and easy to recognize, so that it needs but to be mentioned.

Of dementia præcox, on the other hand, there is so much that should be said that I am not going to make the attempt, as there is not sufficient time, and instead I am going to recommend that you all read a paper by Dr. Smith Ely Jelliffe entitled *The Signs of Prædementia Præcox: Their Significance and Pedagogic Prophylaxis*, which appeared in the *American Journal of the Medical Sciences* for August, 1907 [cxxxiv, p. 157], and which contains all that I want to tell you and more. I am sure that by a perusal of this paper you will be helped more than you could by any brief résumé of the subject which I would have to give you at the present time.

**Proposed Chinese College of Medicine.**—Consul W. T. Gracey writes to the Department of Commerce and Labor from Tsingtau that it is reported that, according to the wishes of Viceroy Chang Chitung, a college of medicine is about to be opened at the Chinese capital. Preliminary plans include the following measures: As the school is to afford the highest medical training for the young men of the entire Empire, it shall not employ men on its faculty who do not come with the highest possible recommendations. In accordance with Chinese ideas the course is to be divided into three years of old Chinese medical practice and six years of modern Western training. At the end of these nine years there is to be a thorough examination, and then three more years of study and trial practice shall be demanded before the students shall be qualified doctors. This examination must also be passed by people who are now practising on certificates from existing medical schools. No one who does not hold a literary rank of a fixed grade (*shên*) shall be allowed to take these examinations, regardless of where he studied.

## Our Readers' Discussions.

## A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXX.—How do you distinguish alcoholic stupor from other conditions resembling it? (Closed January 15, 1908.)

LXXI.—How do you treat gallstone colic? (Answers due not later than February 15, 1908.)

LXXII.—How do you treat fracture of the patella? (Answers not later than March 10, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXIX has been awarded to Dr. Maurice A. Walker, of Dillon, Montana, whose article appeared on page 164.

## PRIZE QUESTION NO. LXIX.

## THE TREATMENT OF POST PARTUM HÆMORRHAGE.

(Concluded from page 216.)

Dr. Glenn I. Jones, of Boston, remarks:

My experience has taught me that this formidable sequel is not so rare as to permit the obstetrician to attend a woman in labor without being fully armed to cope with it.

*Precluding and Preventative Measures.*—A thorough knowledge of the causes of this most frightful of obstetrical complications precludes the proper appliance of preventive measures, which is better than cure.

The predominating causes tending to post partum hæmorrhage and the conditions that are treated to cure the condition are: 1. Incomplete separation of placenta. 2. Retention of cotyledon. 3. Total absence or deficient uterine contraction. 4. Cervical lacerations. 5. Distension of bladder or rectum (causing sympathetic uterine inertia). All the other ætiological factors are simply predisposing conditions to one of these causes.

A thorough history of previous pregnancies and labors, an accurate, detailed gynecological and obstetrical examination of patient before impending labor, and an intelligent consideration of woman's general physical condition should all be of incalculable value in the preventive and precluding treatment.

The time of occurrence of hæmorrhage suggests the cause of bleeding, and I shall consider the condition as primary and secondary.

Primary hæmorrhage occurs before extrusion of placenta after childbirth, and is due to incomplete separation of placenta or cervical tears.

Secondary hæmorrhage occurs after expulsion of placenta, and is generally caused by retention of cotyledon, inertia uteri, or cervical tears.

A firm and permanent contraction of uterus, with hæmorrhage, occurring immediately after birth of child, before placental delivery, indicates bleeding from a severe tear. On the other hand, if uterus does not firmly contract and retract, bleeding must be looked upon as due to partial separation of placenta, retention of cotyledon, or atony of uterine musculature.

Some cases of post partum bleeding undoubtedly occur through the overconfidence of the accoucheur, who, accustomed to the monotony of normal labors, overlooks the following minute rules in the management of the third stage:

a. Observe the condition of uterus after birth of child.

b. Avoid resorting to Crede's method of expulsion until condition of fundus indicates complete separation of placenta.

c. Knead uterus immediately after delivery of child, to prevent relaxation.

d. Examine placenta immediately after expulsion to ascertain its integrity. If any defect is observed, immediate digital exploration of uterine cavity with removal of remnants should be done.

e. Empty bladder and rectum before labor.

*Actual Hæmorrhage.*—Hæmorrhage having occurred it is imperative that it be checked immediately, since the amount of blood lost is rapidly dangerous to life.

1. Before extrusion of placenta, (a) knead fundus firmly; (b) if uterus does not respond, placenta should be expressed by Crede's method and kneading continued; (c) this failing, manual removal with digital curettage becomes necessary; (d) have nurse or assistant make firm pressure over abdominal aorta in region of bifurcation.

2. After extrusion of placenta, ascertain cause and institute proper treatment. If due to lacerations, ligate bleeding vessel and do primary repair. If indications point to retention of particles of placental tissue, remove by digital curettage.

In all cases give fluidextractum ergotæ 5j by mouth and 3ss subcutaneously (in thigh) immediately. Follow this by morphine sulphate gr. ¼ subcutaneously. Have nurse or assistant massage breasts, lower head of bed, and knead uterus vigorously.

If hæmorrhage is not controlled, hot intrauterine douches of decinormal saline solution or hydrargyri chloridum corrosivum 1 in 40,000, followed by saline solution at temperature of 110° to 115° F., should be given until return contains no tinge of blood. This agent acts most efficiently, producing hæmostasis and irritating the uterus to forcible and permanent contraction.

Hæmorrhage persisting after these measures should be treated by tightly packing the uterus with sterile gauze.

Bimanual compression, producing temporary ante-flexion, limiting the cavity of the uterus, and stimulating contraction, is sometimes quite efficient in allaying the hæmorrhage. In all manipulations requiring the introduction of foreign substances into the uterine cavity the most rigorous aseptic tech-

nique should be observed. After hæmorrhage is checked the patient should be kept absolutely at rest, the foot of the bed elevated, abdominal binder firmly adjusted to abdomen, and fluidextractum ergotæ ʒj administered one hour after delivery.

If the loss of blood is sufficient to cause alarming symptoms in patient's general condition, prompt resort to diffusible cardiac stimulants is essential. Convalescence is always hastened by the administration of decinormal saline solution, fʒiv with spiritus frumenti fʒij by rectum every three hours. For the secondary anæmia following the loss of blood, iron and arsenic should be given in combination, such as:

R Liquoris acidi arsenosi, ..... f5 j;  
Tr. ferri chloridi, ..... f3 vj;  
Acidi hydrochlorici dilut., ..... f3 iv;  
Aq. menth. pip., ..... q. s. ad f3 vj.  
M. et Sig.: A dessertspoonful every four hours.

*Dr. E. William Ryon, of Wilmington, Del., observes:*

Post partum hæmorrhage is an acute condition, and must be met, in a majority of cases, by heroic measures. I will divide the treatment into prophylactic and active treatment.

*Prophylactic.*—If you get the history of a hæmophilic, give calcium chloride for three months prior to delivery, and be prepared for trouble. If patient is anæmic, run down, and poorly nourished, give iron manganese and tonics, advising fresh air, exercise, and nutritious diet.

If the patient is syphilitic, give the specific treatment all through pregnancy.

During the second stage of labor we should neither make a rapid delivery nor tedious one, unless special causes demand otherwise. Be careful to avoid great tension on the cord, looking out for cord around neck or body or limbs. Make a slow and careful delivery of the after birth by Credé's method. Don't give too much chloroform or ether.

2. *Active Treatment.*—Mechanical.—Grasp the uterus from the outside, as in Credé's method, and run a stream of hot water (120° F.) into the vagina.

If these measures do not control the hæmorrhage quick enough, place the hand into the uterus and clean it out, removing clots, secundines, etc., at the same time running our stream of hot water into the vagina. Remove hand from uterus during contraction and introduce our hot sterile water (120° F.) into the uterus. While working in the uterine cavity with the hand and injecting hot water, keep the other hand over the uterus on the abdomen, as in Credé's method. Most cases will be controlled by these measures, but if not, proceed to pack uterus and vagina with sterile gauze, removing it in about six hours. Ice, vinegar, and acetic acid are used as a styptic and (ice) to promote vascular contraction, but are not so good in general practice because of difficulty of being sure of their sterility.

While we are attending to these measures we have the pillows removed and the buttocks elevated or foot of bed raised. Also hot water bottles are placed around patient.

*Medicinal.*—We should try to give the medicinal

treatment at the same time as the mechanical. Give hypodermatically some reliable preparation of ergot. Also strychnine and atropine hypodermatically, being guided by patient's condition, giving boldly in urgent cases. Whiskey, camphor, aromatic spirits of ammonia, caffeine, etc., all have their place, but we usually use those stimulants we have at hand and give them hypodermatically, for we have little time to send out for medicine in most cases.

I have found enteroclysis and hypodermoclysis of normal salt solution valuable in nearly all cases. Venoclysis and transfusion are excellent in severe cases, where much blood has been lost and where it is possible to give them.

The after treatment consists of nutritious broths and meat juices and other easily assimilable foods; stimulants in most cases, carefully regulated, and replacement of lost blood where great amounts have been lost. The treatment is prescribed presuming that we have no great tears or trauma of parts. If the circular artery of cervix is torn or other vessels ruptured, keeping up the hæmorrhage in spite of our measures, we should at once proceed to close the tear by suturing.

Other cases of post partum hæmorrhage from exceeding exceptional causes are hardly frequent enough to call for discussion in this paper.

*Dr. Alfred T. Hawes, Lynn, Mass., says:*

The mortality of the third stage of labor is greater than that of the other two stages. Since hæmorrhage is probably the most common emergency of this stage, the physician should be fully prepared, before he enters the lying-in chamber, to meet this emergency with proper treatment.

The most important is the preventative treatment. If the possibility of hæmorrhage is kept constantly in mind, there are many things which can be done which will make its occurrence less likely. The labor should be carefully watched, and the patient should not be allowed to go too long without assistance. Exhaustion of the patient or of the uterus is productive of inertia of the uterine muscle.

During the second stage, there may be strong contractions of the uterus, but the patient cries out instead of using her abdominal muscles and bearing down. The contraction of the uterus, without the help of the abdominal muscles, may not advance the head and the condition may tend toward exhaustion. Relief may be obtained by the administration of an anæsthetic for a few moments, and as the patient comes out from the influence of the anæsthetic she will use her abdominal muscles to good advantage.

As soon as the shoulders are born, one hand should follow down the fundus and make sure that the uterus is contracting. While the physician is tying the cord and attending to the baby, an assistant should keep a firm hold on the fundus. After the baby is born, the quality which is required of the physician is "patience." Many cases of post partum hæmorrhage occur because the physician is in too great a hurry to get home.

Gentle pressure only should be made on the fundus before the placenta is born, and unless excessive bleeding occurs, which requires the immediate delivery of the placenta, there may be a wait of one

half hour before the placenta is delivered. Great care should be used in delivering the placenta, since retained portions of placenta and membranes are prolific sources of hæmorrhage.

After the placenta has been delivered, the fundus is to be held for one hour. The fingers are placed behind the fundus and the thumb in front, and gentle massage should be kept up to stimulate the uterine muscle. The vaginal entrance should be kept in view, and any increase in the quantity of blood will call for more vigorous manipulation of the fundus.

As soon as the uterus is empty, ergot should be administered. The tonic contraction of the uterus produced by ergot has four principal advantages: (1) It prevents post partum hæmorrhage; (2) it prevents after pains; (3) it diminishes the danger of air emboli; a uterus contracting and relaxing is apt to suck in air from the vagina; and (4) it diminishes the danger of sepsis; a firmly contracted uterus is less likely to become infected than a relaxed uterus filled with blood clots and retained lochia.

After the fundus has been held for one hour and the uterus has maintained good contraction, it is safe to apply the abdominal binder. This should be pinned from above downward in order to make downward pressure on the uterus. If pinned from below upward, it tends to lift the abdominal wall and the abdominal contents away from the uterus, thus allowing room for it to easily enlarge. The binder should be wide enough to come below the trochanters of the femur. If it does not do this, it always slips up and is useless for support.

As an additional security, a towel made into a roll may be placed over the fundus, underneath the abdominal pad. This roll should not be placed straight across the top of the fundus, as the fundus may be deflected to one side or the other and the pad would tend to push it farther to one side. The pad should be in the shape of a horseshoe and should embrace the fundus and sides of the uterus.

If these precautions to avoid hæmorrhage are carried out, the physician can wend his way homeward, feeling reasonably sure that he will not be called back in haste to attend the patient.

The different causes of post partum hæmorrhage need not be taken up here, as this paper has to do with treatment alone. Suffice it to say that any condition which favors bleeding should be avoided or removed if possible.

But whatever the underlying cause may be, the immediate cause of the hæmorrhage is "failure of the uterus to contract firmly."

The treatment, therefore, may be condensed into four words, *make the uterus contract*. How can it be done?

The most efficient stimulant to cause contraction of the uterus is mechanical irritation.

When an excessive amount of blood is seen issuing from the vagina, the fundus should immediately be grasped with the fingers behind and the thumb in front and kneaded vigorously.

If the excessive flow is not controlled by this method, the next procedure is to give an intrauterine douche of sterile water at a temperature of 110° F. If an intrauterine douche tube is not at hand, a syringe may effectively be brought about

by elevating the douchebag and allowing the stream of hot water to be injected forcibly against the cervix.

In cases in which these measures do not suffice to control the hæmorrhage, the operator carefully and quickly inserts his sterile right hand into the uterus. The movements of his knuckles on the walls of the uterus will soon produce firm contraction. At the same time, his left hand should knead the fundus and compress the abdominal aorta.

Such measures as carrying oil of turpentine, vinegar, ice, etc., into the uterus are not aseptic, to say the least, and are to be condemned. So, also, the various styptics which are sometimes recommended can control only capillary hæmorrhage and would have no effect on the hæmorrhage from one of the larger vessels in the uterine wall.

Let it be repeated that the best stimulant to contraction is mechanical irritation, and if hæmorrhage is not controlled by the hand in the uterus or tends to recur when the hand is withdrawn, the physician should proceed without further delay to pack the uterus with gauze.

A jar of sterilized gauze should have been previously prepared, but if it is not at hand, a strip three inches wide may be torn from a clean sheet, placed in a dish of water and boiled for twenty minutes and may then be used as packing for the uterus.

The instruments needed to pack the uterus are the volcella forceps and the uterine dressing forceps. The ordinary uterine dressing forceps, on account of its sharp point, is an element of danger from the fact that the point may be pushed through the fundus. Forceps with blunt points are much safer. There is very little danger that the cervix will contract so as not to admit the blunt forceps, and they are far safer than the pointed ones so generally used.

After the uterus has been packed, the abdominal binder and the pad over the fundus should be firmly applied. The uterine packing should not be left more than six or eight hours, as it very quickly becomes foul. When it is removed, another packing should be ready to replace it if necessary.

After a severe hæmorrhage, the patient may show signs of the loss of blood, and treatment for this condition should be at once instituted. The pillows should be removed and the foot of the bed elevated. The patient should be covered with hot blankets and surrounded with hot water bottles. While the uterus is packed, there is no danger that the external heat will increase the hæmorrhage.

If the condition of the patient demands it, normal salt solution should be administered. The general practitioner, without skilled assistants, is sometimes at a loss to know how to make sterile salt solution, but by keeping in mind the following points, he may obtain all he needs by using the utensils found in almost every household: 1. Scrub the inside of a double boiler with sand soap and rinse it in clean water. 2. Pour into it two quarts of hot water from the teakettle and add four small teaspoonfuls of table salt. Dissolve the salt thoroughly. Add a little more water, to allow for evaporation, so that after boiling for twenty minutes the quantity will be two quarts. 3. In another dish place a handful of absorbent cotton and a tin funnel, which is usually found in every kitchen. This is to filter the salt solu-

tion after it is boiled. The rubber douchebag and the salt solution needle are to be wrapped in a towel and placed in the dish to boil. 4. After boiling for twenty minutes, the salt solution should be filtered through the sterilized cotton in the funnel into the douchebag, and is then ready for use. If it is too hot, it may be cooled by letting cold water run over the outside of the bag.

The salt solution may then be given in sufficient quantity under the breast or may be injected slowly into the rectum.

The rate and quality of the pulse should be carefully watched and stimulation given as needed. The drugs which are of most value in the condition following hæmorrhage are adrenalin, digitalin, and strychnine.

The severer forms of post partum hæmorrhage are fortunately rare, and with the exception of cases in which there are pathological changes in the blood, the hæmorrhage can be controlled. But it is necessary for the physician to be constantly on his guard and to be prepared to meet the emergency with prompt treatment.

*Dr. S. A. Agatston, of New York, says:*

Prophylaxis is important. Attend to general health during pregnancy by improving appetite, if necessary urging the consumption of plenty of good food, exercise and tonics if required. If labor is prolonged, find out cause and remove it possible. Thus, make sure that the bladder and rectum are evacuated. Examine carefully to ascertain if presentation is normal, and if not, correct same according to the requirements of the case. If the uterus simply shows tendency to weakness and relaxation, give strychnine sulphate, gr. 1/30. If the patient is exhausted, it is a good plan to give chloral hydrate 15 gr., as we often find that after a good rest the uterus contracts with renewed vigor. During the birth of the child order the nurse to follow the fundus and continue to hold it after the child is born. Better than Credé's method of expression of placenta after fifteen minutes is to gently massage the uterus until the latter empties itself after thorough separation. It takes longer, but is safer. Examine the placenta carefully to ascertain whether all the membranes came away. If, after taking all the precautions, there still is hæmorrhage with relaxation of the uterus, massage the fundus vigorously and express all the clots, and if necessary introduce your hand into the uterine cavity and remove them, incidentally feeling for a possible placenta succenturiata. If hæmorrhage still continues, give hot douche (water at 116° to 120° F.) with 2 to 5 per cent. acetic acid. As a final resort pack the uterus with sterile gauze, or in the absence of the latter, with strips of clean linen or clean towels. The packing should not remain in longer than twenty-four hours. If the uterus is not relaxed and hæmorrhage is present, it is due to the laceration of the cervix, and it is necessary then to repair the tear, taking good care not to close the os too much, as that would cause retention of lochia. If hæmorrhage has been excessive, we may have to make use of saline infusion, hypodermic, and saline enemata. Administer fluid extract of ergot.

## Therapeutical Notes.

**Vertigo of Gastric Origin** is treated by Becker (*Merck's Archives*, x, 1) by regulating the diet, putting some patients on an exclusive milk diet, and encouraging them not to worry. While he does not deem medication of great importance, he advises the administration of a simple tonic bitter before meals, *e. g.*, ten drops of the tincture of nux vomica in water, and after eating, at intervals of one hour, the following prescription:

B Diluted hydrochloric acid, ..... M ℥ss  
Powdered pepsin, ..... gr. v  
Sodium bromide, ..... gr. x  
Peppermint water, ad ..... ℥ss

M.

As a laxative he prescribes one teaspoonful of sodium phosphate to be taken in a glassful of hot water before breakfast.

**The Use of Sea Water in Medicine.**—In a recent number of the *Répertoire de pharmacie* (*British Medical Journal*) Carles gives an interesting account of the use of sea water in medicine. In addition to common salt sea water contains many important mineral substances, the total solid matter amounting to 3.2 to 3.8 per cent. Some of these substances are present only to an infinitesimal extent, but in biology the value of a substance is not necessarily dependent upon its actual size or quantity. It has been shown that various marine plants have the power of extracting from sea water minute quantities of compounds of iodine, bromine, arsenic, boron, manganese, lithium, fluorine, rubidium, cesium, and other elements. Hence it was not unreasonable to suppose that the higher animals might derive benefit from the assimilation of even minute traces of these physiologically active substances. The employment of sea water as a remedial agent dates back to the time of Hippocrates, and modern physiological investigations have led to its reintroduction into medicine. Thus it has been shown that if a portion of the blood serum of a dog be replaced by an artificial serum the most suitable serum for the purpose is sea water, isotonic with the natural serum. Sea water has been given by the mouth and by injection with good results in cases of dyspepsia, loss of appetite, and tuberculosis. In general the appetite was improved and strength was rapidly regained. In order to obtain the best and most immediate results it is necessary to observe certain precautions. The sea water must be natural, as it is impossible to imitate so complex a liquid. Indeed, it has been proved that sea salt, when redissolved in distilled water, lacks some of the properties of natural sea water, exerting a tonic action upon a dog when injected subcutaneously. It must be freshly collected, as it loses carbon dioxide on standing, with precipitation of some of its salts. It should be taken from the open sea remote from rivers and other sources of pollution. It should be sterilized by filtration, as heat dissociates the bicarbonates and destroys the natural equilibrium of the liquid. When required for subcutaneous injection it should be diluted with water to the same concentration as normal blood serum. Distilled water is not suitable as a

diluent, as it sometimes causes pain. It is better to dilute the sea water with natural potable water in the proportion of 2 parts to 5. In conclusion, Carles points out that this method of treatment is not invariably suitable, and that it rests with clinical experience to indicate the cases in which it may advantageously be employed.

**Some Applications of Resorcin.**—The value of resorcin in the treatment of certain dermatoses receives appreciative consideration in an article published in *La Presse médicale* for January 11th. Being a phenol, isomeric with pyrocatechin and hydroquinone, having the chemical formula  $C_6H_4(OH)_2$ , its internal use has been abandoned. Like aristol, chrysarobin, [pyrogallol], ichthyol, and sulphur, resorcin acts as a reducing agent by uniting with the oxygen of the tissues with which it is brought into contact. It exerts a keratolytic action on the cutaneous surface and hardens the mucosum, thus hastening desquamation. If the action is prolonged an alterant effect is produced on the cells lying below the rete mucosum, and blistering and secondary exfoliation may ensue. It is this property possessed by it on which is based the keratolytic exfoliative treatment of Unna. In parasitic diseases of the skin resorcin cures (1) by a mechanical removal of the disease germs; (2) by a direct antiseptic action, and (3) indirectly by its power of depriving aerobic germs of the oxygen necessary for their development. In cases of follicular eczema, seborrhoea of the scalp, pityriasis, etc., the following ointment is applied at night and washed off with soap and water in the morning:

B Resorcin, ..... gr. x to gr. xv;  
Wool fat, ..... 5v.

M.

Sabouraud's application is more complex, being composed as follows:

B Resorcin, ..... gr. x to gr. xv;  
Ichthyol, ..... .ââ gr. xv;  
Precipitated sulphur, }  
Oil of cade, ..... gr. lxxv;  
Wool fat, ..... 3viis.

M.

Unna's exfoliative resorcin paste has the following composition:

B Resorcin, ..... gr. 5v;  
Zinc oxide, ..... gr. lxxv;  
Precipitated silica, ..... gr. xv;  
Benzoinated lard, ..... 3viii.

M.

The paste is allowed to remain in contact with the skin for a few minutes only.

Another property possessed by reducing agents like resorcin when applied in mild strengths for any length of time is to contract and atrophy the vessels of the derma, especially if it is made to penetrate the tissue, which is made possible by using glycerin as a vehicle and abrading the skin. Advantage of this is taken in the treatment of nonneoplastic warty growths in the deep folds of integument caused by continued local irritation, as for instance the fungous excrescences that develop in the labia pudendi, prepuce, scrotum, perinæum, nipples, umbilicus, etc. In these cases the best method of treatment is to scrape the parts with a bistoury or curette, and cut away any protruding growths, and afterwards apply for two or three days a glycerin solution of resorcin of the following strength:

B Resorcin, ..... 5iiss to 5iii;  
Glycerin, ..... 5iij.

M. Sig.: External use.

The resorcin may be also applied as a powder in the following combination:

B Resorcin, ..... gr. xv;  
Bismuth subnitrate, ..... gr. lxxv;  
Powdered talcum, ..... 3x.

M.

A solution of resorcin in flexible collodion is useful for application to certain parts of the body, the following proportions being recommended:

B Resorcin, ..... gr. xxx;  
Flexible collodion, ..... 5v.

M. Sig.: External use.

**The Use of Iodine-Formic Acid Solution in the Treatment of Phthisis.**—In a paper contributed to the *Journal of the American Medical Association* for February 1st, Stern describes the method of preparation and mode of administration of the iodine-formic acid solution which he uses in the treatment of chronic ulcerative phthisis. The solution is made according to the following process:

A. To make the "mother preparation" (10 per cent. glycerioiodoformic acid) take:

Iodine, q. s. (an excess, formic acid, taking up a certain quantity only).  
Formic acid, 40 per cent. (sp. gr. 1.200), ..... 25 c.c.;  
Glycerin, ..... q. s. ad. 100 c.c.

The dissolving process must ensue in the cold formic acid and may be hastened by agitation.

B. To make 1 per cent. iodoformic acid, take:

Glycerioiodoformic acid (10 per cent.), ..... 10 c.c.;  
Distilled water, ..... 90 c.c.

C. To make glycerioiodoformic acid dil. (for internal administration) take:

Glycerioiodoformic acid (10 per cent.), ..... 10 c.c.;  
Glycerin, ..... 90 c.c.;  
Distilled water, ..... 1,400 c.c.

The iodine formic acid solutions should be kept in dark colored glass stoppered bottles and scrupulous care should be exercised to prevent any contamination of the solutions, especially with organic matter (dust).

The dose of the diluted solution (C) given internally is one tablespoonful, representing one c.c. of solution B.

For intramuscular injection the one per cent. solution of iodoformic acid is exclusively employed, 10 drops being injected, half into the left and half into the right interscapular muscle bundles. This dose is repeated for three or four days, after which the dose is increased to twenty drops for a similar period. Following this the dose is increased to 30 drops, injecting it every other day for two or three weeks. A specially constructed syringe is used, the barrel and piston being of glass. The barrel should be graduated and, if possible, have a capacity of three cubic centimetres. Excepting the needle, and possibly the finger rests, nothing but glass should enter into the construction of the syringe. The piston must be ground to fit snugly into the barrel. The injection site is prepared by cleaning with ether and placing a few drops of the iodine formic acid on it. Ether in sufficient quantity exerts also a local anæsthetic effect, which property is of decided value in intramuscular injections of any solution. The needle, of course, has to be inserted from above downward and should meet the body (seen from above) at an angle of about 75 degrees.

Entered at the Post Office at New York and admitted for transportation through the mail as second class matter.

NEW YORK, SATURDAY, FEBRUARY 8, 1908.

## A NATIONAL DISGRACE.

There are some articles which we do not yet produce in the United States of a degree of excellence equal to that of similar products made elsewhere; it may be that there are a few in the production of which we never shall make a very close approach to foreign competitors. For example, our textile fabrics, save those made of cotton, are well known to be inferior; we must still resort to older countries for fine silks, linens, flannels, and the general run of woollen goods. No harm can come from our frankly acknowledging this.

On the other hand, we make some things that are superior to those made in other countries, and we turn out many articles that are almost if not quite as good as can be found anywhere in the world. This was amusingly illustrated by something that occurred recently in New York. A party of gentlemen had been dining in a French restaurant and one of them remarked that it was many years since he had tasted sparkling Catawba, but that his memory of that American wine was pleasant. It was suggested that Catawba was probably to be had in a neighboring café kept by a producer of native wines. Thereupon the company adjourned to that resort and called for a bottle of sparkling Catawba. When the wine was brought it was found to bear the label "Moselle." It was remarked to the waiter that he had misunderstood the order. "Oh, no," said he, "this is Catawba, all right." It was found to be an excellent wine, but probably it was difficult

to sell it to advantage under its own name, so pervading is the snobbery which insists that everything fine must have been imported.

Another incident of like import was the recent arrival at the port of New York of several thousand empty cheese boxes from France, with their French labels, designed as receptacles of "Camembert" cheese made in the State of New York, to be employed to deceive the public. We have nothing to say against such cheese itself; it is of the same type as the French Camembert, and perhaps it would be judged by most of us to be quite as good as the same style of cheese made in France. It might even be allowable to call it Camembert, but it could not honestly be marketed under that name without some qualifying designation to show that it was of American make. To represent it as having been made in France would be fraudulent.

But it is not with the element of commercial fraud that we are here concerning ourselves. The worst of the whole misbranding business, apart from the substitution of injurious for wholesome products, is its inevitable bolstering up of the disgraceful feeling that we Americans are not justified in holding any of our home productions in the highest esteem. That affectation needs to be rooted out, and in the long run the process will be powerfully aided by recent national legislation, but State legislation, not only in New York, but elsewhere also, is needed to supplement that enacted by Congress. Let us freely admit our shortcomings, but let us at least give our products the chance to win under their own names whatever approval they may be found to deserve.

## FEED THE HOSPITAL PATIENT.

Our abhorrence of the slop diet system of treating acute disease must be well known to our readers, for we have harped on it persistently. The prescription of low diet stands on no substantial basis of clinical observation; it is simply a feature, and an unpleasantly prominent one, of the traditional notion—almost ineradicable, it sometimes seems—that a sick man can hardly be helped except by making him as miserable as possible. The old plan was to rob him of as much blood as he could give up without at the same time giving up the ghost, salivating him with enormous doses of calomel, nauseating him with antimony, and forbidding him to assuage his sufferings by drinking water, at the same time seeing well to it that he should get the minimum of nourishment. The practice is not so old that many of us do not remember its invariable enforcement. Fortunately, all these ridiculous measures have been relinquished save the one relic of starvation. But this is founded on a sincere if mistaken purpose.

to benefit the patient, and it is not our present intention to speak further of it. What we have to say now concerns a policy that takes little if any account of the patient's welfare, one of pure niggardliness.

In almost all our hospitals the food provided for the patients is abominably repulsive. It is furnished in abundance, and we do not doubt that it is for the most part nutritious. With a trifling increase of expense it might be made appetizing, and nobody will deny that a sick man's inclination to take food ought to be encouraged rather than smothered. With what feelings of repugnance must such a man spoon into his mouth a lukewarm decoction of turnips, waste his already enfeebled energy in chewing a leathery steak, or seek to retrieve from his plate a portion of custard that seems bent on floating away in the whey that oozes out from it! We are not advocating green turtle soup, stewed terrapin, *pâté de foie gras*, plum pudding, and burgundy for the hospital patient's dinner, but we do insist that the plain but good material furnished ought to be prepared in an attractive form.

As regards our hospitals, cookery seems to be a lost art—at all events one that is ignored. Proper attention to the marketing will procure unexcelled roasting pieces of beef at a moderate cost, and the slices ought to come to the wards in better condition than that in which they are ordinarily to be obtained in expensive restaurants, for the patients all dine at a fixed hour, so that the meat has not to be kept warm for an indefinite length of time, whereby the life is steamed out of it. It will not do to say that the patient comes from the slums and has never been used to good living; he is sick, and it would be the part of wisdom to induce him to eat heartily during his convalescence, so as to shorten his necessary stay in the hospital. Moreover, the story he would tell on returning to his old haunts would go far toward dissipating the dislike of the poor to being sent to Bellevue or "the island."

#### THE METALLIC FERMENTS IN THERAPEUTICS.

As is well known, Professor Albert Robin, of Paris, has experimented largely during the last five or six years with certain preparations of the heavy metals, gold, silver, platinum, and palladium. These are apparently in solution, but actually suspended in a state of minute subdivision. Examined with a microscope in the usual way, in the preparations employed, the separate metallic particles are invisible, but if examined by reflected light with the ultra-microscope, they become clearly evident as minute bodies less than one two millionth of an inch in diameter, and endowed with an extremely active

Brunonian movement. Their method of preparation, their physiological effects, and their therapeutic uses are fully considered in Robin's monograph (*Les Ferments métalliques*, Paris, 1907). Briefly Robin passes an electric current (D. C. 110 v, 3 a) through chemically pure water, the terminals of the selected metal being sufficiently near to permit the passage of a spark. As the sparks pass the water gradually colors, finally becoming violet in the case of gold or black if platinum terminals are used.

In carrying out physiological experiments with the various "solutions" Robin noticed that there was a striking resemblance between their effects and those produced by certain ferments of organic origin, notably an increase of metabolic activity. And one very remarkable effect of the administration of these ferments was the great increase of urinary indican, both in normal subjects and in cases of disease. We can hardly conceive of this being due to any increase of intestinal indol, and we are forced to conclude that the substances must possess some special depurative function in connection with this body.

Therapeutically, Robin employs his solutions, if they may be called such, either in intravenous injections of 5 c.c. or deep intramuscular injections of 10 c.c. The author's most brilliant results have been in connection with pneumonia, acute articular rheumatism, and septicæmia. The immediate effects were prompt defervescence and rapid recovery. In chronic affections beneficial results were not so evident.

#### THE EPILEPTIC VOICE SIGN.

The oft repeated declaration that Hippocrates nearly if not quite completed the clinical description of epilepsy has not wholly prevented further efforts in this direction. Now and then we note that not unimportant advances are made to a clearer understanding of this strange disease. It may not seem so peculiar as would at first appear that no study has ever been made of the epileptic voice, when one realizes that only during the past few years has it been possible to study the normal voice carefully by anything like a scientific method. Our thanks for this latter consummation are due in greater part to the Carnegie Institution and to Dr. E. W. Scripture in particular. By what is known as the air puff method Scripture has found it possible to study the voice accurately in both health and disease.

Equipped with this method, Clark, Scripture, and Pierce have undertaken to study the characteristics of the epileptic voice.<sup>1</sup> Many clinicians have noted

<sup>1</sup>Scripture and Clark, *Researches on the Epileptic Voice*, Proceedings of the New York Neurological Society, November 12, 1907.

the monotonous, breathy tone of the epileptic voice without being able to catch exactly another elusive feature which Clark and Scripture have analyzed. The method is so novel that it deserves comment. Briefly stated, it is as follows: The patient speaks into a mouthpiece that covers his mouth rather tightly. The mouthpiece is connected with a small recording capsule that registers the vibrations on a rapidly revolving smoked drum or kymograph. The character of the resulting curve can be illustrated by an example. In the records of the words "most-ly, at night," with the sounds like (m), (o), (l), (y) the larynx vibrates. These vibrations produce wavy lines in the record. A long wave is produced by a slow vibration, a short wave by a quick one. Slow vibrations correspond to low pitch, quick ones to high pitch. Each wave of the record is measured and the pitch is calculated. For example, the first six vibrations of (m) measure 1.3, 1.2, 1.1, 1.0, 1.0, 1.2 mm. The calculations give a pitch of 110, 119, 130, 143, 143, 119 vibrations to the second. That is, the first vibration corresponds to a tone of 110 vibrations, the second to a somewhat higher tone, the third gives a still higher one. A line connecting the top of the ordinates is termed the "melody plot." Every vowel in normal speech has a rising and falling melody. In the epileptic voice the vowels run along on even tones. It is a form of "plateau speech," as they have termed it.

The authors say that, when once explained, the epileptic voice defect may be recognized at once. In an analysis of cases one can, by a little practice, they maintain, diagnosticate the disorder by the voice alone. The authors demonstrated the voice signs and showed a record of diagnosis in 75 per cent. of a trial test in 100 cases. There appears to be no parallel in any other nervous disorder tested by the authors. Many of the cases were entirely free from the effects of bromides. All grades of severity of epilepsy have been under study. It would appear that the voice sign is dependent upon the brain deterioration of the epileptic, upon which the mental stigmata, as shown in slowness, awkwardness, and dementia, also rest. The voice sign ought to be of diagnostic value, and is worthy of statistical study in the many State colonies and hospitals for epileptics.

#### THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

The one hundred and second annual meeting, held in Albany last week, marked the continued usefulness of this organization. The election of Dr. Trudeau to the presidency for the coming year augurs well for a year of efficient work. Dr.

Trudeau is himself an organizer of conspicuous capacity, and his professional renown in connection with the present campaign against tuberculous disease will make his presidency distinguished. The movement in favor of holding the annual meetings in each of four large cities of the State in turn was favored by the committee to which it had been referred. From every point of view except that of the tradition which credits the legislature with a sort of paternal requirement that all the meetings shall be held in Albany, and during its own session, the project seems to us highly worthy of consummation. Surely there is much to be learned in Buffalo, Rochester, and other large towns of the State of New York, and the accommodations in them are ample.

#### THE "MELODY CURE" FOR STUTTERING.

Some weeks ago Dr. E. W. Scripture, of Columbia University, explained before one of the medical societies of New York a method of curing stuttering by training the afflicted person to put a varying intonation into his speech—in other words, to sing it. He seems to have developed and systematized this procedure, but we presume that he would be the last to allege that he had made a "discovery" of the device, as some of the newspapers declare, for the principle itself was long ago put into practice, though the use of it may have been known to but few persons. It certainly appears to offer a distinct prospect of overcoming an embarrassing defect.

#### ABBREVIATIONS OF PHARMACOPEIAL NAMES.

In the course of an address recently delivered before the New York College of Pharmacy, Professor J. P. Remington, of Philadelphia, chairman of the Revision Committee of the *United States Pharmacopæia*, made an incidental reference to the question of abbreviations of pharmacopeial names which was in effect a defense of the lengthy titles which have been given in the pharmacopæia to some of the newer remedies. The professor said that, as a matter of fact, the average prescriber never used the full name of a drug, but prescribed it, and soon came to know it by some abbreviation, "acetphen" being the abbreviation which he used for acetaminophen, while hexamethylenamine became in his memory and in his prescription merely "hex." It seems to us that the common use of such an abbreviation may induce the committee to refuse from adding to the pharmacopæia any other name the name of which begins with "hex."

## GENERAL ANÆSTHESIA WITH SIMULTANEOUS ARTIFICIAL SEQUESTRATION OF A PORTION OF THE CIRCULATION.

In a recent issue of this journal we adverted editorially to the fact that this procedure, advocated a few months since by Professor Klapp, of Berlin, had been proposed and practically applied by a New York neurologist, Dr. J. Leonard Corning, twenty years before. Corning's papers, as then stated, were published in the *New York Medical Journal* for October 22 and December 24, 1887. It is a pleasure to note that since the appearance of our editorial and after reading Corning's papers, Professor Klapp has published a brief article in the *Therapie der Gegenwart* for January, 1908, Heft i, page 47, in which he unreservedly gives Corning entire credit for the priority of the discovery.

## A UNIFORM CATHETER SCALE.

The American Surgical Trade Association has published cards showing the standard catheter scale as prepared by a committee of that organization. These cards give the sizes in millimetres and also give the arbitrary numbers by which these sizes are indicated. We congratulate the association upon its excellent work in the preparation of these cards, which will undoubtedly be welcomed by physicians generally, offering a relief from the uncertainty which has existed hitherto regarding the method of designating the sizes in catheters. We understand that dealers in surgical instruments will be prepared to furnish these cards to physicians on application.

## Obituary.

CARL VON VOIT, M. D.,  
of Munich, Germany.

The death of Dr. Carl von Voit, the distinguished physiologist, is reported from Munich, Germany. Born in Amberg, Bavaria, on October 31, 1831, he studied medicine at the universities of Würzburg, Göttingen, and Munich, and was graduated in 1854. Two years later he became assistant to von Bischoff at the physiological institute. Having been admitted as Privatdozent to the medical faculty of his alma mater in 1857, he was appointed assistant professor in 1860, and in 1863 was elected professor of physiology, when von Bischoff resigned from this chair, reserving for himself the department of anatomy. Thus von Voit had held the professorship of physiology at Munich for nearly forty-five years. He has been one of the leaders of this branch of medical science in Germany. In 1865 he founded, with von Pettenkofer and von Buhl the *Zeitschrift für Biologie*.

The writings of von Voit treat especially of the theory of general metabolism and nutrition, and his theories and teachings have laid the foundation for the modern conception of the physiology of metabolism.

Although the recipient of many high honors, Dr. von Voit always remained unassuming, quiet, and retired. He was equally beloved by his colleagues and by his pupils, to whom he was not only a teacher, but a friend and adviser. With von Voit dies the last member of that medical faculty of Munich which made the Bavarian capital so celebrated, not only in Germany, but also abroad.

WILLIAM STRATFORD, M. D.,  
of New York.

Dr. Stratford died on Friday, January 24th, at the age of sixty-four years. He was a graduate of the Medical Department of the University of the City of New York of the class of 1876. He practised medicine for a number of years, but subsequently concentrated his attention on natural history, of which he was the professor in the College of the City of New York at the time of his death. He was active also in the athletic affairs of the college. He was an attractive gentleman, and those who knew him well were exceedingly fond of him.

## News Items.

**Changes of Address.**—Dr. J. B. Rankin, to 177 Onderdonk avenue, Ridgewood, Brooklyn, N. Y.

**The Wisconsin State Board of Health and Vital Statistics** held its annual meeting on January 29th, and re-elected Dr. William F. Whyte, of Watertown, president, and Dr. C. A. Harper, secretary.

**Maryland Tuberculosis Sanatorium.**—Senator Moore has introduced into the Maryland State Legislature a bill appropriating \$175,000 for the Maryland Tuberculosis Sanatorium. Two years ago an appropriation was made, but this sum has been exhausted.

**The Sixth Lecture in the Harvey Society Course** will be given by Professor Joseph Jastrow, of the University of Wisconsin, at the New York Academy of Medicine on Saturday, February 8th, at 8:30 p. m. The subject of the lecture is Subconsciousness.

**Surgeons with Experience for Ambulance Duty.**—A bill has been introduced into the State Legislature by Senator Sohmer which provides that no surgeon in any hospital in the city of New York shall be called upon for ambulance duty unless he shall have served at least six months in a hospital.

**Kings County Medical Society.**—At a recent meeting of this society, the following officers were elected to serve for the year 1908: Dr. Onslow A. Gordon, president; Dr. J. M. Van Cott, vice president; Dr. Henry G. Webster, secretary; Dr. John R. Stivers, treasurer; Dr. James R. Warbase, director of the library.

**Kentucky Midland Medical Society.**—At the annual meeting of this society, held recently in Midway, Ky., the following officers were elected for the ensuing year: President, Dr. Neville M. Garrett, of Frankfort; vice president, Dr. Josephus Martin, of Cynthia; secretary and treasurer, Dr. George P. Sprague, of Lexington.

**Syracuse, N. Y., Academy of Medicine.**—At a meeting of this academy held on Tuesday evening, February 4th, the programme included the following papers: A Case of Maldevelopment of the Uterus and Vagina, by Dr. M. D. Bristol; Caloric Value in Infant Feeding, by Dr. A. C. Mercer; and Appendicectomy, with Description of a Method, by Dr. T. L. Deavor.

**Diphtheria at the Rahway Reformatory.**—According to a report submitted to Dr. George B. Wright, Commissioner of Charities and Corrections, there is an epidemic of diphtheria at the reformatory at Rahway, N. J. On February 3d there were ninety-nine cases in the institution, an increase of fifty cases in three days.

**Richmond, Va., Academy of Medicine and Surgery.**—At a meeting of this academy, held on January 28th, Dr. E. C. Levy read a paper on the Importance of the Cooperation of the Medical Professional in Municipal Public Health Work. Dr. A. W. Freeman read a paper on Preliminary Studies of Typhoid Fever in Richmond.

**A New Hospital for New York.**—A bill has been introduced into the Legislature authorizing the Board of Estimate and Apportionment of the City of New York to appropriate \$1,000,000 for the erection of a new public hospital in New York. The bill also provides for the appointment by the Mayor of a commission to obtain the site and prepare plans for the new hospital.

**Rochester, N. Y., Academy of Medicine.**—The regular meeting of the Section in Obstetrics, Gynecology, and Pædiatrics was held on Wednesday evening, February 5th. The paper of the evening, entitled *The Clinical Significance of Glycosuria During Pregnancy*, was read by Dr. J. Whitridge Williams, professor of obstetrics at Johns Hopkins University Medical College.

**Buffalo Academy of Medicine.**—A stated meeting of this academy was held on Tuesday evening, February 4th. The programme of the evening, which was furnished by the Section in Surgery, included a paper by Dr. Edward L. Keyes, Jr., of New York, on the Treatment of Acute Prostatitis and Allied Complications of Gonorrhœa, and a paper by Dr. Vertner Kenerson on Inguinal Hernia.

**In Memory of Dr. Senn.**—Memorial services in honor of the late Dr. Senn were held in Chicago on Sunday, February 2d, under the auspices of Rush Medical College, the Northwestern University Medical School, the College of Physicians and Surgeons, Chicago Medical Society, Chicago Surgeons' Association, and the Nicholas Senn Club. Dr. Edmund James James, of the University of Illinois, presided.

**Scientific Society Meetings in Philadelphia for the Week Ending February 15, 1908.**—*Monday, February 10th.*—Section in General Medicine, College of Physicians; Wills Hospital Ophthalmic Society. *Tuesday, February 11th.* Philadelphia Pædiatric Society; Botanical Section, Academy of Natural Sciences. *Wednesday, February 12th.* Philadelphia County Medical Society. *Thursday, February 13th.* Pathological Society; Section Meeting, Franklin Institute. *Friday, February 14th.* West Branch, Philadelphia County Medical Society.

**Elmira, N. Y., Academy of Medicine.**—At the regular meeting of this academy, which was held on Wednesday evening, February 5th, the following papers were read: *The Chemical Purity of Drugs*, by Dr. S. E. Palmer, of Elmira; *Backward Displacement, with Abortion*, by Dr. Elliott T. Bush, of Horseheads; *Report of a Case*, by Dr. Alfred J. Westlake, of Elmira. The officers of the academy are as follows: President, Dr. Ross G. Loop; vice president, Dr. Alfred J. Westlake; treasurer, Dr. Charles G. R. Jennings; and secretary, Dr. Frank L. Christian.

**The Obstetrical Society of Philadelphia.**—At a stated meeting of this society, held on Thursday evening, February 6th, Dr. Collin Foulkrod read a paper on the Toxæmia of Pregnancy; Dr. John B. Shober reported a case of Nephroureterectomy for Tuberculosis, Hysterectomy, Appendectomy; Dr. Theodore A. Erck reported a case of Nephroureterectomy and a case of Resection of the Cecum for Tuberculosis; and Dr. E. A. Schumann read a paper on Tuberculosis of the Uterus with Pyometra. The discussion was opened by Dr. Charles P. Noble, Dr. Barton C. Hirst, and Dr. Wilmer Krusen.

**The Massachusetts Association of Boards of Health.**—The annual meeting in Boston on January 30th, and elected officers for the ensuing year as follows: President, Dr. Henry P. Walcott, president of the State Board of Health; first vice president, Dr. S. H. Durum, of the Boston Board of Health; second vice president, Dr. Charles V. Chapin, of the Providence, R. I., Board of Health; secretary, Dr. James C. Coffey, of Worcester; and treasurer, Dr. James B. Fields, of Lowell. Rhode Island, having no State association of its own, has joined the Massachusetts association.

**Nassau Hospital.**—It was reported recently that the Nassau County Hospital, Mineola, L. I., would close on account of financial difficulties, but at a meeting of the Executive Committee of the Nassau Hospital Association it was decided to keep the institution open. The committee has a plan under consideration whereby \$120,000 can be raised by bed endowment, and a large sum has already been sent in. If, however, the committee finds it impossible to continue the operation of the hospital on the new basis, it is said that the Catholic Diocese of Long Island may take over the property, assuming the mortgage, the endowment, and all the liabilities.

**American Society of Sanitary and Moral Prophylaxis.**—A regular meeting of this society will be held at the New York Academy of Medicine on Thursday, February 13th, at 3:30 p. m., under the auspices of the Committee on Education. Dr. G. Stanley Hall, president of Clark University, will read a paper on the Needs and Methods of Educating Young People in the Hygiene of Sex, and Mr. Frederick S. Curtis, principal of the Curtis School for Boys, will read a paper on *Several Years' Practical Experience in Educating Boys in the Hygiene of Sex*. Among those who will take part in the discussion are Professor Thomas L. Balliet, Professor Seligman, and Dr. J. P. Warbasse.

**Medical Society of the Missouri Valley.**—The semi-annual meeting of this society will be held in Lincoln, Neb., on March 19th and 20th, and the programme is now open for contributions. Titles should be sent to the secretary early, as all papers will appear on the programme in the order in which they are received, and the number of papers is limited to twenty-five. The officers of the society are: President, Dr. O. Beverley Campbell, of St. Joseph, Mo.; first vice president, Dr. W. F. Milroy, of Omaha, Neb.; second vice president, Dr. C. O. Thienhaus, of Milwaukee, Wis.; secretary, Dr. Charles Wood Fassett, of St. Joseph, Mo.; treasurer, Dr. Donald McRae, of Council Bluffs, Ia.

**City and Village Sanatoria in Illinois.**—The bill providing for the establishment of sanatoria for tuberculous patients in cities and villages of Illinois, which was known in the Illinois Legislature as Senate Bill No. 598, has become a law, as we are informed by a telegram from Dr. J. A. Egan, secretary of the Illinois State Board of Health. The bill provides that any municipal government may levy a tax not to exceed four mills on the dollar annually, the sum collected to be known as the Tuberculosis Sanatorium Fund, which is to be used for the establishment and maintenance of public sanatoria for the benefit of such of the inhabitants of the city or village as may be afflicted with tuberculosis.

**The Mortality of Chicago.**—According to the report of the Department of Health for the week ending January 18, 1908, there were during the week 715 deaths from all causes, as compared with 638 for the corresponding week in 1907. The annual death rate was 17.21 in 1,000 of population. The principal causes of death were: Apoplexy, 8; Bright's disease, 45; bronchitis, 28; consumption, 71; cancer, 29; convulsions, 3; diphtheria, 15; heart diseases, 51; influenza, 56; intestinal diseases, acute, 28; measles, 2; nervous diseases, 27; pneumonia, 124; scarlet fever, 15; suicide, 14; typhoid fever, 9; violence, other than suicide, 22; whooping cough, 2; all other causes, 166.

For the week ending January 25th there were 687 deaths from all causes, as compared with 735 for the corresponding week in 1907. The annual death rate in 1,000 of population was 16.54. The principal causes of death were: Apoplexy, 8; Bright's disease, 37; bronchitis, 22; consumption, 81; cancer, 25; convulsions, 8; diphtheria, 7; heart disease, 53; influenza, 49; intestinal diseases, acute, 35; nervous diseases, 28; pneumonia, 132; scarlet fever, 12; suicide, 9; typhoid fever, 9; violence, other than suicide, 23; whooping cough, 2; all other causes, 147.

**Popular Lectures at Johns Hopkins University.**—The committee on public education of the Medical and Chirurgical Faculty of Maryland have made arrangements for a course of lectures to be delivered at Johns Hopkins University on Saturday evenings during February and March, with the exception of February 2d. The lecture on February 1st was given by Dr. Charles O'Donovan, of the Board of Health in Town and County, and on Saturday evening, February 8th, Dr. Hyram Woodhull, will deliver an address on *Eight and School Life*. The remainder of the series is as follows: February 12th, *Tuberculosis*, by Dr. William

S. Thayer; February 20th, Modern School Life and its Effect upon Health, by Dr. Warren H. Buckler; March 7th, Preventive Medicine, by Dr. William H. Welch; March 14th, Milk and its Relation to Disease, by Dr. John Ruhrah; March 21st, What the City Does in the Prevention of Disease, by Dr. C. Hampson Jones; March 28th, Public Water Supplies, by Dr. Marshall Price.

**The Health of Philadelphia.**—During the week ending January 11, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Typhoid fever, 104 cases, 14 deaths; scarlet fever, 55 cases, 0 deaths; chickenpox, 62 cases, 0 deaths; diphtheria, 112 cases, 7 deaths; cerebrospinal meningitis, 6 cases, 2 deaths; measles, 88 cases, 4 deaths; whooping cough, 17 cases, 0 deaths; pulmonary tuberculosis, 121 cases, 69 deaths; pneumonia, 206 cases, 144 deaths; erysipelas, 11 cases, 3 deaths; septicaemia, 2 cases, 1 death; mumps, 6 cases, 0 deaths; cancer, 10 cases, 0 deaths. The following deaths were recorded from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 9; puerperal fever, 3; tetanus, 1; diarrhoea and enteritis, under two years of age, 14. The total deaths numbered 705 in an estimated population of 1,532,738, corresponding to an annual death rate of 23.90 in 1,000 of population. The total infant mortality was 133; under one year of age, 107; between one and two years of age, 26. There were 48 still births—25 males and 23 females. The total precipitation was 0.87 inch.

**College of Physicians of Philadelphia.**—At the regular meeting, held on Wednesday evening, February 5th, the evening was devoted to a symposium on aneurysm, papers being read as follows: A Case of Multiple Sacculated Thoracic Aneurysm Successfully Treated by Wiring, by Dr. James M. Anders; Sacculated Aneurysm of the Arch of the Aorta Ruptured into the Superior Vena Cava, without Symptoms of Venous Obstruction, by Dr. Joseph Sailer; The Pathogenesis of Aneurysm of the Aorta, by Dr. Joseph McFarland; The Early Symptomatology of Aneurysm of the Aorta, with Special Reference to the Differential Diagnosis, by Dr. J. Dutton Steele; The X Ray Diagnosis of Aneurysm of the Aorta, by Dr. Henry K. Pancost; The Wiring Operation in the Treatment of Aneurysm of the Aorta, and the Influence of Drugs Before and After the Operation, by Dr. Hobart Amory Hall. The honorary librarian announced the addition of fifty-two volumes to the library during the month of January, and the curator of the Mitter Museum announced the addition of one specimen to the museum. A committee has been appointed to secure a portrait of the late president, Dr. Arthur V. Meigs.

**Meetings of Sections of the New York Academy of Medicine.**—The Section in Neurology and Psychiatry will meet on Monday evening, February 10th, at 8:15 o'clock. Dr. William B. Pritchard will present two cases of Major Hysteria, and Dr. M. G. Schlapp will present a case of Unusual Tonic Muscular Spasm and a case of Hemiatrophy of the Face. Professor Joseph Jastrow, of the University of Wisconsin, will read a paper entitled Mental Abnormality as Exaggeration of Temperament. This paper will be discussed by Dr. Carlos F. MacDonald, Dr. William Mabon, Dr. Smith Ely Jelliffe, and others.

The Section in Public Health will hold a meeting on Tuesday evening, February 11th, at 8:15 o'clock. Dr. George A. Soper will read a paper on the Objects of Ventilation; Professor William H. Hallock, of Columbia University, will read a paper on the Principles of Ventilation; and a paper on the Application of Ventilation to Buildings will be read.

At a meeting of the Section in Paediatrics, which will be held on Thursday evening, February 13th, at 8:15 o'clock, the following papers will be read: The Indications for Stimulants in Paediatric Practice, by Dr. Sara Welt-Kakels; the Use of Analgesics in Paediatric Practice, by Dr. Le Grand Kerr, of Brooklyn; the Place of Hydrotherapy in Paediatrics, by Dr. Friedrich K. W. Grosse; the Principles of the Climatic Treatment of Children, by Dr. F. W. Wachenheim. The discussion will be opened by Dr. Henry Koplik.

The following programme has been arranged for a meeting of the Section in Otolaryngology to be held on Friday evening, February 14th, at 8:15 o'clock: Presentation of patients: A Case of Carcinoma Springing from the External Auditory Canal, by Dr. Emil Gruening; four cases showing the Results of Ossiculotomy, by Dr. W. H. Haskin;

current Fibroma of the Lobule, by Dr. G. B. McAuliffe. Presentation of specimens: A wet specimen of temporal bone, by Dr. W. H. Haskin. Reports of Cases: A case of Meningitis of Otic Origin, by Dr. P. D. Kerrison; a case of Cerebral Abscess with Aphasia, by Dr. B. F. Knause.

#### Society Meetings for the Coming Week:

**MONDAY, February 10th.**—New York Academy of Medicine (Section in Neurology and Psychiatry); Society of Medical Jurisprudence, New York; New York Ophthalmological Society; Corning, N. Y., Medical Association; Waterbury, Conn., Medical Association.

**TUESDAY, February 11th.**—New York Academy of Medicine (Section in Public Health); Medical Society of the County of Schenectady, N. Y.; Practitioners' Club of Jersey City, N. J.; Medical Society of the County of Rensselaer, N. Y.; Buffalo Academy of Medicine (Section in Medicine).

**WEDNESDAY, February 12th.**—New York Pathological Society; New York Surgical Society; Medical Society of the Borough of the Bronx; Alumni Association of the City Hospital, New York; Brooklyn Medical and Pharmaceutical Association; Richmond County, N. Y., Medical Society.

**THURSDAY, February 13th.**—New York Academy of Medicine (Section in Paediatrics); Brooklyn Pathological Society; Blackwell Medical Society of Rochester, N. Y.; Jenkins Medical Association, Yonkers, N. Y.

**FRIDAY, February 14th.**—New York Academy of Medicine (Section in Otolaryngology); New York Society of Dermatology and Genitourinary Surgery; Eastern Medical Society of the City of New York; Saratoga Springs, N. Y., Medical Society.

**Personal.**—Dr. Lee K. Frankel, for nine years manager of the United Hebrew Charities of New York, has tendered his resignation, to take effect on May 1st, in order to undertake important investigations on behalf of the Russell Sage Foundation.

Dr. Howard L. Kaucher will hereafter be associated in practice with Dr. C. R. P. Fisher, at 224 Somerset street, Bound Brook, N. J.

Dr. Herbert Leslie Burrell has been appointed John Homans professor of surgery at the Harvard Medical School.

Dr. T. A. Williams has taken up his residence in Washington, D. C., after having spent two years in the study of nervous diseases in Paris and other European countries. He has been requested to give a course of instruction, embodying the more recent researches of the French school in the diagnosis and treatment of the psychoneuroses. The number of pupils will be limited, as individual attention will be given to each and the whole day devoted to study.

**Charitable Bequests.**—By the will of Adeline S. Lyon the Rush Hospital, St. Christopher's Hospital, and the Kensington Hospital for Women receive \$1,000 each. The Visiting Nurse Society, Gwynedd Home for Convalescing Children, Northern Day Nursery, Children's Aid Society, and the Children's Country Week Association receive \$500 each.

By the will of William H. Burns the Frankford Hospital receives \$25,000 for permanent improvements.

By the will of Lucy Emily Carr, the Somerville, Mass., Hospital receives \$5,000.

By the will of Frances E. Koons the Hahnemann Hospital Philadelphia, will receive \$3,000 for the endowment of a free bed.

By the will of Mrs. Elizabeth S. Folsom the Exeter, N. H., Cottage Hospital will receive \$10,000.

By the will of Joseph Hegle, the Little Sisters of the Poor, of Philadelphia, will receive \$500, and St. Vincent's Orphan Asylum receives \$200.

By the will of Bridget Reilly, her residence is given to the Philadelphia Protector for Boys. St. Vincent's Home, the Maternity Hospital, the House of the Good Shepherd, St. Joseph's House for Industrious Boys, and the Home for Children and Infants, Philadelphia, become reversionary legatees.

By the will of William Jones, the Columbus State Hospital, Columbus, Ohio, receives \$3,630.

By the will of James Lambert the Pennsylvania Hospital receives \$50,000 and the Free Hospital for Poor Consumption, at White Plains, N. Y., receives \$10,000.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL.

January 30, 1908.

1. An Insidious Type of Nontuberculous Pyelonephritis.  
By ARTHUR L. CHUTE.
2. Adenoids and Tonsils. From the Standpoint of the General Practitioner, with Special Reference to an Examination of the Throat in Chronic Systemic Infections and a Consideration of the Question of Status Lymphaticus in these Cases.  
By HENRY GLOVER LANGWORTHY.
3. Division of the Posterior Spinal Roots for Amputation Neuralgia.  
By PHILIP COOMBS KNAPP.
4. The Reform of Expert Medical Testimony.  
By L. C. SOUTHARD.
5. Spina Bifida,  
By BENJAMIN BRABSON CATES.

1. **An Insidious Type of Nontuberculous Pyelonephritis.**—Chute reports two such cases, which represent a class in which infection with a nontuberculous organism either ascends to the kidney, or if it does not ascend begins as a surface infection of the kidney pelvis, and in which the process of destruction is a slow erosion of the secreting tissue. The clinical picture in this type of pyelonephritis is that of cystitis. As the symptoms of cystitis persist, but without the great increase in frequency and pain that is often seen in tuberculous cystitis, the patient gets accustomed to the discomfort, and the process extends insidiously, in that there is the addition of no new or startling symptoms until the renal tissue is destroyed to such a degree that the patient has a deficient power of elimination. The duration of this insidious progression may be several years. The failure of the power of elimination and the appearance of symptoms that mark the true character of the process occurs only when both kidneys are involved to such an extent that they have a combined power of elimination that is less than that of one normal organ. At this time it will be too late to attempt operative measures successfully. The symptoms in these cases, during the time that it is possible to stay the process, point to the bladder, though the lesion is of the kidneys. Cystoscopy in these cases will be of great help to make a proper diagnosis. Early treatment by means of drainage is probably our most efficient means of treating these cases.

2. **Adenoids and Tonsils.**—Langworthy remarks that there are two points of interest in considering the question of the status lymphaticus in these cases. In regard to the first point, whether a diagnosis can be made during life, the author observes that it may be stated that a positive diagnosis is, to say the least, extremely difficult, if not impossible. The diagnosis is certain only when verified by a most careful autopsy. Nevertheless, such a disorder should be borne in mind, especially if attention is drawn to it by any suspicious circumstances. In considering the second point, whether cases of greatly enlarged adenoids and tonsils are more likely to fall in this class than individuals who are not so affected, Langworthy says that it would seem reasonable to suppose that cases of simple adenoid and tonsils should not in themselves present reasons for doubt or anxiety in this respect. It is only when they are associated with other stigmata

as, for instance, absence of pubic hair in an adult, frequent attacks of syncope, dyspnoea, and laryngismus stridulus, etc., that the possibility of a constitutio lymphatica should be considered. As the list of fatalities increases we find death from all manner of slight causes, such as antitoxine injections, bathing, convalescence from acute infectious diseases, labor, etc., and from both ether and chloroform. The best method of removal of tonsils and adenoid in these cases when they are but moderately enlarged and yet undoubtedly the cause of some disturbance consists in removing thoroughly the tonsil, including the capsule. It is the only method of procedure which can guarantee immunity from further infection. The tonsillotome so frequently used will not answer the purpose. It is about as surgical to leave large pieces of the tonsil in some part of the sinus tonsillarum as it is to excise but a portion of the appendix in an appendectomy. Incision, cauterization, or partial decapitation does not meet the condition. The offending organs should be eradicated by scissors, snare, or punch, and even the base curetted if necessary to secure a sound wall of tissue behind. The same applies to the adenoid, and, after the removal of the adenoid with whatever instruments are used, the nasopharynx should be carefully cleaned out with the finger until smooth and free from all offending shreds. Adenoids and tonsils rarely recur after this systematic attention. A so called regrowth in such instances is usually a fair evidence that the entire organ was never removed.

By HEINRICH STERN.

1. **Conservative Operations on Bone Tumors.**—Bloodgood remarks that there are two varieties of bone cysts. The dentigerous cyst is observed in the jaws. Undoubtedly it arises from an embryonic residue, mesoblastic or epiblastic, of the dental tissue. This cyst originates within the bony cavity of the upper or lower jaw, and in its growth expands the bone, producing a cystic tumor with a bone capsule. The cyst can be recognized only at an exploratory incision, when it is found that it usually contains only clear, viscid serum. In order to accomplish a cure, it is simply necessary to remove the membranous lining. The amount of bone capsule to be excised should be governed by the extent of the deformity; resection of the jaw is never indicated. The second variety of bone cysts occurs in the medullary cavity of the long bones, rarely in the short and flat bones. It differs from the dentigerous

cysts in the absence of a connective tissue capsule. The fluid is usually hemorrhagic. Islands of cartilage may be found in the bone capsule. Clinically there is a uniform expansion of the shaft, usually near the joint end, of slow growth. Fracture may be the symptom of onset. Union may take place, but the swelling does not disappear. The x ray shadow does not differ from that seen in any medullary tumor which produces in its growth bone absorption and retains a bony capsule. The benign nature of the lesion can only be ascertained with certainty at the exploratory incision. Curetting and drainage of the cyst will accomplish a cure. The adamantine epithelioma cannot be distinguished clinically from the dentigerous cyst when it arises within the bony cavity of the jaw, nor from the so called epulis, when it begins beneath the mucous membrane of the alveolar border of the jaw. At the exploratory incision the adamantine epithelioma can be distinguished from the dentigerous cyst by the coarse, white granular tissue filling the single or multiple cavities. This tumor must be completely excised with its bony wall, but in the excision one can keep close to the tumor. When the adamantine epithelioma occurs as an epulis, local removal with excision of the alveolar border of the jaw only is necessary. Giant cell sarcoma usually originates in the medullary cavity of the long bones, although periosteal growths have been recorded. It is the most common form of epulis, which may be looked on as a periosteal growth from the alveolar border of the jaw. One should not attempt curetting in these tumors unless there is a thick shell of bone. When this shell is thin, subperiosteal resection should be performed; when the periosteum and surrounding muscles have become infiltrated total resection is indicated. For the periosteal giant cell tumor local resection with chiseling of a zone of bone beneath is sufficient. The pure myxoma is a very rare tumor. It may occur as a medullary growth or as a periosteal exostosis. In the former it is associated with the bone shell; in the latter with a partial bony wall. The myxomatous appearance of the tissue is sufficiently characteristic to allow a diagnosis. This tumor should be subjected to the same treatment as giant cell sarcoma. There is no difficulty in recognizing pure enchondroma; it is benign, and local resection is sufficient. In myxochondrosarcoma the cartilage and myxomatous tumor usually occur together and most often with sarcomatous degeneration. The author has observed periosteal fibroma only in the jaw, when local excision is sufficient. Exostosis buritis is a benign lesion which clinically may resemble a rapidly growing sarcoma. The congenital small exostosis springing from the outer table of the bone gives no symptoms. The first rapid swelling observed by the patient is due to the filling of the bursal sac with fluid. Clinically there is a rapidly growing, tense tumor, apparently of periosteal origin. Unless x rays are taken from numerous directions the exostosis may be missed. This lesion is recognized at once if an exploratory incision is made.

6. **The Antimicrobial Action of Bromine.**—Kinnaman divides the results received from his experiments into two classes. The absolute death

sure to same; and the power of solutions to inhibit growth of microorganisms, depending also on strength of solution and time of exposure to same, exhibited as a forerunner of absolute death. A very wide range in efficiency of solutions is found to exist between *Streptococcus pyogenes* and *Bacillus anthracis*. The effectiveness of solutions is exhibited in three main groups: (1) Group 1, consisting of *Streptococcus pyogenes* and *Staphylococcus pyogenes aureus*, where the antimicrobial power is extremely well marked, being almost specific for both microorganisms, but of special importance for its effect on *Staphylococcus pyogenes aureus*; (2) Group 2, consisting of *Actinomyces* and *Blastomyces*, where less efficiency is shown, but where the effect is still very satisfactory; (3) Group 3, consisting of *Bacillus prodigiosus*, *Bacillus tuberculosis*, and *Bacillus anthracis* plus spores, where there is a very considerable slump in efficiency of solutions. On the spore forming *Bacillus anthracis* the effect is very unsatisfactory. Taking for consideration the inhibition in growth of microorganisms due to actions of solutions on them, which depends jointly on the strength of solutions employed and the time of exposure to same, the author says that in the cocci group, the inhibitory sphere, though vigorous and progressive in character, is very restricted because of the close approximation of the points at which inhibition and death occur. In the fungi group, from the same cause, the sphere of inhibition is again very restricted, though progressive in character. It presents a slightly greater range in inhibition than does the cocci group. In the bacilli group, where, from the tardy appearance of the death point, we would expect to find a long and progressive sphere of inhibition, we find just the opposite. Here, due to the tardiness of its appearance, we get an inhibitory sphere rather contracted in character and one which is markedly irregular in type, giving one the impression of being highly unreliable. Progressiveness in action is strikingly absent. In a solution of bromine, the author thinks, we have a germicidal agent that presents a peculiar selective action for certain groups of microorganisms, and then acts more or less indifferently toward another group. In other words, on cocci and fungi a 1 in 300 solution is effective in a brief time, thus exhibiting a very marked germicidal action on them. On the other hand, on bacilli, especially spore forming, the germicidal effect of solutions is disappointing, a one per cent. solution having to act for a very considerable period of time before death is produced. It differs from an ideal antiseptic in that it is hard to prepare, being extremely irritating to eyes and mucous membranes, and is very unstable, having to be kept in a glass retainer. Even then it loses its power gradually, hence fresh solutions have to be made frequently. As it is not markedly penetrating, it has to act for a considerable period of time to be effective on all microorganisms, and it coagulates albumin. But it is nontoxic and nonirritating in a strength that is effective, and does not produce an appreciable stain. It is necessary to use a one per cent. solution for the period of one hour to be effective.

9. **Iodoformic Acid in the Treatment of Chronic Ulcerative Phthisis.**—Stern, of New York, attributes the primary therapeutic effect of the

iodoformic acid in chronic ulcerative phthisis to a local condition. He bases this opinion on the following clinical facts, viz.: The pain in the chest, when present, is relieved after a few injections; the cough soon loses its paroxysmal character when the patient is under the influence of the drug; the expectoration, which may have been profuse, becomes scanty and attains a less purulent character, and the bacterial flora of the sputum (with exception of the bacillus tuberculosis) becomes perceptibly reduced after ten or fifteen injections. The elastic tissue fibres and the tubercle bacilli do not disappear so readily from the sputum, but in the majority of cases they are no longer found in it after from five to seven months' treatment with the iodoformic acid. The one per cent. solution participates in the removal of the decaying material from the lungs and tends to check ulceration and caseation. Its continued administration favors sclerotic metamorphosis of the margins of the ulcerating area and subsequent fibrosis and calcification of the entire diseased lung tissue. The mediate therapeutic effect of the drug is constitutional. Iodoformic acid seems to influence assimilation and anabolism in an independent and rather direct way, which is evidenced by the facts that the nourishment is better utilized and that the patient begins to gain in weight soon after the treatment is instituted and before any appreciable local changes have been brought about. Such local changes of improvement are, of course, preceded by the usually early relief of the symptoms. (See Therapeutical Notes, page 264.)

By O. L. MCLOD.
7. Congenital Irideremia with Cataract.  
By EDGAR S. THOMSON.

3. **Cutaneous Tuberculin Vaccination in the Diagnosis of Tuberculosis.**—Butler remarks that the cutaneous tuberculin vaccination commends itself because of its simplicity of application, and because it is unattended by any febrile reaction. The technique the author describes as follows: Make a 25 per cent. solution of old tuberculin in salt solution. A similar dilution is used in which one volume of a 5 per cent. solution of carbolic acid in glycerin is substituted for one of the volumes of salt solution. Place two drops, one of each solution, separated from each other by a space of two inches, on the outside of the arm, which should be prepared as is customary for vaccination. A small lancet, with a dull tip, which is about one sixteenth of an inch wide and placed vertically in a metal handle, is used to abrade the skin through the vaccine drops by a rotary motion, removing only upper layers of epidermis. The tip is then cleaned, and at a point midway between the vaccination marks a third abrasion is made, without any tuberculin being applied,

to serve as a control. If the reaction is positive a papule, varying in size from 5 to 20 mm. in diameter, at first bright red, later becoming a dark red with a slight areola, will appear at either vaccination point, in the first twenty-four hours; occasionally they are delayed to the second twenty-four hours. Sometimes little vesicles with turbid contents, later becoming confluent, appear over the inoculation site. These fade and disappear in course of several days, leaving at times a little pigmentation. In positive cases in which revaccination is practised similar reactions result. In localized tuberculous processes, as of the glands and bone, the reaction is especially marked in contrast to the milder reaction seen in persons who have healed foci. At the control point, and at all three points, in case the reaction is negative, the slight reddening that follows the scarification disappears in twenty-four hours without any further changes.

5. **Treatment of Cancer.**—Henry observes that the germ theory of this disease may be dismissed as being irrational and pretty thoroughly discredited. But that it is due to faulty nutrition, assimilation, and absorption we may fairly assume, and these conditions are brought about by one or more of a variety of causes. As regards nutrition, we recognize three ways which make for a departure from health—overnutrition, undernutrition, and faulty nutrition. By this last is meant that, while there may not be too much or too little food taken, the material composing it is deleterious. In the first case, that of overnutrition, too much food is taken, more than the body needs for its proper maintenance. As time goes on and this condition of things continues, the blood making organs become tired and manufacture less perfect material from which the "builders" at some one or more selected places begin to replace with imperfect or cancer cells the more normal tissues of the affected parts. As the eliminative absorbents fail to remove this imperfect material as fast as it is deposited, we have the growing tumor. Though less frequently, much the same conditions obtain in undernutrition. The blood making organs themselves are poorly nourished and furnish poor material for the building of perfectly healthy cells. By material which gives a faulty nutrition the author means all flesh foods which, containing toxins and poisons of various kinds, are totally unfit for human consumption and have much to do either directly or indirectly in bringing about a condition of things that goes to the building of cancers. If cancer is a local disease, it should not return after removal, as it usually does. On the theory that there is a general wrong condition of the blood making assimilative and eliminative functions, it is readily explainable; for usually nothing is effectively done after an operation for the removal of the growth to remedy the wrongs; and not only that, but the patient's strength is seriously sapped by the operation itself, if that operation has been accomplished by knife or plaster. Thus an early recurrence is to be looked for. The author thinks that cancer of the breast, when not too large and near the suppurative stage, can be treated with the greatest promise of success with electricity and massage, both local and general, together with a special diet from which all flesh foods are entirely ex-

cluded. The patient should always be under the physician's immediate care, at his residence or private sanatorium, where every detail of the treatment can be most thoroughly carried out.

# BRITISH MEDICAL JOURNAL.

5. Some Physiological Aspects of Gastroenterostomy, By H. C. CAMERON.
6. Ether Anæsthesia by the Open Method, By H. B. GARDNER.
7. The Conveyance of Whooping Cough from Man to Animals by Direct Experiment, By H. A. MACEWEN.

**1. Preparation of Catgut.**—Lister states that catgut used for surgical purposes should fulfill the following conditions: It should, after soaking in water or blood serum, be strong enough to bear any strain to which it may be subjected, and should hold perfectly when tied in a reef knot. It must not be so rigid as it lies among the tissues as to have any chance of working its way out by mechanical irritation. Nor should it be too quickly absorbed, but should be consumed so slowly by the cells of the new tissue that grows at its expense that, in the case of the ligature of an arterial trunk in its continuity, it may serve sufficiently long as a support for the substitute living thread in its embryonic condition. At the same time it is essential that the catgut be securely aseptic when applied. Chromium sulphate is an ideal substance for the preparation of catgut, with the exception that it is utterly untrustworthy as a germicide. This defect is easily remedied by the addition of a little corrosive sublimate. The preparing liquid must be twenty times the weight of the catgut, and is prepared by mixing the following solutions: (a) Corrosive sublimate, 2 grains; distilled water, 320 minims. (b) Chromic acid, 4 grains, distilled water 240 minims, to which is added enough sulphurous acid to give a green color. The catgut is kept twenty-four hours in the preparing liquid and is then dried on the stretch. But while the substance of the catgut is antiseptic as well as aseptic, its dry surface is liable to contamination by contact with septic material, and it is essential that, before being used, it is washed with some trustworthy germicidal liquid. The writer puts the catgut, like the instruments, in 1 to 20 solution of carbolic acid about a quarter of an hour before the operation is begun.

**3. Passage of Food Through the Pylorus.**—Hertz, as a result of his studies, concludes that the passage of food through the pylorus is not regulated by reflexes from the duodenum alone. When solid masses in the food are carried against the pylorus, it closes and remains closed for a time. The result is that indigestible masses remain in the stomach until all the fluid and semifluid contents have left, so that more time is given to the gastric juice to soften and break up the insufficiently chewed food. By a similar protective mechanism, fluids at higher or lower temperatures than that of the body leave

the stomach less rapidly. So that the stomach has a function which is not generally recognized; it protects the duodenum from abnormal stimuli by retaining food until it is changed so as to be less injurious to the delicate intestinal mucous membranes. Proper chewing will spare the stomach most of its work; it will divide the food into fine particles, dilute it, and bring it to body temperature. Stasis of food in pyloric ulcer is usually thought to be due to reflex spasm of the pylorus. More probably it is due to reflex inhibition of the relaxation which normally occurs on the arrival of a peristaltic wave. Indeed, it is doubtful whether spasm of the pylorus ever occurs.

**5. Gastroenterostomy.**—Cameron, from a study of the physiological phenomena in cases of gastroenterostomy, reaches the following conclusions: 1. On a purely milk diet, in nonmalignant cases, after gastrojejunostomy, there is a slight but definite diminution in the power of digesting and absorbing fat. 2. On a mixed diet, rich in fat, for the most part in the form of butter, this diminution in power disappears. 3. On a milk diet and on a mixed diet, rich in fat, the results are the same, whether there is obstruction at the pylorus or not. It is, therefore, improbable that the diminution in power of digesting milk depends upon whether the duodenum is or is not short circuited out of the alimentary canal. The cause must be common to both obstructed and nonobstructed cases, and is probably to be found in the regurgitation of alkaline bile and pancreatic juice into the stomach, and in the consequent reduction of gastric acidity, together with the inhibition of the rennin. 4. That in cases of recurrent intractable duodenal or gastric ulceration, an operation is indicated which will ensure the complete loss of the acid reaction of the stomach, while the benefit at present conferred in ulceration by gastroenterostomy is due to the partial loss of that reaction. That such an operation would consist in closing the proximal end of the bowel and implanting the distal directly into the stomach. That where gastroenterostomy is performed, the opening should be near the cardiac end of the stomach, and that the anastomosis should be simple, not Y shaped, nor with enteroenterostomy. 5. That the complete digestion of fats on a mixed diet is due to the specific stimulating effect on the pancreas of a hormone produced by the fats themselves. 6. A case of malignant pyloric obstruction, after partial gastrectomy and posterior gastrojejunostomy, showed complete power of dealing with fats.

**7. Conveyance of Whooping Cough.**—Macewen, by feeding a cat on sputum and vomited material from cases of whooping cough, found that two weeks later the animal became languid; after two weeks more it developed a choking cough which was always followed by vomiting, and still later a spasmodic cough with a well marked whoop. The conclusions drawn are as follows: 1. Whooping cough is beyond doubt an infectious disease. 2. The specific virus is contained in the sputum, or vomited material, or both. 3. Infection may take place either during the process of swallowing or by ingestion of the infective agent. 4. Cats are susceptible to whooping cough, and may therefore occasionally be the means of disseminating the disease.

10. Electrolytically Produced Fluids Containing Hypochlorites, Their Manufacture, and the Rationale and Chemistry of the Process for Securing Stability, By F. W. ALEXANDER.

1. **Erythræmia.**—Osler reports a case of erythræmia—a disease characterized by cyanosis, enlargement of the spleen, and a condition of polycythæmia. The hands, feet, and face are cyanotic and of a dusky hue. The vasomotor instability is very marked, the hands and feet becoming dark blue when kept in a dependent position. The skin shows just the opposite condition to the *tache cérébrale*—along the line of irritation there is a vasomotor constriction in the small arterioles, and the line stands out as a band of anæmia. The spleen is usually markedly enlarged and its notch can be readily felt. The blood flows in a large drop from the finger or ear when pricked, and is sensibly richer in color and unusually viscid. For the recognition of the disease a blood count is necessary, not simply a blood examination, as in leucæmia. The essential feature—the polycythæmia—can be determined only by counting the number of red corpuscles in a cubic millimetre of blood. A true polyæmia, a plethora vera, is present. Many other additional symptoms have been noted, such as pains in the hands and feet, headache, and constipation. High blood pressure is the rule and sclerosis of the superficial arteries and a trace of albumin in the urine have been frequently observed. Post mortem, the following anatomical changes are found: A plethora vera; intense hyperplasia of the bone marrow, a myelomatosis rubra; and enlargement of the spleen, with histological changes, indicative of chronic passive congestion, a uniform hyperplasia of all its elements. It may be that the spleen participates actively in the process; neither it nor the lymph glands lose their power of making red blood corpuscles. But the essence of the disease is still a mystery, the over supply of red corpuscles, without any corresponding demand. Very little is known about the treatment of the disease. As a long experience with leucæmia has demonstrated, we have nothing at our disposal which controls the morbid processes in the bone marrow. When there are fullness of the head and vertigo, repeated bleedings often give great relief. Inhalations of oxygen are stated to have been very beneficial in some cases, relieving the

cyanosis and diminishing the number of red corpuscles, which in some cases rises as high as 12,000,000 corpuscles per cubic millimetre, over double the normal.

2. **Tropical Liver Abscess.**—Bradshaw states that the most noticeable features of tropical abscess, as distinguished from other forms of suppuration in the liver, are that it is most often a single abscess, that it generally attains a large size, and so gives indications of its presence, that it is not as a rule associated with general pyæmia, and is not dependent upon any antecedent coarse disease of the liver. This type of abscess is rarely found except in persons who have lived in tropical or subtropical countries, and it affects Europeans more often than natives. The exact causes which determine its formation are not exactly understood. Habitual overfeeding and indulgence in alcohol are credited with a share in its production, but the cause which overshadows all others by its frequency is the occurrence of dysentery. Whether bacillary dysentery in tropical regions can give rise to abscess, or whether the amœbic variety alone can do so, is still *sub judice*. While the contents of a large number of liver abscesses are sterile as regards bacilli, the majority of abscesses associated with amœbic dysentery do actually contain amœbæ. The successful treatment of tropical abscess by surgery depends on its being single, or at most double. The symptoms are often indefinite, comprising chiefly weakness and lassitude, loss of flesh, a sallow, muddy complexion, and sensations of chilliness or actual rigors. Pain in the right shoulder is a time honored symptom of abscess in the upper part of the right lobe of the liver, and is explained by radiation along a small branch of the subphrenic nerve, which communicates with the nerve to the subclavius muscle. Enlargement of the liver in an upward direction is almost pathognomonic of liver abscess, but it is not easy to recognize. The chief difficulty in diagnosis in abscess of the liver arises from its simulating disease of the right lung or pleura, or from its being complicated with actual effusion into the pleura.

6. **Arteritis Obliterans.**—Weber reports the case of a Russian Jew, aged forty-two years, suffering from obliterating arteritis of the left lower extremity, with intermittent claudication (*angina cruris*). His chief complaint was of cramplike pains in the inner part of the sole of the left foot (muscles of the instep) or in the calf of the left leg, which always attacked him after he had walked for three or four minutes, and obliged him to rest for a few minutes before going on. No pulsation could be felt in the arteries of the left foot. The essential cause of the arterial disease in these cases is unknown; possibly it is due to imperfect development. There is great analogy between the phenomena of arterial obstruction in the leg and those of *angina pectoris*. Just as there are cases of *angina pectoris* (pseudoangina) without organic disease of the coronary arteries, so there are probably also cases of intermittent claudication of the extremities without organic arterial disease—a *dysbasia intermittens angiospastica*, in contradistinction to *dysbasia intermittens arterioscleretica*.

The Neurites Which Occur in the Course of Cirrhosis of the Liver, By M. KLIPPEL and J. LHERMITTE.

**Neurites in the Course of Cirrhosis of the Liver.**—Klippel and Lhermitte allege that peripheral neurites may appear at very diverse periods in the evolution of an alcoholic cirrhosis of the liver. In some cases they seem to mark the commencement of the cirrhosis, in others they become manifest in the later stages of the disease. The two types, very different in their clinical aspect and in their lesions, are not of equal interest. In the one case the neurites are masked as it were by the multiplicity of the cachectic symptoms, while in the other they are from the first rendered prominent and striking by their intensity. The neurites which appear in the final stage of cirrhosis are not very frequent and are due to degenerative lesions, the character of which is striking as compared with the inflammatory character of ethylic polyneuritis. In all other forms of neuritis which are manifested during the course of cirrhosis the symptoms are extremely severe and the lesions on which they depend very pronounced. In other words in most cases of polyneuritis associated with alcoholic cirrhosis of the liver the neuritis is a classical alcoholic polyneuritis. Several cases are described and the literature on the subject is extensively quoted.

10. The Curability of a Rare Form of Nocturnal Petit Mal by the Use of Large Doses of Bromide, By L. P. CLARK.
11. The Action of the Nitrites on the Heart, By W. de B. MACNIDER.
12. Otitis Media and Its Treatment, By E. C. ELLETT.

1. **The Diagnosis and Treatment of Cardiovascular Renal Disease.**—Tyson affirms that this association of diseased organs is of frequent occurrence. The arteriosclerosis or angiosclerosis invades especially the smaller vessels, and the associated hypertrophy of the left ventricle (less frequently of both ventricles) is due to effort to overcome arterial resistance, and to the stimulus of irritating blood. All the chambers of the heart may be hypertrophied. While general arteriosclerosis may

be primary, it is usually secondary to renal contraction. Albumin and casts usually appear early in the primary renal cases. In general arteriosclerosis there may be hyaline casts, but no albumenuria, while brain symptoms, anæmic symptoms, retinal changes, emaciation, and pallor appear early and are prominent. In the latter condition increase of blood pressure is less marked than in the former. The prognosis is more favorable when the heart disease is primary, even when there is extensive dropsy. Treatment may be helpful, but not curative. Sodium iodide, tincture of aconite, nitroglycerin, nitrites, and general massage are indicated for treatment. Rest in bed and milk diet are indicated, though the latter is contraindicated if the tissues are oedematous. Diuretics and hydragogue cathartics should be given when such a condition obtains.

2. **Treatment of Pneumonia Especially by Outdoor Air.**—Thompson refers to 128 cases of acute lobar pneumonia treated in the Presbyterian Hospital in New York in 1906, of which number forty-seven patients among those who recovered received no medicinal treatment. They were either on the roof or in small rooms in which the windows were constantly open. The author thinks the only rational treatment of pneumonia is the symptomatic one, and that in every case an abundant supply of fresh outdoor air is the first requisite. He thinks this method of obtaining oxygen infinitely superior to obtaining it from a metal cylinder after being superheated and then blown through stale water and an unpleasant rubber tube. He thinks the fear of the draught in the case of pneumonia is due to prejudice or inexperience. The open air treatment will not cure all patients with pneumonia, but it will do more for most of them than drugs. At the same time there are certain symptoms which call for the use of drugs, and when such symptoms are apparent the proper drugs should not be withheld.

4. **The Diagnosis and Treatment of the Gastric Neuroses.**—Cheney means by gastric neuroses those cases of stomach trouble in which there is constant complaint of discomfort during digestion, but no evidence of organic disease. Neurasthenia is usually an underlying cause. As to prognosis, one must bear in mind (1) that ulcer or malignant disease may be present, (2) that a cure depends largely upon change in the patient's mode of living. The treatment demands simplicity in diet and habits, slow eating with careful mastication, resting after meals, and avoiding worry. The quantity and quality of the diet is to be determined by analysis of the test meal. Hyperacidity, subacidity, or faulty motility will be revealed by such an analysis, and the proper diet and drugs will be formulated in accordance with such findings.

5. **Diagnosis and Treatment of Infections of the Biliary Passages, with Special Reference to Cholelithiasis and Cholecystitis.**—Deever divides the surgical treatment of these conditions into (1) the indications for such intervention, (2) the results of such intervention, (3) the contraindications. The indications are (1) repeated attacks of biliary colic, (2) dropsy of the gallbladder, (3) stone in common duct, (4) complications, especially the acute infections. Spontaneous cure of cholelithiasis

is rare, cure by medicines impossible. The same is true in regard to the adhesions excited by the disease. The results of surgical intervention in the author's series of 217 cases show death in thirty cases from all causes. The contraindications to surgical intervention are organic lesions of the heart, lungs, and kidneys, extreme age, anæmia, or slow coagulability of the blood, and cholæmia. Surgical treatment is absolutely necessary to a cure in most cases of chronic biliary infection, and if undertaken early offers far greater chances of success than when complications have occurred.

**6. Rupture of the Kidney.**—Neilson reports four cases in which this accident occurred which were treated conservatively, rather than by nephrectomy. He also analyzes the somewhat abundant literature of the subject, and finds that the advantage lies with conservative treatment. Surgical interference is called for to control hæmorrhage and prevent extravasation of blood and urine into the tissues and abdominal cavity, also to treat other organs which may have been injured simultaneously, and, finally, to place the injured kidney under conditions which shall be most favorable for repair, including the providing of means against the occurrence of infection. An operation, if indicated, should not be delayed. It goes without saying that the injury is so slight in many cases that an operation is not required. The conditions must be carefully weighed to decide between an abdominal or a lumbar incision. The pressure of gauze packing properly applied will usually control hæmorrhage, and drainage must be facilitated by the use of a sufficient number of rubber tubes. The injured kidney should be sutured if possible.

**8. The Röntgen Ray Treatment of Hypertrophied Prostate.**—Hunter notes the failure of medical treatment to relieve this condition, also the fact that radical removal of the organ is accompanied by high mortality. The application of the Röntgen ray is suggested in view of its atrophying action upon glandular tissues. This plan has been tried with success in a number of cases. The danger of exciting inflammation in the mucous membrane, which offers slight resistance to the rays, must not be overlooked. The author thinks the best results are to be obtained when the hypertrophy is only of the first or second degree, rather than in cases in which sclerosis is excessive. He believes this method is superior to all others for any except the oldest and hardest prostates, which must be removed surgically.

15. The Open Method in the Treatment of Pott's Fracture of the Leg, By H. H. HEATH AND C. D. SELBY.
16. Punctured Fracture of the Skull, By G. G. ROSS.

**1. The Relation of the Mesocolic Band to Gastroenterostomy.**—Mayo denies that anterior gastroenterostomy has become obsolete, though its field of usefulness has been greatly diminished by the posterior method, by which the intestinal loop has been eliminated. By the anterior method from sixteen to twenty inches of jejunum must be looped around the transverse colon, and regurgitation of bile is often one of its annoying complications. In performing the posterior operation the author suggests that the operator locate the peritoneal suspensory ligament or band which extends from the transverse mesocolon to the upper part of the jejunum. Immediately above this band, in the mesocolon, is an area in which there are no important blood-vessels. The suspensory band having been stripped away, and a transverse incision made in the above mentioned area of the mesocolon, the posterior aspect of the stomach may be drawn through this opening and the denuded jejunum attached to it, the attachment thus being without strain or loop and following the normal direction of the jejunum.

**4. A Contribution to the Diagnosis of Renal Tuberculosis.**—Campbell analyzes eleven cases of this condition. In one a circumurethral abscess was the first objective sign, in three there was epididymitis subsequent to the primary renal symptoms, and in one there was pulmonary tuberculosis when the renal disease was discovered. In nine of the cases tubercle bacilli were found in the urine. All but two of the cases underwent nephrectomy, and the clinical diagnosis was verified. Two of the cases developed probable tuberculous disease after the nephrectomy, and another quickly succumbed to general miliary tuberculosis. The cystoscope aided in the diagnosis, ulceration, tubercles, or œdema being observed around the ureteral orifices. The ureteral catheter also permitted collection of urine from each kidney with certainty. With such assistants, and the possibility of an early diagnosis and a primary unilateral disease, the prognosis will be much better for the future than it has been.

**9. Splenectomy for Carcinoma.**—Mary Smith states that only four cases of this operation are recorded. In her case the points of interest were: 1. The development of malignant ovarian tumors probably about her thirty-seventh year, during or following pregnancy. 2. A long period of good health after the removal of these tumors and the diseased appendix. 3. The entire disappearance of the sagolike growths observed at the first operation, and the appearance of a similar growth in the spleen, replacing the splenic tissue. 4. Reappearance of the

colloid growth in the abdomen after splenectomy, having originated from that part of the spleen where the growth had burst through the capsule. 5. Only slight variations in the blood before and after operation. 6. No symptoms pointing to any particular organ as the cause of rapid emaciation and loss of strength.

## AMERICAN JOURNAL OF OBSTETRICS.

January, 1908.

1. The Role of the Gonococcus in Disease, By R. W. TAYLOR.
2. The Treatment of Terminated Ectopic Gestation. Report of Cases, Including One of Recurrent Ectopic Gestation, By C. A. STILLWAGEN.
3. Extrauterine Gestation. A Clinical and Operative Study of Over One Hundred Cases, By L. J. LADINSKI.
4. Management of the Puerperium from a Surgical Standpoint, By A. FLINT, JR.
5. Care of the Patient in the Puerperium, By F. A. DORMAN.
6. Treatment of the Puerperium, By S. MARK.
7. In Memoriam, By W. H. S. WOOD.

## 1. The Role of the Gonococcus in Disease.—

Taylor summarizes his exhaustive paper on the gonococcus as follows: 1. It attacks the human urethra, causing catarrhal and hyperplastic inflammation, which may result in chronic arthritis and stricture. 2. It invades the testes and their appendages and thus threatens sterility in men. 3. Though usually limited to the subepithelial connective tissue it may invade the venous and lymphatic radicles of the male and female genitalia and cause local and general disturbance. 4. The whole organism may thus be attacked, with much resultant suffering and disability. 5. It may cause septicæmia, with serious or fatal result. 6. Arthritis and rheumatism are constant concomitants, causing marked changes in joints, tendons, bursæ, and muscles. 7. After generalized systemic infection the heart may become seriously involved. 8. The gonococcus may be destroyed by the antitoxic influence in the blood serum. 9. The microbe, or its toxins, may cause serious changes in the cerebrospinal system. 10. Invasion of the pleura may occur, with resultant phlebitis. 11. The spleen may be attacked. Evidence of liver involvement has not yet been demonstrated. 12. Many cutaneous and mucous membrane lesions may be caused by the gonococcus. 13. Bone lesions may result from its virulent action. 14. The entire genitourinary tract in the male may be involved. 15. The mouth, nares, rectum, umbilicus, and eyes may undergo inflammation from this cause. 16. Infection of the female genitals may menace life and health. 17. The possible production of an inhibitory serum is undetermined. 18. The gonococcus causes gonorrhœa in the majority of cases. 19. It may be latent, but may also at any time become potential. 20. It is capable of producing the most far-reaching infections to which human beings are susceptible.

## 5. Care of the Patient in the Puerperium.—

Dorman considers the selection of a proper nurse as a prime consideration in caring for a puerperal woman. Massage of the uterus for an hour after delivery should be a portion of the duty of the physician, not of the nurse. An abdominal binder is

advised and the patient should not be restrained from moving from side to side if she wishes to do so. The nurse must be scrupulously clean and not too fussy, while using all measures conducive to the comfort and safety of the patient. Fluid diet should be given for two days. The bowels should be moved with a mild laxative not later than the third day. Salines should be used if the breasts become engorged, and heavy breasts should be supported with a suitable binder. The baby should not be kept too long at the breast lest the nipple become macerated. An ice bag to the breast will sometimes avert inflammation. Wet dressings of aluminum acetate are recommended for cracked nipples, and a nipple shield may be used if nursing is painful. Careful bandaging of the breast is advised in cases in which it may be necessary to arrest the flow of milk.

9. Membranous Rhinitis, By F. A. ROSE.

## 3b. The Causes and Varieties of Urethral

Stricture.—Edmunds considers two groups of causes for stricture. In one, including the congestive stricture and the spasmodic stricture, there is temporary obstruction in the mucous membrane or in the muscular tissues surrounding the urethra; in the other, including organic stricture, there is structural narrowing in the urethral lumen. The congestive stricture is always due to gonorrhœa, and is marked by pain and sometimes by spasm. The spasmodic stricture is due to inhibitory action of the hypogastric nerve, which not only obstructs the urethra, but diminishes the contractile power of the bladder. Of the organic stricture traumatism of the urethra is frequently a cause, including incised wounds, injuries from falling, kicks in the perinæum, fracture of the pelvis, laceration by foreign bodies. The largest number of strictures include those which follow gonorrhœal inflammation. Congenital stricture is of rare occurrence and is due to faulty development in one or more of the three portions of the urethra. Finally the operation of prostatectomy is occasionally followed by a true stricture, which may be very troublesome.

3c. The Treatment of Stricture by Bougie.—Lett observes that in this method of treatment confidence, perseverance, and gentleness are of the great-

est importance. The urethra is so delicate and sensitive that rough treatment is not usually forgotten or forgiven. In passing the bougie one should not forget that most of the lacunæ and follicles in which an instrument is likely to be entangled are on the floor of the urethra, and that it is there that the majority of false passages occur. One is especially reminded of the point where the urethra turns up into the membranous portion through the triangular ligament. A false passage can usually be avoided by hugging the roof with the point of the instrument. Strictures vary greatly, not only in their form, but in their tolerance of treatment. Dilatation is the treatment which is to be recommended in the great majority of cases of urethral stricture. Urethrotomy should be resorted to for impermeable, resilient, nondilatable ones, and for those in which fever or rigor follows any attempt at dilatation.

**3d. The Treatment of Acute Gonorrhœa.**—Pardoe considers two methods, the abortive and the expectant, the choice of treatment, depending upon the limitation of the infection to the anterior urethra or its spread along the entire length of the canal. The abortive treatment is effective only in cases which are seen within a day or two after the appearance of symptoms and before the discharge becomes purulent. It consists in cleansing the urethra, determining the extent of infection with the urethroscope (after the application of a local anæsthetic), and then the free application to the urethra of a 2 to 4 per cent. solution of silver nitrate. This may be repeated, if necessary, in forty-eight hours. If the disease has passed the initial stage, urethral irrigation twice daily, for ten days, with a weak solution of potassium permanganate, will often prevent its further progress. In the expectant method of treatment cleanliness of the penis and urethra is imperative, antiseptic lotions and plain hot water being frequently applied. The diet should be simple, alcohol should be abstained from, and the urine should be made alkaline. When the pain and scalding of micturition are ended the balsams are indicated. Irrigation with permanganate of potash solution should be practised several times a week.

**9. Membranous Rhinitis.**—Rose thinks that, notwithstanding the frequent descriptions of this condition, it is frequently overlooked even by specialists in nose and throat disease. A bacteriological examination of a culture from the nasal membrane or the discharge will usually reveal many diphtheria bacilli. It usually occurs in children who may be in fair general condition, running from the nose, slight bleeding, and nasal obstruction being pronounced symptoms. The mucous membrane of the nose is congested and covered with a more or less dense and tough membrane. The pharynx is usually normal in appearance. The disease usually continues four to six weeks. The patient should be isolated as in well pronounced diphtheria, antitoxin should be injected, and the nose irrigated. Removal of the membrane by force does no good, as it will immediately reform. Though this is considered a mild form of diphtheria and should be treated as such, it will not communicate to a susceptible person diphtheria in a severe form, but only a similar rhinitis or a sore throat with a small patch of exudate.

## Proceedings of Societies.

### MEDICAL SOCIETY OF THE STATE OF NEW YORK.

*One Hundred and Second Annual Meeting. Held in Albany, January 27, 28, 29, and 30, 1908.*

The President, Dr. FREDERIC C. CURTIS, of Albany, in the Chair.

**Meeting of the House of Delegates.**—The minutes of the last meeting were read and approved and the roll called answered. The PRESIDENT then read his report, in which he said that the principal event of the year had been the passage of the new law regulating the practice of medicine, and that the profession as a whole owed much to the society, and the society, in turn, owed as much to its committee for its earnest efforts. He called attention to the excellent work of the society in protecting its members in malicious malpractice suits. He earnestly recommended the various county societies to increase their membership and thus increase that of the State organization. He recalled its primary object, namely, "to bring together all reputable practitioners of the State once a year," and referred to the fact that meetings of district branches had been held for the first time this year. He advocated cooperation instead of competition and the union of different districts in their scientific meetings. The business meetings of course must be held separately.

He advised that a committee be appointed to confer with a similar committee of the Bar Association to improve the present status of medical testimony, also that another committee be selected to continue the work in the matter of ophthalmia neonatorum.

For a century the meetings of this society had been held at this time and at this place (Albany), but the winter season was the worst of the year for physicians to convene, and Albany was not the geographical centre of the State. He asked if one permanent meeting place was really desirable. He recommended that the annual meetings be held in the fall and at different cities in the State each in its turn.

**The Report of the Secretary, Dr. WISNER R. TOWNSEND,** showed a total membership of 6,154 against 5,695 last year. During the past year the secretary had attended all the branch meetings but one, and spoke of the high order of scientific attainment shown. He referred to the great possibilities that this district branch system possessed, the value of the district branch presidents as delegates to the State organization, because he would be "aware of the local needs and conditions and of what should or should not be attempted." He urged each member of the society to try to bring in at least one physician who was not now a member. The secretary advised the county societies in the future to see that registration was properly kept up and so obliterate the unregistered list, recommended the State society to pay the expenses of its delegates to the national society, and suggested that the president be requested to send delegates to the meetings of societies of adjoining States.

**The Report of Dr. A. G. Root, Chairman of the Committee on Legislation,** showed that sixty-four bills had been introduced into the legislature last year, of which number eighteen had become laws.

Of the sixty-four, twenty-one were general medical bills, of these, fifteen died in committee, four became laws, and two did not receive the governor's signature. Three of the sixty-four were so called ice bills, referring to the gathering and sale of ice from polluted sources. All these bills died in committee. Eight of the sixty-four were labor bills, referring to the health of factory children and working women and the general hygiene of the working classes. Of these, two died in committee and six became laws. Seven of the sixty-four had reference to the tenement house legislation in New York city. Five died in committee and two were signed by the governor. Twenty-five of the sixty-four were bills relating to pharmacy, the sale of drugs, poisons, cocaine, etc. Of these, eighteen died in committee and seven became laws.

**Prize Essays.**—Dr. A. JACOB, chairman of the committee, reported that during the past year no essays had been presented.

**The Treasurer's Report,** by Dr. ALEXANDER LAMBERT, showed a surplus of \$10,717.30.

**The Committee on Public Health** recommended that a laboratory be equipped in each county seat for the examination of secretions and excretions, also that the State laboratory at Albany be enlarged and charged with manufacturing all the antitoxine and vaccine virus used by the State and that the State furnish this free of cost to those needing it, or at least at cost prices; also that the society actively cooperate with the State Department of Health in the passage and administration of a law for the reporting and registration of all cases of tuberculosis in the State. The committee called attention to the necessity of providing special hospitals for the care of the advanced cases of tuberculosis in every centre of population. It also commended the action of the State making it imperative to cease discharging raw sewage and other deleterious matter into streams or lakes or upon the land in the drainage area of streams or lakes that could pollute the waters used as a source of water supply.

**The President's Report** showed a decrease of twenty-five per cent. in the number of malpractice suits, and at the same time the number of paid up memberships in the society had increased. He said that the arrest in the number of malpractice suits was being speedily accomplished. For the past two years there had never been a single dollar received by plaintiffs in suits where the physician had asked of the society and received malpractice defense.

**The Special Committee on Meetings** recommended that the State be divided into four divisions, and that the State society meet in each of these four sections in its turn. This was referred to a committee, to report at the next annual meeting.

**Officers for the Ensuing Year** were elected as follows: President, Dr. Edward L. Trudeau; vice-presidents, Dr. A. G. Root, Dr. John Wheeler, and Dr. M. C. Hawley; secretary, Dr. Wisner R. Townsend; treasurer, Dr. Alexander Lambert; chairman

of the Scientific Committee, Dr. George H. Neuman; chairman of the Committee on Public Health, Dr. J. L. Heffron; chairman of the Committee on Legislation, Dr. F. Van Fleet; chairman of the Committee of Arrangements, Dr. W. J. Nellis; delegates to the American Medical Association, for one year, Dr. R. F. Weir, and Dr. Charles Jewett; for two years, Dr. W. R. Townsend, Dr. D. C. Moriarta, Dr. C. B. Angell, Dr. J. C. Bierwith, and Dr. Albert Vander Veer; alternate delegates for two years, Dr. Thornton, Dr. Brown, Dr. Little, Dr. Glass, Dr. Dunning, and Dr. Stover; alternate delegates for one year, Dr. J. A. Fordyce, Dr. A. H. Terry, Dr. W. T. Mulligan, Dr. C. G. Rossman, and Dr. Burrols. Mr. J. T. Lewis was reappointed the attorney for the society.

#### SCIENTIFIC SESSION.

**The President's Address.**—This was upon Questions of Broad Consideration Outside of Technique that Concern the Organized Medical Profession. He spoke of the significance of the annual meetings as the mirror of the year's attainments. He referred to the constantly changing methods of work and to questions of ethics, policy, and responsibility, as for the most part due to such gathering as the present one. He spoke of the value of organization, and said that, while the work done in the laboratory and college was of great importance, it was valueless until it was turned into the current of common life and passed along and became thereby a stream of influence helpful to humanity. As in the address to the delegates, he referred to the primary object of these meetings, "to associate all the reputable physicians of the Commonwealth and ostracize the unworthy." He urged that self respect, mutual improvement, and obligation to mankind be the actuating and animating motives of the society. He referred to the Medical Practice Law as the culmination of earnest and untiring efforts for the past twenty-five years and to democracy as the chief asset of the organization. He would bring every reputable practitioner in, simply drawing the line against those who for a very definite reason were thought unworthy, and so fulfill the purposes of the fathers. The organization, he believed, should take in all, give all a chance of expression, make its floor an open forum and its executive body as free as a New England town meeting; such an association of united men in county and State would always win good men to its membership and have its way so long as its purposes were high.

Obligation, the president stated, was the inevitable offspring of capacity, and it was his purpose to indicate how admirably this society was fitted for the work which devolved upon it. The public was dependent upon the medical profession, and the medical profession was apt to forget its obligation to the people. The people at large were more apt to obstruct than aid in the work for their safety. He emphatically condemned commercialism in medicine; called upon history to bear witness to the material value of sanitation, and pointed out how the mortality had been reduced one half in diphtheria and one third in diarrhoeal troubles. He viewed it as a function of this society to direct popular thought, create sentiment, establish county

health officers and laboratories, and recommend more teaching in sanitation, for sanitation must primarily come from the medical profession. He referred to the question of alcohol as one within the scope of the State organization, and believed it one of the most tremendous. Even its therapeutics he thought worthy of careful scrutiny. He also touched upon the still prevalent but also preventable disease ophthalmia neonatorum. He believed active work for its prophylaxis to be one of the obligations of the society. He lamented the present status of medicolegal testimony and said that measures were under way by means of which he hoped the present deplorable situation would be very much improved. In closing Dr. Curtis said: "But let us as a body of a learned profession never be unmindful of the fine old French motto, 'Rank imposes obligation.'"

**Nihilism and Drugs.**—Dr. A. JACOBI believed that a physician should be judged by his knowledge and not by his cures, and so bring medicine to the dignity of a science and not an art. He referred to the attitude of Oliver Wendell Holmes, who said: "It is not of the slightest interest to the patient to know if two or three cubic inches of his lung are hepatized," etc., and to the more modern William Osler, who advised students and physicians to be skeptical of the *Pharmacopæia* and counseled them to study people and learn to manage them, and said that it was the best doctor who knew the worthlessness of medicines. Dr. Jacobi expressed the belief that we owe much to the writings of Dr. Osler, but that we should be wary of all his sayings because of their widespread influence. He (Dr. Jacobi) wished that Dr. Osler had said: 1. Be critical of the *Pharmacopæia*. 2. He is the best doctor who knows the worth of medicines. 3. Study your fellow men and learn to serve them.

Dr. Jacobi then showed the impracticability of the one drug rule. He cited the "mixed treatment" of syphilis as a striking example of many drug methods. The cachexia could not be treated by any one drug, but by a union or combination of many, such as quinine, ergot, iron, etc. He urged practitioners not to treat the disease, but the man or woman. He then referred to the expectant as practised by many. He cited a case of spastic encephalitis in which a specialist was called in and said: "Let me see her in six months." He, being called in subsequently, advised potassium iodide, massage, hydrotherapy, etc., and the child was greatly improved in six weeks. Thus the actual treatment of a month with drugs had proved superior to the expectant treatment of six months.

He regarded the expectant treatment as a sin of omission which frequently arose to the dignity of a crime. It was apt, in his opinion, to render men callous. The expectant treatment of diphtheria was cited as being especially bad, and drugs, vigorous stimulation with alcohol, and local antiseptics were strongly advocated.

As to drugs, he believed cardiac stimulation by means of digitalis, strophanthus, sparteine, strychnine, ammonia, and musk indispensable in the heart failure of pneumonia, and they often were really life saving. He urged large doses when required. As to the dose for any particular age, he recommended

giving as much of a remedy as the case demanded. He considered the injection of morphine over the seat of pain better than into the arm, but also deemed it far better in the arm than in the stomach. Contrary to the general opinion, Dr. Jacobi believed opium to be well borne by children, because of their indolent nervous systems due to lack of higher development. Belladonna, too, must be given in full sized doses to obtain the best results.

The speaker believed no case of chronic tuberculosis properly treated unless guaiacol was used. Whether it acted upon the stomach, improving and stimulating it, or antagonized the toxine was as yet unknown, but it did give good results.

In concluding, he referred to Germany as being the source of much that was good in medicine, but also of much that was bad.

(To be continued.)

## Letters to the Editors.

### ACUTE POLIOMYELITIS.

COLONIAL BUILDING,  
BOSTON, January 15, 1908.

To the Editors:

The State Board of Health of Massachusetts has begun investigations into the etiology, course, and treatment of acute poliomyelitis following the accounts of the recent epidemic of this disease in New York City.

If I had clinical material at hand I would carry out some experiments to determine positively the correctness of my theory that this is an air borne infection whose port of entry is naturally the first tonsil.

As I have proved to the satisfaction of many, both patients and physicians, that this is true of many other air borne infections, such as acute articular rheumatism, scarlet fever, diphtheria, influenza, etc., and that local and direct treatment made at this site of infection is always positive in results, I am ready to affirm and would respectfully suggest that, instead of standing helpless by the afflicted patient, we should attack the disease, which is an infection, *in situ*.

Seibert, recently writing of the prophylaxis of meningitis, advises that the nasopharynx be thoroughly sterilized locally.

His evidence had been drawn from reports of autopsies in which the course of the infection with the meningococcus was traced from the postnasal space to the meninges. The process of treatment is so simple and so direct that it may be readily made by any one skilled in treating the nose or the ear. It is preferable to make the applications through the nose.

EDMUND D. SPEAR.

### THE ETIOLOGY OF BERIBERI.

PITTSBURGH, PA. January 11, 1908.

To the Editors:

Apropos of your editorial article in the *Journal* for January 18th on the subject of the etiology of beriberi, I beg leave to call attention to a report published in the *Annual Report of the Surgeon-General, Surgeon General of the U. S. Marine Hospital Service*.

vice for the Fiscal Year 1897, on the occurrence of beriberi aboard vessels trading with the ports of the United States on the Gulf of Mexico.

While at the Gulf Quarantine Station I saw cases of beriberi aboard ship and was called upon to make inquiries as to the circumstances attending the origin of the disease. From the inquiries which I made in that instance I was forced to the conclusion that the beriberi which I was investigating was a dietetic disease entirely, and no other explanation seemed possible; and I was impressed most of all with a suggestion made to me by the master of a vessel, who said that he had never seen the disease until canned foods were introduced on shipboard. The canned goods used were often bargain lots which the vessel had picked up at some port at a very low price, and in such a case it is to be suspected that the goods were such old stock that the merchant had to dispose of them as best he could.

It was suggested, in the report above referred to, that the beriberi as seen at that time was due either to a chronic ptomaine poisoning or to chronic poisoning with a metal, dissolved by a slow process from the cans, in tinned goods.

A. C. SMITH,  
Surgeon, U. S. P. H. & M. H. S.

### Book Notices.

*A Textbook on the Practice of Medicine.* By JAMES M. ANDERS, M. D., Ph. D., LL. D., Professor of Medicine and Clinical Medicine at the Medicochirurgical College, Philadelphia, etc. Illustrated. Eighth Edition, Thoroughly Revised. Philadelphia and London: W. B. Saunders Company, 1907. Pp. 1317. (Price, \$5.00.)

When a medical work has reached the dignity of an eighth edition its rank and usefulness have been sufficiently demonstrated and the task of the reviewer is an easy one. The qualities which have distinguished previous editions of Dr. Anders's well known textbook, orderly arrangement of material, evincing wide familiarity with the latest literature, nice discrimination in diagnosis, good judgment in recommendations as to treatment in which hygiene and diet receive due consideration, and a concise, pleasing literary style, are all apparent in this volume. Many of the chapters have been practically rewritten to keep pace with recent advances in internal medicine. The sections showing the largest amount of such revision are perhaps those relating to the tropical parasitic diseases. Among the new subjects discussed are the aplastic anemia of Senator, splenomegaly, the Stokes-Adams syndrome, Vincent's angina, chronic appendicitis without acute attacks, and intestinal autointoxication. Both lobar pneumonia and acute articular rheumatism are definitely placed in the group of general infectious diseases. Accepting the *Treponema pallida* of Schaudinn, syphilis is classified with the animal parasitic diseases along with infection with trichina, tenia, echinococcus, and the trypanosomes. The author's sparing use of illustrations is to be commended. Where they are introduced they really serve to elucidate the text, and are not used merely for the purpose of making a book prettier. The book is a masterpiece of practical observation and

the great masters of clinical teaching, and is further enriched by the author's large personal experience. The present edition is in every way a very satisfactory statement of the internal medicine of to-day, and will be received with the favor which has been accorded the preceding editions.

*Diseases of the Larynx.* By HAROLD BARWELL, M. B. (Lond.), F. R. C. S. (Eng.), Surgeon for Diseases of the Throat, St. George's Hospital; Laryngologist, Mount Vernon Hospital for Diseases of the Chest, etc. London: Henry Frowde and Hodder & Stoughton, 1907. Pp. viii+266.

*Diseases of the Nose.* By E. B. WAGGETT, M. A., M. B., B. C. (Cantab.), Surgeon to the Throat and Ear Department of the Charing Cross Hospital, etc. London: Henry Frowde and Hodder & Stoughton, 1907. Pp. xii+282.

*Diseases of the Ear.* By HUNTER TOD, M. A., M. B., B. C. (Cantab.), F. R. C. S. (Eng.), Aural Surgeon to the London Hospital, Lecturer in Aural Surgery at London Hospital Medical College, etc. London: Henry Frowde and Hodder & Stoughton, 1907. Pp. xiv+317.

These little manuals are hardly designed to replace any of the standard textbooks, yet each of them contains something of interest, and all are worth reading by those who already know the subject and can appreciate an original presentation of familiar facts. Barwell has an excellent chapter on the examination of the larynx, and others on points of treatment which are valuable. The book is concise and practical, the rarer forms of disease and theoretical aspects of the subject being treated of briefly. Waggett's pages, as he says, are intended to be read as they were written, rapidly, from cover to cover. He gives a good account of the embryology and comparative anatomy of the nose and a number of excellent chapters, such as those on adenoid facies, local treatment, and others. Tod writes specially for those who have not had the opportunity of devoting much time to the study of diseases of the ear, but his summary will undoubtedly be of service in many ways to the more experienced practitioner. The diagrams showing modes of extension of inflammation from the tympanic cavity, and the cuts illustrating the intracranial otitic complications, are particularly instructive and novel.

*Die Salzsäuretherapie auf theoretischer und praktischer Grundlage.* Bearbeitet von Prof. Dr. HANS LEO in Bonn. Berlin: August Hirschwald, 1908. Pp. 138.

Professor Leo, of Bonn, has made the hydrochloric acid therapeutics the subject of a very interesting little book. Hydrochloric acid, as is well known, is a compound which is not foreign to the body; that means, it is found normally in man, and plays an important rôle in digestion. It is, therefore, necessary to first study the secretion of the stomach under normal and pathological conditions, its influence upon the food, and its physiological action on the stomach and intestines, so as to give hydrochloric acid treatment its proper place in pharmacology, and thus to find out its pharmacodynamic properties. This, in short, is the disposition of the subject the author has made in his book. He also refers to the poisonous properties of hydrochloric acid, and gives a full review of the practical subject of its therapeutics. Very interesting and to the point are his conclusions.

*Ophthalmia Neonatorum*, with Especial Reference to its Causation and Prevention. (The Middlesex Prize Essay of the British Medical Association, 1907.) By SYDNEY STEPHENSON, M. B., C. M., Ophthalmic Surgeon to Queen Charlotte's Hospital, London, etc. London: George Pulman & Sons, Limited, 1907. Pp. 258.

Stephenson's work is a complete historical and medical study of a subject which, for practical importance, must appeal not only to the oculist and obstetrician, but to all physicians who are interested in the achievements and the possibilities of hygiene and preventive medicine. The ætiology and bacteriology, the symptoms, prognosis, and treatment of gonorrhœal infection of the eyes of the new born, are discussed at length, on the basis of the author's own experience and on that of an unusually thorough and complete study of the literature. The economic side of the question and the relation of the State to preventive measures are also brought out. The statistical tables are numerous and will be of great value to future workers in this field. Stephenson, in conclusion, repeats the admonitory words of Hermann Cohn, "Die Blennorrhœa neonatorum kann und muss aus allen civilisirten Staaten verschwinden."

*A Manual of Orthopaedic Surgery.* By AUGUSTUS THORNDIKE, M. D., Assistant in Orthopedics at the Harvard Medical School, Visiting Surgeon to the House of the Good Samaritan, etc. With 191 Illustrations. Philadelphia: P. Blakiston's Son & Co., 1907. Pp. 401.

Dr. Thorndike has compiled a very handy and practical manual. The book is divided into five parts. Part I treats of the foetal deformities and errors of development of the skeleton and the nervous system, and the accidents at birth. Part II comprises deformities due to the action of external forces on growth. In Part III are discussed the diseases and injuries of bones and joints in postnatal life. Part IV gives the deformities from acquired diseases of the nervous and muscular systems. In Part V is described the technique of plaster of Paris appliances and apparatus.

From this short synopsis of the contents it can be seen that the author has given his subject a thorough treatment.

#### BOOKS, PAMPHLETS, ETC., RECEIVED

*Diseases of the Heart.* By Professor Th. v. Jürgensen, of Copenhagen, Professor L. v. Schrotter, of Vienna, and Professor E. Kriebel, of Grafswald. Edited with Additions by GEORGE DOCK, M. D., Professor of Theory and Practice of Medicine and Clinical Medicine, University of Michigan, Ann Arbor. Authorized Translation from the German, under the Editorial Supervision of ALFRED STENDEL, M. D., Professor of Clinical Medicine in the University of Pennsylvania. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 848.

*Essentials of Modern Electrotherapeutics.* An Elementary Textbook on the Scientific Therapeutic Use of Electricity and Radiant Energy. By Frederick Finch Strong, M. D., Instructor in Electrotherapeutics at Tufts College Medical School, Boston. New York: Rossmore Company, 1908. Pp. 8, 112.

*Maternity.* By Henry D. Fry, M. D., Sc. D., Professor of Obstetrics, Medical Department of the Georgetown University, etc. New York and Washington: Neale Publishing Company, 1907. Pp. 220.

*The Preservation of Life.* Optimums. Sonder. By LEO METCHNIKOFF, Subdirector of the Pasteur Institute, Paris. The English translation edited by P. Chalmers Mitchell, M. A., D. Sc. Oxon., Hon. LL. D. F. R. S., Secretary of

the Zoological Society of London, etc. New York and London: G. P. Putnam's Sons, 1908. Pp. xx-343.

*Formulaire synthétique de médecine.* Par le Dr. L. Pron. Paris: Jules Rousset, 1908. Pp. 601.

*Transactions of the American Ophthalmological Society.* Forty-third Annual Meeting, Washington, D. C., 1907. Volume XI, Part II. Published by the Society.

#### Miscellany.

**The Controversy between Surgeon General Rixey and Admiral Brownson.**—The *Army and Navy Journal* publishes the following letter, sent by Surgeon General Rixey to the Secretary of the Navy, dated January 22, 1908. As this letter covers the controversy, we publish it in full:

Admiral Brownson's written representations in regard to the hospital ship have just been brought to my attention, and as they are of such a character as to lead to serious misunderstanding of the matter without further explanation, the Bureau begs to submit the following statement in answer thereto, and respectfully requests that the same be transmitted to Congress in connection with the other papers called for by the resolution:

First. I have never asked that medical officers be entrusted with the navigation of hospital ships. On the contrary, I have asked that under the Bureau of Navigation a sailing master and crew be selected and held responsible for the navigation and care of the ship. All orders to and from the sailing master should pass through the senior surgeon, who will be in command. I asked for the medical officers of the navy exactly the same status as was and is given to the medical officers of the army on hospital ships. The ship now in question, the *Relief*, as a hospital ship, was commanded by medical officers of the army. There can be no question but that the medical officer of the navy is as well qualified for this work as is the medical officer of the army.

Second. The neutrality of the hospital ship demands that line officers and a fighting crew should not be put aboard her except when on the sick list, when they are a part of the medical corps until discharged from the sick list and from the hospitals or hospital ship.

Third. I agree with Admiral Brownson that the pilot age, navigation, and handling of the hospital ship should be as well done as is that of any other ship, but I contend, and the facts show, that all of this has and can be done as efficiently by a merchant master and sailors as by a line officer and a fighting crew. For example, see Admiral Brownson's statement in regard to auxiliaries and the history of the transports run by the army at present and in past wars. Admiral Brownson, citing the difficulties encountered in the navy with different types of crews, states: "As a result of experience with the various systems, all in force at the same time and under similar conditions, officers who have had experience with the naval auxiliaries agree that the most efficient organization is obtained when these vessels are commanded by a full naval crew, and it is only the fact that at present there is such a shortage of officers and men that naval auxiliaries are not so commanded." In reply to this I wish to call your attention to the fact that line officers and naval crews would jeopardize or destroy neutrality in time of war, and moreover, every fighting man of the navy will be needed for our fighting ships in war. And still further, I wish to submit that a naval crew who would wish to be on a hospital ship when there was fighting to be done, would, as in the case of the *Relief*, be most inefficiently and unreasonably used in the fighting branch.

Fourth. Admiral Brownson refers to orders issued and difficulties encountered in the navy with civilian crews and masters, and specially cites the cases of the *Iris* and *Nausen*. The army transport service is noted for its efficiency, and it is navigated by a civilian crew and master without a bureau of navigation to select and equip. How much better crews should be made such arrangements. In the case of the *Iris*, she was not saved by a line officer who was on board, and she was not protected. But the matter does

missed, as he should have been. In the case of the *Nansen*, cited by Admiral Brownson, the second officer on board, who was drunk and disorderly, if she had been a hospital ship would have been treated as an insane patient, and he would have been locked up promptly until he could have been dealt with under regulations governing such cases.

Fifth. In regard to command in our shore hospitals and hospital ships, there can be no question as to the medical officers having all the authority necessary to enforce their commands. Such authority is exercised every day in all of our hospitals on shore over line officers and enlisted men so long as they are on the sick list and in the hospital; also over civilian employees and all that come into the hospitals; in other words, we absolutely command in our hospitals ashore. This question was settled by order of the Department in S. O. dated August 22, 1904, and it was opposed just as earnestly by the Bureau of Navigation as is now our present request in regard to command of our hospital ships. This bureau has found that this sustaining of the bureau in regard to command in the shore hospitals has been most satisfactory, and just here I wish to bring out clearly that we are exercising the right of command according to law in our own corps, and Admiral Brownson's contention that a line officer on the sick list in a hospital ship does not belong to that corps is not well taken. If a line officer sick in our hospital or on a hospital ship is not under the authority of the medical officer in command, he would be a most dangerous person to put in a hospital or aboard the hospital ship. He might be out of his head or insane; and as long as he is on the sick list, it is absolutely necessary that he should be under the control of the medical officer, and there has been no question of this in the past, in my thirty odd years in the navy. A patient going aboard the hospital ship remains on the sick list until he is discharged from that ship, and during this time he is absolutely under the control of the medical officer in charge.

Sixth. The Navy Regulations would be the same on the hospital ships as in any of our hospitals ashore, and in any other portion of the navy, and punishment for the infraction of discipline would be just the same and according to regulations. There is no question of the control of the paymasters now serving under medical officers in our hospitals, nor of the enlisted force. Why should Admiral Brownson fear for the control of them on a hospital ship? In conclusion, Admiral Brownson refers to the *Solace*, the only hospital ship mentioned by him, and the only one that he can find that was ever commanded by a line officer, whereas I have cited a number of them in our own and in foreign services which have been commanded by medical officers. The *Solace*, as I have already cited, destroyed her claims to neutrality on several occasions, and even laid claim to prize money for having taken part in offensive operations. The importance of this contention of Admiral Brownson does not stop with the hospital ship. In order to have an efficient personnel selected to watch over and ever ready to man the guns of our navy and handle our fighting ships, with the assurance that when our men are cut down they will be cared for, it is necessary that the medical officers must have authority in their own corps, and further, that medical officers' authority must be recognized in all matters of sanitation. There is no question of it ashore, and has not been since 1904, although the line fought just as hard to prevent the use of the word "command" in our hospitals ashore as it is fighting now to prevent the use of the word "command" in our hospital ships at the present time. In conclusion, I have to submit that the hospital ship would be run according to regulations as laid down a year ago by the Secretary of the Navy, and this should be done in time of peace and tried to the satisfaction of the Department and the country, so that in time of war the medical officers may know where they stand in the care of the thousands that may be entrusted to their care.

**The State Charities Aid Association.**—The State Charities Aid Association, which for thirty-five years has visited the public charitable institutions of the State and endeavored in many ways to secure their improvement, has turned its attention to the question of the causes of dependence upon the pub-

lic. At a meeting of its board of managers, held last May, the following preambles and resolutions were adopted:

Whereas, Pulmonary tuberculosis is one of the leading causes of illness and death, and, therefore, of suffering, destitution, and pauperism, in this State; and,

Whereas, Recent discoveries in medical science and recent experience in the administrative control of tuberculosis have made it possible to take practical and effective measures for the restriction of this disease; and,

Whereas, Effective work in this direction has been carried on for several years in this city by the tuberculosis committee of the Charity Organization Society, and is not carried on as a rule elsewhere in the State; therefore,

Resolved, That it is desirable, if sufficient funds therefor should become available, without impairing the income of the association for work to which it is already committed, that the association should take it up actively, through its county committees, with the aid of a paid secretary, the promotion of measures for the restriction of tuberculosis in the State, outside of New York City.

A substantial contribution having been made available for this work, the association engaged the services on October 1st of Mr. John A. Kingsbury, a graduate student at Columbia University, on leave of absence from the position of principal of a public school in Seattle, Wash. The State Department of Health has established during the past summer a traveling tuberculosis exhibit, and the work of the State Charities Aid Association and of the State Health Department is being conducted in close co-operation, the association aiming to secure the largest practical results from the interest aroused by the exhibit. With Mr. Kingsbury's aid the Oneida County committee of the State Charities Aid Association has taken up most actively the antituberculosis campaign in Utica, where the tuberculosis exhibit has been shown for the past two weeks. At a public meeting there, addressed by Colonel William Cary Sanger, president of the New York State Branch of the National Red Cross; George F. Canfield, vice president of the State Charities Aid Association; Homer Folks, secretary of the association; Hon. Eugene H. Porter, M. D., State commissioner of health, and Dr. Livingston Farrand, secretary of the National Association for the Prevention of Tuberculosis. Governor Hughes, who had been invited to address the meeting, sent a cordial letter, regretting his inability to attend and expressing his deep interest in the movement. A committee on the prevention of tuberculosis has been appointed by the local branch of the State Charities Aid Association, Dr. William M. Gibson, of Utica, is chairman of the committee. A comprehensive program of constructive measures has been adopted by this special committee as a basis for its work. The establishment of a tuberculosis free dispensary and the services of a visiting nurse for a year are already assured. The Health Department has passed resolutions looking toward the establishment of a system for the registration of cases of tuberculosis. Very great interest has been shown by the citizens of Utica in the ex-

hibit, which was visited by 4,000 persons in the course of the fortnight. The outlook for carrying into effect a comprehensive program is most favorable. From Utica the exhibit was sent to several cities in the State and finally to New York City.

**Luke the Physician.**—Professor Adolph Harnack, of the University of Berlin, who is known as one of the most distinguished of living critical historians of the period at the beginning of the modern era, has occupied himself not a little with various points of medical history. He is considered an authority on such matters of philology as throw light on the details of the history of Greek and Roman medicine. His historical writing has been taken up much more, however, with investigation of Christian origins than with medical matters. It happens, however, that his last book (*Luke the Physician*, translated by J. R. Wilkinson, M. A., New York: G. P. Putnam's Sons, 1907) is one that unites both these subjects, and competent critics have declared it to be one of the most interesting contributions to history of recent times. While in recent years some doubt has been expressed as to the authorship of the writings formerly attributed to Luke, and even more doubt as to the tradition that their author was a physician, Professor Harnack has declared his conviction of the truth of both of these points and gives incontrovertible arguments for them. These arguments are drawn chiefly from the words and expressions which are used in the original version of the writings attributed to Luke. Careful investigation of the vocabulary and style of the author show that the tradition as to his being a physician is true beyond all doubt. The language of these writings betrays inevitably the tongue and the mind of one familiar with the Greek medicine of the time. Attention has frequently been directed to this before, but never with so rich a wealth of illustration and erudition as on this occasion. As has been well said, the argument from philology has never received such skillful treatment as is given it by Harnack. It seems probable, then, that physicians who are interested in this earlier history, especially from its medical aspects, may still continue to cherish the old tradition, according to which one of their number was in that olden time an active factor in the introduction of the ideas of the fraternity of the human race into the world which took place some 1900 years ago.—From the *Journal of the American Medical Association*, November 30, 1907.

The "Cruise of the U. S. S. *Æsculapius*, an Opera in One Act," was the title of the special entertainment provided for the guests at the annual dinner at the Gridiron Club, held in Washington on January 25th. This club, composed largely of newspaper correspondents stationed in Washington, has achieved a worldwide reputation owing to the character of entertainments furnished at its dinners, which consist of skits or satires based on current political topics. The controversy regarding the command of hospital ships furnished the basis of entertainment this year. Among the guests at the dinner were the President, the Vice President, the Speaker of the House of Representatives, and many members

of the diplomatic corps and high officials in Washington. Sailors dressed in regulation uniform explained that they were part of the crew of the "good ship *Æsculapius* recruited from the Georgetown Medical College." One of the characters, "Admiral Trixey," informed the audience to the tune of an air from "Pinafore" that

When I was a lad I served a term  
As an office boy to an apothecary's firm.  
I filled prescriptions so carefulee  
That now I'm an Admiral  
In the new Navee.

Another character reported to the captain of the *Æsculapius* singing:

Kind captain, I've important inflammation;  
Sing hey, the merry doctor and the tar.

Another character, when asked what orders he had received, said he had received no orders, but had been given several prescriptions.

## Public Health and Marine Hospital Service:

*Official list of changes of stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the seven days ending February 1, 1908:*

- BROOKS, S. P., Acting Assistant Surgeon. Granted leave of absence for seven days from January 25, 1908, under paragraph 210, Service Regulations.
- BRYAN, W. M., Assistant Surgeon. Granted leave of absence for seven days, to be taken *en route* between Savannah, Ga., and New Orleans, La.
- FRANCIS, EDWARD, Passed Assistant Surgeon. Granted leave of absence for seven days.
- LLOYD, B. J., Passed Assistant Surgeon. Granted leave of absence for seven days from December 21, 1907, on account of sickness.
- MCCOY, G. W., Passed Assistant Surgeon. Directed to proceed to Sussex County, Va., via Richmond, Va., for special temporary duty; upon completion of which to rejoin his station at the Hygienic Laboratory, Washington, D. C.
- MANNING, H. M., Assistant Surgeon. Relieved from duty in the Philippine Islands and directed to return to the United States, reporting by wire his arrival in San Francisco.
- MATHEWSON, H. S., Passed Assistant Surgeon. Granted leave of absence for seven days from January 31, 1908.
- ROBERTSON, H. MCG., Passed Assistant Surgeon. Relieved from duty at Reedy Island Quarantine Station and directed to proceed to Tampa Bay Quarantine, assuming command of the Service.
- RODMAN, J. C., Acting Assistant Surgeon. Granted leave of absence for four days from January 28, 1908.
- STONER, G. W., Surgeon. Granted leave of absence for six days from January 18, 1908, under paragraph 189, Service Regulations.
- THORNTON, M. J., Acting Assistant Surgeon. Granted leave of absence for one day on account of sickness.
- YOUNG, G. B., Surgeon. Detailed to represent the Service at the meeting of the Fourth Annual Conference of the Council on Medical Education, American Medical Association, to be held at Chicago, Ill., April 13, 1908.

## Army Intelligence:

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending February 1, 1908:*

- BAKER, FRANK C., Captain and Assistant Surgeon. Upon arrival at San Francisco, Cal., will proceed to Fort Oglethorpe, Ga., for duty.
- COLE, CLARENCE LER., First Lieutenant and Assistant Surgeon. Granted three months' leave of absence, to take effect when relieved from duty at Jefferson Barracks, Mo.
- CULLER, ROBERT M., First Lieutenant and Assistant Surgeon. Leave of absence extended one month.
- HALLOCK, H. M., Major and Surgeon. Having been found incapacitated for active service, is retired, to take effect March 20, 1908; granted leave of absence to that date.
- JUENEMANN, GEORGE F., First Lieutenant and Assistant Surgeon. Upon arrival at San Francisco, Cal., will proceed to Fort McDowell, Cal., for duty at the Depot of Recruits and Casuals.
- KRIEGER, CHARLES F., Major and Surgeon. Relieved from further duty with the Army of Cuban Pacification; ordered to report in person to Brigadier General Frederick Funston, president of an Army retiring board at San Francisco, Cal., at such time as he may designate, for examination by the board.
- PALMER, F. W., First Lieutenant and Assistant Surgeon.

SHORTLIDGE, E. D., First Lieutenant and Assistant Surgeon. Upon arrival at San Francisco, Cal., will proceed to Fort Du Pont, Del., for duty.

## Navy Intelligence:

*Official list of changes in the medical corps of the United States Navy for the week ending February 1, 1908:*

- BIDDLE, C., Medical Inspector. Commissioned a medical inspector, from June 16, 1907.
- BROWNELL, G. DEW., Surgeon. Detached from the naval training station, Newport, R. I., and ordered to the *Mississippi*.
- DESSEZ, P. I., Passed Assistant Surgeon. Commissioned a passed assistant surgeon, from June 10, 1907.
- DONELSON, M., Assistant Surgeon. Detached from the *Stringham* and ordered to the *Porter*.
- MCDONELL, W. L., Passed Assistant Surgeon. Commissioned a passed assistant surgeon, from September 19, 1907.
- MACKENZIE, E. G., Assistant Surgeon. Ordered to the Naval Hospital, New York, N. Y.
- PORTER, F. E., Passed Assistant Surgeon. Commissioned a passed assistant surgeon, from June 7, 1907.
- RUSSELL, A. C. H., Medical Inspector. Commissioned a medical inspector, from May 7, 1907.
- SCHMIDT, L. M., Assistant Surgeon. Ordered to the Naval Hospital, Annapolis, Md.
- SELLERS, F. E., Assistant Surgeon. Detached from the Naval Hospital, Annapolis, Md., and ordered to the Naval Academy.
- VICKERY, E. A., Passed Assistant Surgeon. Commissioned a passed assistant surgeon, from October 11, 1907.
- WHITESIDE, L. C., Acting Assistant Surgeon. Ordered to the Naval Hospital, Newport, R. I.

## Births, Marriages, and Deaths.

## Married.

- FLOYD—MANLEY.—In Jacksonville, Florida, on Saturday, January 18th, Dr. George M. Floyd and Miss Clara J. Manley.
- PERCIVAL—MCBURNERY.—In Philadelphia, on Tuesday, January 21st, Dr. Milton Frazer Percival and Miss Mary Beatty McBurnery.
- RAGUEL—MATLACK.—In Lewisburg, Pennsylvania, on Wednesday, January 29th, Dr. George Earle Raguel, of Philadelphia, and Miss Mary Matlack.
- Died.*
- ARNOLD.—In Philadelphia, on Saturday, January 25th, Dr. John P. Arnold, aged forty years.
- BATES.—In Canaan Four Corners, New York, on Sunday, January 26th, Dr. Milford L. Bates, aged sixty-two years.
- BRUMBAUGH.—In Huntington, Pennsylvania, on Monday, January 27th, Dr. A. B. Brumbaugh, aged seventy-two years.
- BUCK.—In Springfield, Illinois, on Thursday, January 23d, Dr. Horatio B. Buck, aged seventy-five years.
- FAGER.—In Harrisburg, Pennsylvania, on Friday, January 24th, Dr. Charles B. Fager, aged sixty-five years.
- GRIFFITHS.—In New York, on Friday, January 31st, Dr. John J. Griffiths, aged forty-eight years.
- KRAUSI.—In Brooklyn, on Friday, January 31st, Dr. William J. Krausi, aged forty-nine years.
- MARSTON.—In Lightfoot, York County, Virginia, on Sunday, January 26th, Dr. Thomas P. Marston, aged seventy-three years.
- OGG.—In Hillsboro, Virginia, on Thursday, January 23d, Dr. Charles C. Ogg, aged thirty years.
- PECKE.—In Rotterdam, New York, on Monday, January 27th, Dr. Charles Sample Pecke, aged forty-three years.
- REED.—In Philadelphia, on Saturday, January 25th, Dr. John A. Reed, of Maysville, Kentucky, aged sixty-four years.
- RILEY.—In Omaha, Nebraska, on Friday, January 31st, Dr. A. W. Riley.
- SIZER.—In Brooklyn, on Monday, January 27th, Dr. Nelson Buell Sizer, aged sixty-three years.
- STEINMETZ.—In Baltimore, Maryland, on Sunday, January 26th, Dr. William R. Steinmetz.
- THOMAS.—In Quakertown, Pennsylvania, on Tuesday, January 26th, Dr. Joseph Thomas, aged seventy-eight years.

#### ON SOME POINTS REGARDING URETHROPLASTIC OPERATIONS, WITH SPECIAL REFERENCE TO THE DISLOCATION METHOD.\*

By CARL BECK, M. D.,  
New York,

Professor of Surgery in the New York Postgraduate Medical School and Hospital; Visiting Surgeon to the St. Mark's Hospital and the German Poliklinik.

Dislocation of the urethra for hypospadias, some types of epispadias, or other urethroplastic operations are of a more or less delicate nature, especially so in the case of children. Delicate operations require delicate instruments, and those commonly used do not, in my experience, answer this desideratum.

A thumb forceps, as generally used, may tear the urethral membrane of a child. The retractors holding the reflected skin flaps must hold the tissues without injuring them. The knives for dissecting out the urethra, as well as the bistoury used to perforate the glans, must be of a special and delicate construction.

I therefore requested the Kny-Scheerer Company to construct for urethroplastic operations a special set of instruments containing all that are needed for that purpose, viz.: A small, short scalpel for the dissection of the urethra from its bed, a long bistoury for the perforation of the glans or the penile substance, two toothed thumb forceps, delicate blunt scissors curved on the flat for blunt dissection, a toothed retractor, two specially adjustable holding forceps which may serve as retractors at the same time, two small elastic artery clamps, various thin needles (sharpened on both sides up to the eye), a special needle holder, and a rubber catheter provided with a perforated shield. This set may also be utilized for other delicate plastic operations.

As a rule, my operation for dislocating the urethra is started by introducing a thick rubber catheter into the urethra. As soon as the catheter has reached the bladder, its opening is temporarily closed. Now a silk suture is carried through the perforated shield of the catheter or through the wall of an ordinary rubber catheter, as well as the abnormal orifice, with a thin curved needle, as described. The suture, after being knotted, is left long, so that it may be utilized later for fastening the urethral orifice at the tip of the glans. By pulling the catheter slightly the urethra is stretched to such a degree that the incision can be made with a greater amount of security and in the straight direction. If a small, sharp bistoury is inserted at the tip of the glans, contracture need not

exerted, which facilitates the process of lifting the urethra from its bed.

In this position the backward dissection of the integumental flaps, which are meant to cover the dislodged urethral portion, is also made easier.

For isolating the urethra the catheter serves not only as a handle, but also as a guide. It can easily be palpated through the urethral wall—in children it can even be seen through the somewhat translucent urethral wall. Thus, the surgeon is warned against incising it. To serve the catheter as a strong hold, the orificial portion of the urethra should remain as thick as possible. If there is any tension the sutures at the tip of the glans are supported by placing a relaxation suture of finest catgut at each side of the urethral wall near the sulcus.

In one of the extreme cases of scrotoperineal hypospadias I have modified my method of creating a new urethra by deep incisions at each side of the penis, parallel to the existing groove (See *New York Medical Journal*, December 8, 1900), in the following way:

After introducing the catheter through the abnormal orifice (Fig. 1) the urethra was dissected backward and freed as far as possible. Enveloped in sterile gauze the dissected urethral portion hung down, pulled by the weight of the forceps, which closed the opening of the catheter. After the amount of tissue needed for forming a urethral tube of sufficient length was measured, a flap of proper proportion was shelled out from the posterior surface of the penis. Fortunately there was a preformed gutter lined with the rudiments of a mucous membrane. Where the base of the dislocated urethral fragment joined the lower end of the gutter, the incisions were made especially deep, so as to secure voluminous tissue for better nutrition of the flap, which was severed from its connection near the glandular portion of the penis and isolated backward. The whole dissected gutter, which was in broad connection with the region of the abnormal orifice, was now folded together over the rubber catheter and thus transformed into a tube which was circularly united with the tip of the dislocated urethral fragment. The penis was then perforated in its whole extent by a double edged bistoury, forming an artificial orifice at the tip of the gland similar to my ordinary procedure for glandular or penile hypospadias. Through this newly formed canal the flap, together with the dislocated urethral portion still containing the catheter, were pulled and fastened at the tip. The bistoury must make free excursions by its perforation of the penile tissue in such cases in order to obtain sufficient space for the formation of the preformed tube. At the point of junction between the bridge of the flap and the orifice of the urethral fragment too much pulling must not be tried, because the nutri-

FIG. 1.—Scrotoperineal hypospadias before operation.

trition of the bridge may suffer. Of course the defect left at the outer surface is covered by a flap taken from the scrotum. The anterior portion of a by the urethral fragment further back, there is a sufficient amount of propelling power present.

A decided advantage of this procedure is the post-urethra of this kind is not an ideal one, since it lacks the elasticity of a normal urethra, but, being aided

the ability of utilizing the mucous membrane of the pre-formed gutter for a urethra. Its disadvantage, on the other hand, is the mutilation of the penis within

FIG. 3.—Gauze strip fastened to penis with two sutures.

the extent of the grooved flap. To avoid this, I have in another case of the same nature taken the flap from the scrotum right below the abnormal orifice, obtaining a perfect result in a boy of seventeen years of age. There the abnormal orifice was circumcised after the introduction and fastening of the catheter. Then the latter was held up against the abdomen in order to get it out of the field of operation. Now an

FIG. 4.—Final fastening of retained gauze strip.

incision was made at each side of the raphe and parallel to it to the extent of an inch and a half downward, thus forming a flap, the broad base of which was, after being dissected and freed, below the abnormal orifice. Then the catheter was seized, the urethra stretched and dissected, as it was done in the case just described, the scrotal flap folded and transformed into a tube, and then circularly united with the abnormal orifice. The further steps of the operation were the same as described above. Great care is to be taken to estimate properly where the base of the scrotal flap is to be established, so that the abnormal orifice, after being pulled forward, fits exactly to it, as it is not wise to put the base itself under much tension. The flap operation was much facilitated in this case by the presence of the extraordinarily smooth surface, which in fact resembled a mucous membrane alongside the raphe.

In the extreme case described above slight incurvation remained, which is gradually becoming less.

FIG. 5.—Result after operation.

In contradiction to the experience of such surgeons as have observed failures because they regarded some of the minor details of my suggestions as non-important, or objected for theoretical reasons without actually performing the operation, I may be permitted to say that in none of my balanic or penile cases has any incurvation been left.

As it is difficult to keep an ordinary penile dressing in situ I use a T-shaped piece of dermatoid gauze with a central opening for the catheter and provided with a number of lateral openings, which permit of passing the sutures through them (Fig. 2). The upper and lower sutures, after being knotted, are left long for the purpose of fastening the gauze strip. After the ends of the knotted sutures are pulled through the gauze strip placed alongside the posterior surface of the penis (Fig. 3) they are pulled out short. The two dissected ends of the strip are now carried around the penis and pulled through the

lateral openings and knotted, or held together by a safety pin (Fig. 4). This dressing is to be saturated with a mild solution of bichloride of mercury several times a day. It must not be removed before a week. Fig. 5 shows result after operation.

## SQUAMOUS CELLED CARCINOMATA OF THE OESOPHAGUS.

By W. TAYLOR CUMMINS, M. D.,  
Philadelphia.

(From the Pathological Laboratory of the University of Pennsylvania.)

With regard to the type of cell, carcinomata of the oesophagus are divided into two classes—the squamous celled and the columnar celled. The former is the much more frequently found, for, in fact, cases of the latter type are rarely encountered. For the most part the tumor is primary in this organ, but cases are reported in which it is the seat of metastatic deposits from the pharynx, thyroid, and cardia of the stomach. The oesophagus appears to be invaded but rarely by cancerous growth, for, out of a series of 722 cancers (1) in all parts of the body, only six were found in the oesophagus. It seems to enjoy a certain degree of immunity from neoplastic invasion in contrast with the organs lower in the alimentary tract. Zenker and von Ziemssen (2) have collected reports of 5,079 autopsies, of which 0.36 per cent. showed oesophageal cancer and 0.25 per cent. were primary.

The organ may be divided very conveniently into three segments, viz., an upper, or cervical, a middle, or thoracic, and a lower, or diaphragmatic, portion. Bland-Sutton (3) believes that the location of the neoplasm may determine whether it is of the squamous or columnar celled type, the former electing the upper two thirds and the latter the lower third of the tube. This statement must not be made dogmatically owing to the fact that statistics reveal many instances in which the squamous celled tumor primarily involved the lower third of the organ. As to the point of greatest frequency of involvement there seem to be widespread differences of opinion. It is conceded that the points of narrowing of the tube are the usual seats of the new growth. These are found at the levels of the cricoid cartilage, the bifurcation of the trachea, and the diaphragm. Possibly localized trauma at these apparently stenotic areas may incite tumor formation. Upon making a resumé of the statistics at hand there is revealed the fact that the new growths, including both types, are somewhat more frequently found in the lower third of the organ. Kraus (4) collected 901 cases, and of these 307 were found in the lower third, 302 in the middle, 158 in the upper third, and 45 involved more than one part of the organ.

The oesophageal tumor may be small and definitely circumscribed, or, on the other hand, it may be quite large with imperfect demarcation. In some instances multiple foci have been observed. There is usually some stenosis of the tube, but in a few reported cases this condition was absent. Ulceration and coagulation are likely to develop, and in many cases the lumen of the gullet is almost oblit-

erated. In those cases in which the carcinoma involves the diaphragmatic segment, Bland-Sutton has explained the forcible ejection of food after

five cases (5) of oesophageal carcinomata recorded at St. George's Hospital, London, these glands showed metastatic deposits in twenty-four cases.

FIG. 1.—Showing squamous celled carcinoma of the oesophagus at its border. To the left the penetration of the newly formed epithelium into the underlying tissue manifests itself in long, narrow columns. "Pearls" are absent.

swallowing by the fact that the tube assumes a spindle shape on account of the stenotic condition, and there occurs a hypertrophy of the muscular walls immediately above, thus favoring a forcible regurgitation of the oesophageal contents.

The squamous celled cancer is found much more frequently in men than in women. Bland-Sutton has observed it four times more frequently, while Makenzie, Zenker, and von Ziemssen have found it three times more frequently in men. The distribution in the sexes appears comparable to that of neoplasms of the stomach. Age seems to be a factor in its production. The prolific period is between forty and sixty years, while cases are recorded as early as the thirtieth year and as late as the eighty-fourth year. A few exceptional cases are on record in which the disease appeared in the nineteenth and twenty-first years. Curiously, the female sex seems to be attacked earlier in life than the male.

It has been said that carcinomata of the oesophagus do not often metastasize. This has been explained by the fact that the disease is often rapidly fatal, and metastases have not had the opportunity to develop. Certain it is that the patient, in many instances, is not long under observation subsequent to the development of localized symptoms, and death may take place from inanition, exhaustion, or septic pneumonia. Reports of metastatic growths are noted rather infrequently. The posterior mediastinal glands appear to be affected more frequently than any of the other structures, and their position renders easy access of tumor tissue from the thoracic segment of the gullet. Of fifty-

Evidences of metastases were observed in the liver in ten cases, in the lungs in six cases, in the kidneys in five cases, in the bones in four cases, and in the adrenals and spleen in two cases each. Widespread dissemination of the cancerous elements is distinctly rare. In a few cases reported in literature the tumor had existed for years without producing secondary foci, and they were generally of the flat celled type.

Among those who have reported upon cancer of the oesophagus with metastases are Burnet (6), Butlin (7), Wright (8), Scott (9), and Eskridge (10). Cancer statistics have been collected by Gillies (11) and Moak (12).

#### Personal Observations.—

My personal observations have been confined to a review of the autopsy records on file at the pathological laboratory of the University of Pennsylvania from 1874 to 1907. The number of records examined was 1,993, and of these ten showed squamous celled carcinomata of the oesophagus, distributed as follows: One in 1891, one in 1893, four in 1901, one in 1904, two in 1906, and one in 1907. In regard to the prevailing sex, the males outnumber the females, eight to two. This

FIG. 2.—Carcoma of epithelium of the "pearls" taken from another carcinoma of the oesophagus.

conforms with the assertions made by the other investigators that these neoplasms are much more frequent in men than in women. The ages ranged

from thirty-four to seventy-four years. The youngest cases, aged thirty-four and thirty-eight years, were females, while the youngest male was fifty. It appears that the disease may develop earlier in life in the female than in the male. In but six of the ten cases was the race noted, and all of them were white. Nothing conclusive appears in the literature with regard to the comparative frequency of the condition in the races. As to the points of predilection in the oesophagus, as already stated, there appear to be differences of opinion. In seven cases only was the site of the primary tumor indicated, and four of these involved the lower one third of the tube. Some of the statistics are based upon all cancers of the oesophagus, while personal observations were made upon the squamous celled type alone. The results are comparable for the fact that the indifferent type, the columnar celled, is so infrequently encountered. All of the tumors of this series appeared to be primary in the oesophagus, and involvement of not more than one segment had occurred. As to the general character of the tumors, four showed considerable ulceration, three were fungoid, and one was characterized by dense cicatrization of the oesophageal walls. In two cases the appearance of the tumor was not noted in the records.

The number of cases presenting metastases outnumber those without six to four. This surely does not show a comparative rarity of metastases in such tumors. For the most part the notes upon the gross anatomy of the organs were disregarded, and the diagnosis depended upon the histological findings. Metastatic growths occurred in the organs with the following frequency: Stomach, four times; liver, three times; pancreas, three times; lungs, twice; posterior mediastinal glands, twice; bronchial glands, twice; hepatic glands, twice; kidneys, once; pancreaticosplenic and lumbar glands, each once. The most widespread metastases occurred in Case II, in which foci were found in the liver, lungs, stomach, pancreas, hepatic, pancreaticosplenic, and bronchial glands. Histologically the primary and secondary growths were divided into two groups dependent upon the presence or absence of "epithelial pearls." In that the keratinous structure of the squamous epithelium of the oesophagus is poorly developed, the presumption might be that tumors involving such a tissue would usually show an absence of the "pearls." Such was not the case in this series, for five showed the presence of pearls and three showed absence of the same. In two cases this point was not noted in the records.

It seems plausible that the facts pertaining to the development of the tumors of the spinal and basal cellular types of carcinomata of the skin might readily apply to these tumors, i. e., the tumors in which the superficial strata of epithelium are directly concerned, show "epithelial pearls," while those in which the epithelium of the deeper or basal strata has proliferated, show no pearls. In the secondary as well as the primary growths the nests of tumor cells were much smaller in those cases showing epithelial pearls than in those in which they were absent. In several of the metastatic deposits in the latter group the squamous character of the cells was made out with some dif-

ficulty. Those cases which showed pearls in the oesophageal tumor showed the same in the secondary tumors. However, there appeared a tendency toward a diminution in size, and this was well shown in the tumor of the kidney (Case VII, Fig. 4), in which the "pearls" could with difficulty be recognized. It was thought by the author that a comparison of the frequency of metastasis in those primary tumors with and without "pearls" might reveal that there is less frequent metastasis in those with "epithelial pearls." Examination of the records reveals that of the four cases without metastases three showed pearls. So limited a number of cases makes it problematical but at least suggestive.

Several of the tumor sections presented rather unusual features. In one, a section of lung (Fig. 3) there was shown embolism of the smaller radicles of the pulmonary arteries by masses of squamous epithelium. The deposits were confined to these locations, and but few of them were seen. In a pancreas there was infiltration of a small lobule by squamous epithelium with the island of Langerhans vaguely evident. In a kidney the cortex showed a large, irregularly rounded mass composed of small nests of squamous epithelium, with very small deeply stained pearls.

*Metastasis.*—Under this heading a brief description of the lymphatic system of the oesophagus and neighboring structures is indispensable. The lymphatics of the oesophagus fall into two groups, viz., those in the submucosa and those in the muscular coats. The cervical portion of the organ drains into the superior deep cervical and recurrent nodes. The lymphatics draining the middle or thoracic segment pass to the posterior mediastinal glands, while those of the lower or diaphragmatic segment pass to the celiac plexus of lymph glands. For the most part the efferent channels of the posterior mediastinal glands pass directly to the thoracic duct, while a few pass to the bronchial glands, which in turn drain into the thoracic duct. Among the afferent channels of the celiac plexus, besides those from the oesophagus, are those from the hepatic, gastric, pancreaticosplenic, and lumbar nodes, while the efferents pass to the thoracic duct.

It is well known that carcinomata usually metastasize through the lymphatic system, yet there seem to be very good reasons for the belief that in some instances dissemination of the tumor tissue from the primary focus may be effected through the blood vascular system, and in some instances it seems possible to take place over mucous or serous surfaces. Let us discuss the several cases seriatim.

Case I showed the carcinoma involving the cervical oesophageal segment, but no metastatic growths were noted. Perforation of the trachea, however, had occurred. In Case II unfortunately the autopsy record failed to reveal the segment in which the primary tumor was found. There was widespread metastasis as before noted. Case III showed the tumor in the diaphragmatic portion of the tube, but no metastases had developed. Case IV showed the tumor in the lower portion of the tube as a very dense fibrous mass, but no metastases. Tuberculous laryngitis was a complicating

Case V showed the growth in the lower segment of the oesophagus with the development of metastases to the pancreas, liver, and lungs. Explanatory of the abdominal and thoracic metastases, it seems reasonable to suppose that dissemination

FIG. 3.—Showing lung with masses of squamous epithelium lying in two small branches of the pulmonary artery. The upper embolus shows apparent organization.

occurred through the blood vessels, for two reasons—an absence of involvement of the celiac plexus of nodes and the finding of emboli composed of masses of squamous epithelium in the blood vessels of the lungs (Fig. 3). The probability is that the oesophageal veins were effective in disposing of the cancerous material with the lungs as the primary seat of deposit. Destruction of pulmonary tissue by the tumor process would facilitate its transmission to the pancreas and liver by way of the arterial system. Case VI showed the tumor in the upper portion of the oesophagus, but no metastases were noted. Case VII showed the tumor in the thoracic segment of the organ, with metastatic deposits in the liver, kidneys, stomach, posterior mediastinal, bronchial, hepatic, and lumbar glands. Involvement of the mediastinal and bronchial glands was naturally direct. The primary tumor mass had extended to the root of the lungs. In the stomach it was only in the muscular coats. It seems most reasonable that in this case dissemination took place through the vascular system, with the root of the lungs as the probable points of entrance of the cancer tissue into the blood. The involvement of the hepatic and lumbar glands was probably secondary to the involvement of the organs drained by these glands. Case VIII showed the cancer in the diaphragmatic segment of the oesophagus, but there were metastases to the posterior mediastinal glands. It is evident that the tumor area was drained by the thoracic lymphatics. In Case IX the location of the cancer was not indicated upon the record. Metastatic deposits were

found in the stomach and are explainable possibly by continuity of structure. Case X showed the tumor in the thoracic portion of the oesophagus and secondary growths were found in the stomach, pancreas, and bronchial glands. The presence of the gastric tumor may be explained as before, while the tumor of the pancreas probably developed by continuity of structure directly from the stomach. Unquestionably the posterior mediastinal glands were affected to allow extension to the bronchial glands. The conditions herein brought forth appear sufficient to warrant the statement that the secondary tumors developed not only through the channels of the lymphatic system, but also through the blood vascular system. It seems possible that metastasis may also take place over mucous surfaces.

In the consideration of the present series of carcinomata relative to the frequency of the same, the results show that of 1,720 deaths, eight were associated with the oesophageal tumor or a frequency of 0.46 per cent. These embrace the autopsy records from 1897 to 1907. During this period all records were filed, and the percentage therefore is an accurate one. Another point revealed is the preponderance of the squamous celled tumor over

FIG. 4. Showing kidney with very small "epithelial nests" with two "pearls."

that of the columnar celled type. But one case of the latter type of tumor was found during the period. There is a presumption that the tumor of the oesophagus with "epithelial pearls" does not metastasize as frequently as does that without "pearls." Probably the same condition is true in this instance as applies to the reason why columnar celled cancers metastasize with greater facility than do squa-

mous celled cancers. A resemblance of the cells of the basal cellular type to those of the columnar celled type of tumor is assumed, so that the spinal cellular type (with "pearls") would appear to be of all malignant epithelial tumors the least likely to metastasize. Probably the shape of the cells and a difficulty in adapting themselves to the lumina of the smaller radicles of the lymph and blood vascular systems render dissemination more difficult. The development of secondary tumors appears not unusual in squamous celled cancers of the œsophagus.

## SOME OBSERVATIONS ON THE REMOVAL OF ADENOIDS.

By MILDRED J. BALLIN, M. D.,  
New York.

It may seem superfluous to again bring up a subject which has so often been the field of discussion. The writer's apology for doing so, however, lies mainly in the fact that one reads of so many various methods employed, and sees such a vast number of implements devised, that he does not consider it amiss to express his views as to which he regards the instrument most useful for this purpose, and the method which yields the best results.

The frequency of adenoid vegetations in children has of late years, since the publication of W. Meyer's paper on adenoids in the *Archives of Otolaryngology*, II, become a moment of importance to the pediatrician, as well as to the rhinologist, so that the physician is often confronted with the question whether it is advisable to have them removed. If one considers the vast improvement, both mentally and physically, observed in children following the removal of these growths it becomes evident that an operation of this nature is almost imperative in the great majority of cases. The frequency of adenoid vegetations in children is a well established fact, and it would not be placing the average too

high if we would say that eight out of ten children show, in one way or other, symptoms indicating the presence of these growths in the nasopharynx. As a rule it is found that when there is a hypertrophic condition of the adenoid tissue, the process does not limit itself to this area alone, but generally involves the faucal tonsils as well, so that we usually see a combination of both. It does not always say that where there is an adenoid growth there are tonsils present, but, on the other hand, if one sees a large pair of tonsils one can be quite certain that there are adenoid growths as well.

That adenoid growths are present at birth cannot be doubted, for one often meets with infants only several weeks old who display all the signs of the presence of these growths. As a rule, however, the fact that these vegetations are present does not become evident until the child has reached the second or third year, and then through a gradual enlargement, blocking up more or less completely the posterior nares, the child develops all the well known symptoms of this affection.

The symptoms which one usually observes in the children may be attributed mainly to the size and position of the growths. For, if they are small, they may pass unnoticed, and as is well known there are many persons who have adenoids which have never given them any trouble. Such small growths may, however, in the course of time, develop in size, owing to repeated local irritation, and then give rise to symptoms of nasal obstruction. This is often the case with adults, who never gave any signs until later life, and also with children who at first were apparently free.

The growth itself shows manifold forms, so that one finds it to be either a small, round protuberance, or a large, oblong growth, nearly filling up the entire posterior nares. The small growths are, as a rule, soft, small masses, having a granular appearance and situated at different parts of the pharynx. These need not give rise to any inconvenience, so that persons may pass through life without the knowledge of their presence. They are usually detected only when making a postrhinoscopic examination with the mirror. The large growths, on the other hand, are the ones which generally draw our attention, as their presence gives rise to the symptoms so well known. They are generally found to consist of one large, solid mass, situated in the medium line of the posterior nares, more or less occluding the postnasal space, and extending high up into the vault. On examination, such a mass is found to be made up of three lobes, a central one and two lateral, which are separated by rather deep clefts (Figs. 1, 2, and 3), or the lobes may be subdivided by numerous clefts, as shown in Fig. 3. These clefts are often the source of great annoyance, as they act as the receptacle for cheesy masses which frequently degenerate and give rise to the foul odor so often observed in children, as well as in adults. Then, again, they harbor bacteria, which keep up a suppurative process, so that there is more or less of a constant discharge of noxious material in the posterior nares. This discharge is expelled, giving rise to a constantly running nose, which is regarded by the parents as a permanent cold in the head. Then, again, the se-

cretion is being repeatedly swallowed by the children, as a result of which one often observes various gastrointestinal disturbances. Growths of this character are usually of a solid nature, and are attached to the posterior pharyngeal wall by a broad base; they contain masses of secretion as already stated, and are often spotted with very small superficial hemorrhagic areas. On microscopical examination they are found to contain bacteria, giant cells, and now and then tubercle bacilli. This tuberculous condition may, however, be merely local, or it may be a part of a general tuberculous infection.

The small growths may exist, as before stated, without giving rise to any symptoms, or may cause only a slight annoyance, which passes away in the course of time, and especially after the age of puberty. The large growths, on the other hand, are not amenable to treatment, do not pass on without notice, and generally get worse as time advances. These are the growths which give rise to the symptoms of nasal obstruction, with the various sequelae, which can be eradicated only by their timely operative removal.

The writer does not deem it necessary to go into

In performing the operation for the removal of tonsils and adenoids, one must always work with proper illumination. If possible it is always well to use an electric head mirror (as, for instance, the Clar light), having a rather powerful lamp. The current can be supplied with an ordinary dry celled battery, which is readily transported from place to place. If electricity is already installed, one can use the rheostat made by Wappler, which can be attached to any electrolyser, and thus regulate the amount of current to be used; where one has no current, one should use an ordinary head mirror, taking the light from a kerosene lamp. The illumination of the field of operation is very important, as one should never operate without a good light. Operating at a window with direct light is not good practice, as one can never see properly; the operator works more or less in the dark, and can never do justice to himself or to his patient. In the clinic, where we perform a large number of adenoid operations, we use the head mirror, taking the light from a strong fifty candle electric lamp. The great trouble with beginners is that they fail to keep the light constantly in the field of operation, thus working in the dark, and thereby failing in their attempt.

Of the numerous instruments devised, the writer has found the modified square Beckmann curette by far the best. It is the only instrument now employed by the writer for the removal of adenoids, as it has proved most satisfactory. There are three sizes, a small, medium, and large. The great variety of instruments, such as forceps, pharynx tonsillotomes, and the variously devised curettes, have not proved very satisfactory, and it has been the writer's experience that the successful removal of the growths depends not only upon a good technique of the operation, but also upon the proper selection of the instrument employed.

The forceps, although used by some, is not a very commendable instrument for this purpose, as one is never able to remove all the tissue, and one is bound to leave behind small pieces, which, in the course of time, give rise to a repetition of the old symptoms, necessitating a second operation. Then, again, when using the forceps, one is compelled to introduce it several times. This has its disadvantages, inasmuch as one is liable to bring about infection more readily, create unnecessary trauma to the vomer, soft palate, and pharyngeal orifices of the Eustachian tubes, and, lastly, one is compelled to work in a bloody field, thus obstructing the field of vision. The old fashioned triangular curettes of Gottstein, etc., are not very practical, as their shape does not conform with that of the growth, which is generally broad and oblong, and therefore do not answer the purpose as well as the square curettes mentioned above. The various pharyngeal tonsillotomes, or guillotines, so highly recommended by some, do not seem to be in great favor, although they sometimes do their work well. They are cumbersome, taking up too much room in the postnasal space, and do not always remove the entire mass. Even when one has used a guillotine, one is sometimes compelled to resort to a curette in order to remove the small particles left behind.

In selecting the curette, one should always choose the largest one for that particular case, for by doing so you cover almost the entire posterior wall,

the symptoms indicative of the presence of adenoids, as they are generally well understood. Yet he would like to state that in making the diagnosis it is, as a rule, not necessary to introduce the finger into the posterior nares. If a child is brought to the physician with the history of obstructed nasal respiration, his first duty is to examine the nose anteriorly to see whether the obstruction may be due to some foreign body, or to some physical defect in the septum, or in turbinates. If the parts present a normal appearance, while the posterior pharyngeal wall shows an uneven, granular condition, and is covered with secretion, and there are, in addition, the symptoms of nasal obstruction, it is perfectly needless to introduce the finger, as the diagnosis of adenoids is

whereby the whole growth comes within the grasp of the instrument, and one is thereby able to remove it entirely in one mass. If the proper sized curette is used the adenoid always comes away in one steady downward sweep, thereby avoiding the necessity of reintroducing the instrument. The great advantage in removing the growth in one mass lies, namely, in the fact that we can tell by its contour whether there is any portion of it still retained in the posterior nares. If, on removal, the growth is found to be lacking at any portion we can be almost certain that this corresponding part has been left behind, and thus necessitates a second introduction of the curette. Then, again, removal of the adenoid in one piece is proof that all the tissue has been taken away and that the pharynx is free. In cases in which the adenoid is removed piecemeal, as is the case with the forceps, one can never be certain that the vault is entirely free, and it is usually found that so called recurrences generally occur in cases operated in this manner. This mode of operating, which is rather prevalent, cannot by any means be regarded as ideal, and the results are not, as a rule, satisfactory, as all the tissue cannot be thoroughly eradicated. A recurrence of adenoids does not take place. It is a mistake to think that adenoids once removed grow again, as that is not the case. What does take place is this: When an adenoid operation has not been properly and thoroughly carried out, small pieces of the growth remain in the posterior nares. These, through repeated irritation, as catching cold, etc., swell up and become hypertrophied, thereby giving rise to the same symptoms as prior to the operation. Adenoids, when once removed, do not grow any more than tonsils when once removed. Another point to which the writer wishes to refer is that the curette should always be sharp. Some surgeons are of the opinion that the cutting edge should not cut, but rather tear through the growth, thus decreasing the tendency to hæmorrhage. The writer does not believe this to be the case, as he is of the opinion that one gets less hæmorrhage during the operation and less liability to secondary bleeding when the adenoid is cleanly cut through. It is frequently observed that when the curette does not cut well, and a small piece of the tissue is allowed to remain behind, there is more liability to secondary hæmorrhage than when the instrument is sharp.

It has also been the writer's experience that when a child is seen a day or two after the operation and complains of pain in the back of the neck, which is accompanied by more or less rigidity, he has invariably found that a piece of tissue has remained hanging in the postnasal space. This has become necrotic, thus being the primary source of infection and the cause of the entire trouble. When this is removed and some antiseptic lotion sprayed in the nose and throat for a day or so, the stiffness, foul breath, and pain disappear.

The manner in which the curette is held is also of importance. It has been the writer's practice to

hold the curette as shown in Fig. 4. For, if held in this way, we get the greatest amount of force neces-

FIG. 4.

sary, and, as experience has shown, quite some force is required to cut through a large sized dense adenoid, especially if operating on older children and adults. The action in using the curette lies mainly in the wrist, as it is not necessary to put the entire arm into play. Another way in which the curette may be held is shown in Fig. 5. This does not al-

FIG. 5.

low us to exercise as much control over the instrument as when held as stated before, but, nevertheless, answers the purpose well in some cases. The writer uses this method, however, when he does not wish to exercise too much force, as, for instance, when operating on very young children and infants.

The advisability of employing a general anæsthetic depends greatly upon the case at hand. As a rule, it is more advantageous to give a slight narcosis, especially in children of more advanced years, as one is able to operate more freely and more thoroughly. Older children are often very restless, and resist, so that the carrying out of the operation thoroughly without an anæsthetic is often utterly impossible, as they cannot be properly held. Small children, on the other hand, can be well held and offer little resistance, so that the removal of the adenoids is readily accomplished, and, as a rule, requires no narcosis. The giving of an anæsthetic is not free from dangers, so that the writer is inclined to do without it whenever possible. The danger lies not only in the administration of the anæsthetic itself, but mainly in the fear that particles of the removed tissue and blood may be inspired. In dispensary practice, where one is called upon to perform a large number of adenoid removals, it is impossible to resort to a general narcosis, as the time is too limited. In private practice, on the other hand, one has to give an anæsthetic, as the parents in the great majority of cases demand one. As to the choice of the anæsthetic to be used, the writer generally leaves that to the discretion of the anæsthetist, as it is usually found that one can do the most satisfactory work with that anæsthetic with which one is most accustomed. Personally, the writer prefers chloroform or ether, preferably the former. Nitrous oxide and ethyl chloride answer very well, and may be used instead of the former two, if desired. That the operation is accompanied by a certain amount of shock is certain; yet, in spite of the shock, the writer prefers to perform the operation without a general narcosis if possible, as the sequelæ of the shock are less to be feared than

When secondary hæmorrhage does occur, it is not adenoid tissue which the patient must swallow, as the packing is very disintegrative, and the patient may get up a considerable infection with all the pus and blood. It is a better plan in these cases to re-introduce the curette, then sweeping away any particles of tissue which have been retained by necrosis, and in this way bring about a cessation of the hæmorrhage.

the anæsthetic itself, and this is especially so in very young children, with a lymphatic diathesis.

The operation when performed without a general anæsthetic is carried out as follows:

The operation is carried out in the sitting position. The child is taken on the lap of a competent assistant, who holds its legs tightly between his, grasps the two hands with one hand, while he steadies the head firmly with the other hand against his chest. The patient must be well held, as a well trained assistant will greatly facilitate the work of the operator and the successful issue of the operation. Having the child thus in position the surgeon seats himself before the patient. A strong ray of light, as already referred to, is now thrown upon the field of operation, and a mouth gag is then introduced, which is held firmly in position by the nurse. The gag which the writer has found most serviceable is that of O'Dwyer, but when operating without the aid of a second assistant the selfretaining mouth gag of Whitehead has proved of greatest service.

The writer never uses a tongue depressor, as he deems it only cumbersome and entirely unnecessary, but finds that the index finger of the free hand is amply sufficient. A Beckmann curette, the largest for that particular pharynx, is now selected. This is grasped as shown in Fig. 4 and introduced sideways into the mouth (Feb. 6) until it has reached

FIG. 6

behind the soft palate. Here it is turned upright, so that it comes in contact with the posterior surface of the soft palate. Our next step is to pull the palate well forward, directing the curette upward at the same time, and keeping it directly in the median line of the postnasal space. This pulling the palate forward is a very important factor in the operation, as the success of removing the entire growth depends greatly upon this manoeuvre, especially in cases in which the growth is very large and almost fills up the entire posterior nares. Now, if, in such a case, you introduce the curette, direct it upward in the median line, and then make one firm downward stroke, but have neglected to carry out this important step, you only remove part of the adenoid, leaving the upper portion *in situ*. This is due to the fact that you do not get your curette over and above the growth, and thereby do not get the entire mass within the range of the cutting edge of the instrument. The upper part of the growth is thereby left behind, which is often the cause of trouble later on, and gives rise to the symptoms of a so called recurrence. In other words, the entire mass has not been removed. If, on the other hand, one follows the suggestion of first pulling the uvula well forward, one creates more room for the instrument, and then by directing it upward, always in the median line, one brings the cutting edge over and above the growth, so that the entire mass comes within

the reach of the curette. Having followed this precaution you now make one steady, downward sweep, thereby cutting the entire mass from its base. As the instrument descends you meet it with index finger of the free hand, whereupon the growth and instrument are both withdrawn from the mouth. If these steps are closely followed, the adenoid always comes away in one solid mass. (Figs. 1, 2, 3.) This is now examined in order to see whether it is complete, for if not, and part is missing, we can be certain that that missing part is still in place and must be removed. If, however, on examination the growth is found to be symmetrical and complete, we can be certain that there is no more adenoid tissue retained. In this instance, it is not necessary to introduce the finger into the postnasal space; if, on the other hand, we find that a part of the growth is lacking, we can introduce the finger to ascertain its exact location.

The hæmorrhage which generally follows the removal of an adenoid *en masse* is not very copious as a rule, and ceases within a few minutes. We then inspect the pharynx again to see that there are no small pieces hanging down. If a piece is pending, it should be removed. This is best accomplished by grasping it with forceps and cutting it off with a pair of curved scissors. It should never be taken hold of and torn off, as one can readily tear the mucous membrane on the postpharyngeal wall for several inches. This should be avoided, as it causes unnecessary after pain and trauma. Inspection, after operation, should always be carefully carried out, as one should never allow small pieces to remain hanging loose. They often give rise to unpleasant retching, nausea, and vomiting, and, besides, are usually the cause of secondary hæmorrhages. Then, again, they undergo putrefaction; this often gives rise to the foul odor which is encountered after an adenoid operation, and to the headache, general malaise, and rise of temperature. The otitis media which now and then follows the removal of adenoids may be attributed to this decomposition, inasmuch as the infection spreads along the Eustachian tubes into the middle ear.

As the writer has already mentioned, whenever one meets with rigidity and pain in the back of the neck after the operation, one is rather sure to find a piece of necrotic tissue pending in the postnasal space; this having become broken down, absorption takes place through the lymphatics, so that we have an enlargement of the glands in the neck with this accompaniment.

It can, therefore, be seen that it is of the greatest importance that the postnasal space be thoroughly cleaned out, and that no small pieces of the growth are allowed to remain *in situ*, for these are usually the disturbing factors which give rise to the various sequelæ detailed above. As soon as these pending infectious masses are removed, either with forceps or by introducing the curette again, and an antiseptic spray is used in the nose and throat, the source of infection is cleared up and the unpleasant after effects pass away in a day or so.

One more point to which the writer wishes finally to refer is, namely, the obstruction which one often encounters during the operation when making

the downward stroke. It often happens that the curette is impeded as it cuts through the growth owing to the marked prominence of the body of the atlas. This is particularly so in cases in which the posterior nares is rather narrow, owing to a slight bulging of the spinal column at that point. In such a case, even after the removal of the growth, the results are not always satisfactory, as the postnasal space is still too small to allow proper nasal respiration. If, therefore, one introduces the finger into the posterior nares and finds a very narrow space owing to this prominence of the atlas, one must be guarded as to the outcome of the operation, as the children often breathe no better after than before removal of the growths.

If, during the operation, one encounters this impediment, it is well to lessen the force used, slightly pulling the instrument forward and continuing the downward stroke, whereupon the cutting edge of the instrument glides readily over the obstructing area.

#### Conclusions.

To reiterate briefly we find:

(1) That the operation can be easily performed without any anæsthetic, taking from one to three minutes.

(2) That the growth comes away *en masse*, thus leaving no rests behind which are later the source of so called recurrences.

(3) That by examining the growth we can ascertain if a portion of it is still retained, and its location; and in addition we can show the mass to the parents, thus demonstrating the cause of the impaired nasal respiration and pointing out the necessity of operation.

(4) That complete removal leaves no rests behind, which later swell up and become hypertrophied, thereby bringing about symptoms similar to those prior to the operation, or so called recurrences.

(5) That by carefully examining the pharynx immediately after operation we remove pending pieces which would otherwise become infected, and lastly,

(6) That these pending pieces of tissue are generally the cause of postoperative hæmorrhages, and through their breaking down and becoming infected give rise to a secondary suppurating otitis media, with all its sequelæ, to the rigidity of the neck, enlargement of the glands in the neck, nausea, vomiting, general malaise, and a rise in the temperature.

The operation, as the writer has endeavored to detail, has been in vogue for some years abroad, and he acquired it while working in Hajek's Clinic in Vienna. Being convinced of its thoroughness he has used it exclusively in all cases of adenoid removal. It is a method which can be readily acquired by any one, with a little practice, and will always yield the best results.

If the removal of adenoids is performed as here given, it is almost certain that the results will prove most satisfactory and so called recurrences will be seldom heard of.

57 EAST FIFTY-EIGHTH STREET.

## PSYCHASTHENIA.

*Remarks on the Propriety of Considering It an Individual Disease.*

(First Article.)

By JOSEPH COLLINS, M. D.,  
New York,

Professor of Nervous and Mental Diseases at the New York Post-graduate Medical School; Attending Physician to the Montefiore Hospital; Neurologist to the Montefiore Home; Consulting Neurologist to the Hospital for Ruptured and Crippled, and the Manhattan State Hospital.

Within the past few years a new word, *psychasthenia*, has taken its place in medical literature. Dr. Janet, of Paris, suggested it as the name for a disorder characterized by mental, emotional, and physical symptoms made up principally of obsessions or imperative concepts, fears, doubts, anguish, uncontrollable movement, enfeebled will power, and some or all of the customary physical symptoms of neurasthenia. These symptoms and their associated occurrences have long been familiar to physicians. They have been interpreted usually as integral parts of such diseases as hysteria, hypochondria, neurasthenia, and some ill defined insanities of adolescence. Janet's proposition that they constitute an autonomous, constitutional disorder, such as epilepsy and hysteria, has been favorably received by physicians concerned with the study and interpretation of nervous and mental disorders. It might be gathered from reading medical literature, however, that psychasthenia and neurasthenia are one and the same disorder, as these terms are apparently used synonymously by some writers. This is an unfortunate occurrence, for, in reality, the two conditions are as unlike as hysteria and epilepsy. The fact that the occurrence of neurasthenia is apparently on the wane and that of psychasthenia on the increase has led more or less unconsciously to the conclusion on the part of some that they are the same disorder, to which it has become the fashion to give a new name.

The reason why neurasthenia is on the wane is not difficult to explain. In the first place, during the twenty-five years that followed its recognition as a well defined clinical disorder, the disturbances of function of various organs or sets of organs, such as the digestive tract, the genitourinary system, the circulatory system, etc., have been carefully studied, and in some instances the manifestations of their functional inadequacy have been raised to the dignity of a disease, which stands in direct relationship to the symptom complex to which the name neurasthenia is given. In other words, many of the cases which but a short time ago were labeled as neurasthenia are now diagnosed as disorders of the digestive system, of the vascular system, of the genitourinary system, of the mind, etc. For instance, in my clinic the diagnosis of neurasthenia was made and reported about 300 times in 1890, whereas in the year 1907 it was recorded only 82 times. During this time the diagnosis of dementia præcox, psychasthenia, arteriosclerosis, gastrointestinal neurosis, of metabolic disorder, conditioned originally by disturbance of the gastrointestinal functions, disseminated sclerosis, and general paresis, has been made proportionally oftener. Although the pendulum may be inclined to swing too far in the opposite direction—i. e., to the minimizing of neurasthenia—we must nevertheless admit that it is indicative of progress

in the realm of diagnosis to refuse admission to this category early or atypical varieties of the above this category early or atypical varieties of the above mentioned diseases.

Of these diseases psychasthenia is perhaps the most important, not so much because of its frequency, for in its fully developed form it is not of common occurrence, but because of the occurrence of "allied forms," to use a designation to which the modern psychiatrist is devoted, of which there are many. It would be very unfortunate if the belief that neurasthenia and psychasthenia are the same disorder should become accepted. Psychasthenia is quite different from neurasthenia, although it may be an important factor in contributing to neurasthenia. Psychasthenia is a constitutional psychoneurosis that has its origin in a neuropathic constitution, which is inherited, not acquired.

A better idea of psychasthenia, as it displays itself, may be gathered from a typical case than from any description, which must necessarily be a composite picture. The most complete and typical case that I have ever seen is the following:

A single lady, then thirty-two years of age, consulted me in 1901. Her family history, or as much as she knew of it, was interesting and important. She was the daughter of Irish immigrants of more than average intelligence. The father's distinguishing characteristics were industry and penury. He had held a position of some trust for many years and he saved a considerable amount of money. Saving money was his passion. Aside from going to work six times a week and going to church once a week he had never been known to have any other interest. If he had ever had much family feeling there had been no display of it after matrimony had ceased to be a novelty. He had every distinguishing feature of the miser, and this makes the enumeration of them here superfluous. He had some virtues, but they paled in comparison with his limitations, and were forgotten and entirely obscured in the atmosphere of his ruling passion. The mother was an intelligent, kindly, sympathetic, moderately emotional, gentle woman, who succumbed to diabetes when sixty-six years old. The parents had had seven children, four of whom died in infancy. My patient was the eldest of those that lived. The second, a sister, a most competent, intelligent, well balanced young woman is a successful wage earner. The third, a young man, is what may be called a dilettante, using that word in Goethe's sense to describe a man who is always venturing on tasks for which he is not adequately equipped. He studied law and was admitted to the bar, but was unable to hold a position in a law office. He undertook mercantile life and was unsatisfactory to his employers. He espoused a political career, but the organization with which he associated himself soon dropped him. He then became a follower of Henry George and a student of philosophy, but he abandoned both interests after a year or more devotion to them. He was convinced that he had histrionic talents, but on account of being thoroughly unappreciated, misunderstood, and out of harmony with his environment and his people, he finally made his displeasure and inadequate appreciation manifest by taking to a wandering life, and since a considerable time nothing has been heard of him.

My patient had, when she was twenty-four years old, symptoms somewhat similar to those for which she consulted me, but they lasted only a short time. They will be mentioned later. In order to give a faithful presentation of her history I shall state it in her own words, the sequence of occurrence of the symptoms being practically as related. "About a year ago I seemed to go to pieces. Whenever I attempted to do anything, such as housework, shopping, theatres, and the like, I would get used up very quickly, and the resulting fatigue was so great that I could scarcely sit up. My hands and arms, especially the left, would get numb and powerless after doing any work such as doing my hair, sweeping, writing, etc. In other words, my grip would weaken so much that I had to use my hand without my fingers. Most of my life has been an adventuresome, partly in

the back of the neck, specks before eyes, and rings on looking into a bright light. Objects would take on a far away appearance and everything would lose its proportion. At times a queer sensation would come on as if I were in a new sphere. Another evidence of this weakness was that frequently I let things drop that I was holding. Then I have a great deal of trembling of my hands and occasionally also of my legs, and I have had twitching of the eyelids and of the lips and of different parts of the body, particularly after excitement or after exertion such as walking and hurrying. I have a prickling, tingling, stinging sensation in the head which is sometimes accompanied by throbbing. At times, after or without exertion, I break into a perspiration."

In addition to the symptoms of this kind, all of which had somatic reference, she had peculiar emotional symptoms. She had days in which she felt restless, discontented, anxious, without attributable cause. She felt as if she would like to destroy things, a peculiar feeling which she was unable to put into words. When she was asked to attempt to do it she said, "It's a feeling as if I wanted to fly, which I have all through me." She was not emotional in the ordinary sense of the term, and she has the appearance of being rather a phlegmatic person with more than the average amount of mental and emotional equanimity. Nor at this time were mental and emotional symptoms at all conspicuous compared with the purely somatic symptoms.

In response to the ordinary treatment for the neurasthenic state, particularly tonic baths, massage, high frequency electrical currents, superalimentation, etc., she recovered and remained well until the summer of 1903, when some of the symptoms returned, and with them a number of others which had not existed before, or, if they had, only in a very rudimentary form. She described these as follows: "I was at a summer watering place stopping at a hotel, and one day, just before luncheon, it suddenly popped into my mind that I could not go into the dining room. Just why I do not know, but I finally succeeded in persuading myself to go in, but soon I became so excited and worked up that I had to jump up and almost rush into the open air. It was not that I felt the need of air. It was a mixture of fright, excitement, dread, and anticipation, which disappeared, or at least, abated as soon as I got out."

The only somatic symptom that she had at this time was pain in the back of the head. After a while the dominant idea, viz., that she could not go in the dining room disappeared, but later other and far more distressing ones took possession of her mind, particularly ideas of homicide. Suddenly the thought would flash into her mind: How easy it would be to kill this or that person. For instance she was sitting one evening reading, her sister on the other side of the table, when, without antecedent thought or motive she looked up at her sister, and like a flash the thought came to her how easily she could kill her now by just thrusting the sharp end of the scissors into her neck. Again, at night after she had gone to bed, she was seized with the same thought. It frightened her and made her distrust herself, and filled her with a violent feeling towards herself, and although she knew she would not do it, nevertheless, she felt compelled to get up and go into the next room that she might not be on the spot providing an all powerful impulse to slay came to her. Moreover, it distressed her terribly that she should be compelled to give tenancy to such thoughts. They were so terrifying that they made her afraid of herself and they were so loathsome that she despised herself for having them.

A few days ago she received a letter from a friend who had spent some time with her, and who suggested that, being on the way to New York, she would visit her. The first conscious thought on reading the letter was, "How easy it would be to kill her when she comes here," and for a long time this thought would bound into her consciousness without apparent relevancy. Another came while she was sitting in the park one day. Two boys of ten or twelve years passed her, and like a flash the thought came into her mind, "It would be so easy to kill those boys." The thought was not associated with such concomitant as to whether or not she might be found out in her guilt and punished. She was sure that the sentiment associated feeling was one of shame and humiliation. She did admit, however, that in discussing the matter with herself she thought that possibly she and her sister would

be quite as well off if they were dead. Other uncontrollable thoughts that she had were of jumping into the subway, jumping from the elevated railway, jumping into river, cutting her throat while taking a bath, killing some member of her family, and suggestions of the "most immoral acts" one could commit. She might be walking in the street or in a shop and passing a man, instantly a thought of the "most awful" nature would pop into her mind, and on occasions it would be associated with the impulse to say bad words, but the latter she had been able to keep from saying aloud, but they came articulately into her mind. It distressed her terribly that often these thoughts were associated with the most disgusting looking men, tramps, Italian laborers, etc. Another was an impulse when in church to cry out and revile things always considered sacred, or to get up in church and swear and blaspheme at some special movement, such as as the elevation of the Host.

So far as could be seen she seemed to be in excellent physical health; she had no indications of insanity, and she was concerned quite like a normal person would be about the dominant thoughts that took possession of her, and fastening upon her mind crushed out every capacity for thought save the disgusting and debasing suggestions which they caused.

She did not have them continually, but she could not tell when they were going to come nor how long they were going to stay. When she was tired they were more insistent and dominant. For weeks they would be very aggravating and then a respite from them would follow. At other times such impulses were momentary. They would shoot across her mind like lightning across the sky and leave no trace. She was not so terror stricken of them as she was formerly because she had seen that she did not conform her conduct to them and no one save her sister whom she told knew of them. After about three years she began to have other symptoms, particularly a sensation when sitting as if she were falling off the chair to the left. This was particularly so when she was sitting at a table, in church, or on a bench in the park. When she sat in the middle of the seat she felt as if she were going to fall over because she had no support. This reminded her of the symptoms she had had a number of years (ten) ago. Symptoms similar to this and a sensation of strangeness, of unreality, used to come over her. It seemed to her then as though she must have lost consciousness for there would be a gap in time for which she could not account. At other times she would not get all the dictation that she was taking, but no one noticed that there was anything peculiar about her. That is, she did not faint nor seem to become confused. She felt as if some one other than herself was taking the dictation instead. After a long vacation these symptoms disappeared.

Now she has them again and with them sensations of being in a different world where things have a semblance of familiarity only. This sensation seems to last a long time, but in reality it is very brief. She gets tired sometimes after walking two blocks, and so prostrated that she feels irritable and tearful. At another time she could walk a mile without any trouble. She had had one spell of high temper following a sudden fatigue. She is quite positive that she is more able to bear the distressing thoughts and dominant ideas and that she has them less dominantly if she eats often and a great deal. If she

like a mad or takes a small quantity of food she is sure to feel worse. The consequence of this was that she had developed a ravenous appetite. She had often noticed that after menstruation she was weak and she was apt to have more of these obsessive ideas then. Examination of the uterine organs showed them to be normal in size and position. She complained of pain in lower part of abdomen when she rested on her abdomen, or when she bent over without corsets. She was much larger around the abdomen and hips than she had been. She sometimes had to pass urine four to five times an hour, and even then the sensation of desire to urinate was not relieved. She had noted latterly that statues, and pictures, as well as man suggested sexual intercourse, especially if she was tired or menstruating. Obsessions of homicide were also very dominant at such times.

Latter new symptoms, such as twitching of the head, arms, and legs developed. Perhaps "twitching" does not describe the movement she says, it is not a sudden movement of

one part of the body or another. Twitching of her entire body was often the last thing remembered before falling asleep. Flushing of the face with throbbing of the heart and throbbing in the abdomen, especially when resting, were of frequent occurrence. After meals she felt similar throbbing and also after exercise. Fear of falling when going downstairs and when standing and not having something to lean against was also most distressing. She felt as though she would fall from chair when sitting at meals. She must have a footstool to brace and steady herself and must lean on table for support. Objectively there was no evidence of the slightest insecurity. At the conclusion of a meal she felt much stronger.

Recently she had the sensation of falling from a chair and thought that she had lost consciousness or fallen asleep, for her surroundings seem unfamiliar. She could not describe them, but like a place which she had seen and forgotten. After walking a few blocks she felt like falling and had pain in back and head.

After this she had a long period of respite from the worst symptoms. Then she sprained her ankle. After she recovered she began to have weak feelings, a sensation of falling over to left. If this was very pronounced she had at the same time numbness in the left arm lasting a few minutes. All this summer she had marked flushing of face, more or less constant, and when this was very marked she felt very excited. Often this came in a sort of an attack.

The patient's intelligence doesn't call for particular comment. She discusses her infirmities with nearly as much impersonality as if they were those of another. She is terribly chagrined and distressed at the character of many of her symptoms, which, however, she discussed with no one save with her physician, and she made the most commendable efforts to get rid of them. She has no dementia in the customary sense of the word, though there is unquestionably enfeeblement of some of the mental processes. Her capacity for verbal association and her reaction time are about those of a woman of average intellect. She, however, has great difficulty in accomplishing things that require long or close mental effort. And she has lost her skill as a stenographer.

When we review her symptoms we see that they practically fall under three heads: Obsessions, peculiar movements, which she calls uncontrollable, twitchings of different parts of her body, agonizing emotions and manifestations of psychological insufficiency, sentiments of unreality, of somatic strangeness, and of depersonation, and finally diminution of will power. The obsessions are involuntary, automatic, and irresistible. They come into her mind without the slightest warning and take possession of it. The only relation between their occurrence and any outside factor is what has been noted in regard to fatigue. The patient makes her best effort to prevent them or to circumvent their dominant operation, but she accomplishes little in this direction. She realizes how strange and morbid the obsession is and how contrary to her nature and thought the obsessive ideas are, and she is able to discuss them in an impersonal way, but this has no effect upon the tenaciousness of the obsession, nor can she shut it out by effort of will.

The various uncontrollable twitching movements, which are to be interpreted as manifestations of psychological operation upon the motor areas of the brain despite the action of the will, seem also to occur much more severely and extensively when she is fatigued or when anything has occurred to lower physical or mental vitality.

Manifestations of psychological insufficiency, which were the first to develop in this young woman's case, disappeared for a number of years before the disorder itself seemed to have fastened upon

her. Later they became the most distressing phenomena of the disease. It is to be noted that in this case the patient was not of a hesitating, irresolute, selfdistrusting person, as many psychasthenics are, nor was there any very conspicuous inclination to selfdepreciation, which is common in so many of them. Her lack of selfconfidence was displayed only in the attitude which she took toward her obsessions. She had done her best to overcome them and had failed, therefore she could not rely upon herself to cope with them. She did not have many of the fears which psychasthenics often have, nor was she a victim of exaggerated morbid scrupulosity.

The feeling of unreality, of disembodiment of personality, of swaying and falling, are fairly constant phenomena of fully developed psychasthenia. And they may be looked upon as a profound exaggeration of sensations which many so called normal individuals have. The sensation that they have of being in some new atmosphere, in some strange place, and at the same time of having been there before, is a favorite topic of the poet,

"I am aware of other times and lands,

Of birth far back, of lives in many stars,"

and it is also that which the modern literary mystic, such as Lafcadio Hearn, is constantly thrusting before us. Only in those instances such sensations are presumably pleasurable, but in the psychasthenic they are distressing.

The sensation of insecurity, of swaying, and falling, is a curious one, and it is possible that it may be interpreted as the cessation of the reciprocal relationship existing between the will power and the centres or areas of equilibration.

The effect which physical and mental effort had upon her symptoms has often been noted, and peculiar fatigue is one of the stigmata of the disease.

Janet has distinguished six clinical varieties of psychasthenia: 1. The doubter, those in whom obsessive ideas are not very precise, more of the nature of a general mental inclination rather than a specific idea, such as a craze for research, for explanation, for computing, etc. 2. The scrupulous, those whose obsessions are of a moral nature. Their manias are of literalness, of statement of exact truth, of conjuration, of reparation, of symbols, etc. 3. The criminal, those whose obsessive ideas are of homicide, theft, and other overt acts. It is generally conceded that in this variety the impulsive tendency is stronger than in any of the others, but nevertheless the individual rarely responds to the obsession, especially to what may be called the major one, such as homicide. 4. The inebriates, dipsomaniacs, morphinomaniacs, etc., in whom the impulse seems to be least resistible. 5. The genetically perverted. 6. Delirious psychasthenia, a condition in which a delirious state of the mind concerned with the obsessions occurs.

Whether such classification contributes to a better understanding of the conception of the disease and its modes of display, it is quite impossible to say. But that there are cases that fall rather narrowly into each of these categories must be admitted. And that there is ample justification for describing a psychonurosis of deviates, or on a degenerative basis there can be little doubt.

## THE MANAGEMENT OF FEBRILE CONDITIONS AFTER ABORTION AND LABOR.\*

By ABRAHAM BROTHERS, B. S., M. D.,

New York,

Adjunct Professor of Gynecology at the Postgraduate Medical School; Visiting Gynecologist to Beth Israel and Yorkville Hospitals.

If one will take the trouble to look over the files of the medical journals issued during the past five or ten years, he will find the literature of the puerperal fevers so extensive and ponderous that he will be apt to quit the attempt in a heavy and confused frame of mind. No sooner will he have formed an opinion in one direction than the investigations of a new set of observers will tend to dispel his convictions in another. Take, for instance, the bacteriology of the puerperal uterus. One set of competent observers, investigating more than 500 cases, tell us that the uterine discharges are ordinarily sterile in anywhere from 64 to 100 per cent. of the cases after childbirth. On the other hand, another set of equally competent observers assure us that, in some 250 cases examined, the sterility of the uterine lochia ranged between 0 to 36 per cent. of the cases. Perhaps Little—to whom we are indebted for an excellent résumé of the subject—may be right when he attributes the different results to the circumstance that the observations were made on different days of the puerperium, when the percentages of sterility varied accordingly. Similarly, in this period of time, have we witnessed the rise and explosion of different highly lauded methods of treatment, including the injection of chemicals in the blood and operative procedures of various kinds. So that we are tempted to put our reading material to one side and wearily ask ourselves how much further have we advanced in the management of the puerperal fevers, and how much of real importance have we learned in the past ten or twenty years.

I assume that the ætiology, pathology, and bacteriology of the puerperal fevers—as taught these many years since the time of Holmes, Semmelweis, Pasteur, and Lister—are today thoroughly understood by every educated physician. When we are told, for instance, that fifty years ago the mortality from childbed fever in the Boston Lying in Hospital averaged from 20 to 30 per cent., and grew to such proportions that the service had to be discontinued for several years, and that today only one woman in 1,100 dies from the same disease, we have indeed cause for congratulation. It is agreed that sources of infection occasionally arise from sources independent of the accoucheur. Thus vulvovaginal abscesses, chancres, rectovaginal fistula, pus tubes, or gonococci transmitted during sexual intercourse may each be responsible for puerperal fever in isolated instances. Still, it is a safe assumption that, in by far the largest proportion of cases, infection comes from without. Although puerperal mortality has been almost reduced to *nil* in institutional statistics it is nevertheless a fact that in private practice the mortality remains about the same as it was twenty years ago. So long as this is the case there must be no let up in holding the midwife or physician

\*Read at a meeting of the Section in Obstetrics of the Academy of Medicine, held on December 26, 1907.

morally responsible until results prove that patients in their homes are surrounded with the same safeguards of asepsis and antisepsis as their sisters in obstetric institutions.

Further, assuming that the medical attendant is sufficiently able to recognize febrile conditions due to complicating or coincident conditions—such as influenza, pneumonia, bronchitis, tonsillitis, typhoid fever, appendicitis, cholelithiasis, pyelitis, etc.—we proceed to the consideration of the febrile conditions directly due to abortion and labor.

A slight digression of a personal nature may be pardoned at this point. Some twenty odd years ago I had the privilege of a double maternity service at Bellevue Hospital, under the late Dr. Wm. T. Lusk. In those days our methods of preparation of patient, doctor, and nurse were nearly what they are to-day. To be sure, we used vaginal douches more freely, we used chemical solutions instead of boiling for our instruments, and we used no rubber gloves for the hands, which were otherwise carefully scrubbed and treated antiseptically. In every respect scrupulous cleanliness was observed, and our patients—some of them delivered to us directly from the city's gutters—mostly escaped septic infections. Indeed, our results were so good that the late Dr. Lusk used to publicly announce that he would rather deliver a woman in our maternity ward than in the most elegant surroundings of the rich. My first years of practice were spent among the dirtiest and poorest inhabitants of the city. In spite of this I was able, in 1,500 tenement house deliveries, to record but one death from septicæmia in a selfdelivered woman who, without my knowledge, had borrowed an old syringe from a relative and used it for vaginal injections. Of course, I saw numerous fatal cases in this time, but they were either midwife cases or cases delivered by colleagues. Since then my hospital connections and consultation work have provided me with liberal opportunities for observing and studying the puerperal fevers, which are still of common occurrence in the practice of midwives and those general practitioners who have not yet properly mastered the secret of surgical asepsis.

Without attempting to dilate on the details of prophylaxis and prevention let us now proceed to a consideration of the management of the puerperal fevers.

Dr. W. M. Polk, in the course of a clinical lecture, once remarked that the condition of a woman after an abortion could be compared to an apple plucked unripe from the branch. At full term the delivery of the child and easy separation of the placenta could be similarly compared to the dropping of the apple to the ground after it had fully ripened. There is, further, a difference to my mind between abortions of spontaneous nature and those induced artificially; in the latter variety is sepsis from without more apt to be introduced into the uterine interior.

After spontaneous abortions the retention of placental tissue, etc., only infrequently gives rise to fever and seems rather to subject the women to irregular uterine bleeding. I have known cases in which retained products of conception were carried for days, weeks, or months in one case seven months without producing any febrile disturbance.

On the other hand, the cases of sapræmia, or even some of the worst varieties of septicæmia, are met with in women in whom there has been tampering with the uterine interior of an artificial or criminal nature.

Abortion, especially the criminal varieties, may give rise to fevers due to sapræmic toxæmia, bacteriæmia, parametric exudates, purulent collections in the Fallopian tubes or peritoneal cavity (usually in Douglas's cul de sac), occasionally to necrotic or suppurating fibroids, and to varying grades of peritonitis. Often several of these conditions are combined in the same case.

The treatment of retained tissues after abortion differs somewhat from that employed after labor at term. Although the principle of cleaning out the uterine interior is the same in both, I have always felt that one could be much more thorough in the operative manipulations of the uterus after abortion than after full term. After labor the woman is usually in a much more exhausted state and must be handled with the greatest gentleness, for every additional traumatism is associated with the risks of fresh infection in an already overtaxed and debilitated system. I respect the statement of Gilliam when he says that "to the puerperal woman the man with a curette is more to be feared than shot and shell on the most sanguinary field of battle." I shall go a step further, and state that only the clearest indications should induce the physician to transfer such a woman from her bed to a table for the purpose of forcibly dragging down the cervix in tenacula forceps and introducing the Chamberlain tube or double current intrauterine metal catheter. Only too often is the subsequent violent chill and high rise of temperature attributable to these manoeuvres.

But after abortion conditions seem to me to be somewhat different, and for twenty years I have not hesitated to use the curette—a semisharp, large curette—in cases of retained placenta. In such cases I prefer to begin with placental forceps, then I remove adherent placenta with one or two different curettes, and wind up with intrauterine irrigation of normal salt solution. If drainage is used at all only a narrow strip of gauze is left in the uterine interior. Of course, if the fever, in abortion cases, follows the perforation of a uterus the curette, if used at all, must be handled with the greatest care. In the presence of pus tubes, pelvic abscesses, general peritonitis, or bacteriæmia the curette is simply harmful.

When called to a patient suffering from fever after delivery at term I begin with the examination of the breasts. An early rise of fever is often due to this cause, and I have known inflammations of these organs, even to the extent of abscess formation, to be overlooked in the attempt to locate a pelvic origin for the rise of temperature. The term "milk fever" may be banished a hundred times from our books, but to my mind it would be far better to retain this objectionable designation than to have women unnecessarily and indiscriminately subjected to the traumatism of an intrauterine douche or a "scraping" with the omnipresent curette. It is a difficult matter to prevent the swing of a pendulum from going to extremes in either direction in the teachings of our profession.

The puerperal fevers proper are today divided into two main groups: I, the toxæmias, and, II, the bacteriæmias.

In *toxæmia* there is regularly present in the uterine cavity some portion of the products of conception, usually placenta, disintegrating clots of blood, or débris. Microorganisms feed on these masses, and give off toxins which are absorbed in the blood and cause febrile disturbance. Sapræmia in these cases is the synonym of the toxæmia due to the putrefactive products of the saprophytic bacteria which are present in all kinds of decaying material. A second variety of toxæmia in these cases may result from the absorption of the products of distinct pathogenic bacteria.

In *bacteriæmia* the bacteria themselves circulate in the blood and usually include (1) phlegmasia alba dolens; (2) septicæmia, pyæmia, septicopyæmia (sometimes gonococcus absorption); (3) the peritonitic types of sepsis. The last varieties, in a subacute form, seem to owe their origin sometimes to a toxæmic state, and occasionally include some of the gonococcus types of puerperal infection (Wm. S. Stone).

For practical purposes I beg to submit the clinical classification into four groups which has guided me these twenty years in the management of the puerperal fevers.

Group I. *Fever due to retention of infected placental débris or blood clots.* Between the third and sixth days post partum these patients usually manifest their first symptoms with chills and a rise of temperature. There may be little or no pain, but the fluor has a decided odor if the canal of the uterus is not prevented from discharging it by a flexion of the corpus uteri on itself. I pass by, as familiar to you all, the associated headache, malaise, restlessness, backache, or occasional delirium. The uterus is large, and the exploring finger introduced gently into the uterine interior recognizes placenta or blood clot. If the discharges from a little placental débris are simply pent up because of a flexed uterus, a simple irrigation after straightening the uterine canal may be sufficient. Ordinarily it will be sufficient to sweep out with the finger or placental forceps the retained clots or mass of placenta, or even the large, blunt curette may be called for in some cases, when an intrauterine irrigation with normal saline solution will complete the operation. I have regularly administered ergot to keep up uterine contraction. The use of alcohol, as recommended by Carosso and Ill in this class of cases, I have no experience with. If the fever does not drop in a reasonable period of time after this method of procedure it is usually because one of two conditions is present—local pelvic inflammation or bacteriæmia.

Group II. *Fever due to pelvic inflammation.* These cases may be associated with or follow the first group. If present with retained placental débris, unless the emptying of the uterine contents is done with the greatest gentleness, the inflammatory processes will naturally be aggravated. Hence the presence of pelvic inflammation is ordinarily a contraindication to intrauterine irrigation or curettage unless in the most exceptional instances and then only in the hands of experts. The pelvic inflamma-

tions may be in the form of salpingitis, oophoritis, pelveoperitonitis, or parametritis. Whether these inflammations arise from backward continuity of inflammatory processes or from lymphatic or blood absorption does not enter into the province of a practical paper like this. Suffice it to say that they may all end in spontaneous absorption, but occasionally suppuration supervenes. Long continued cases of fever after childbirth belong usually to this group. I have not been able to convince myself that the usually low grade fever with correspondingly slow pulse rate follows any particular type. Chills are infrequent or mild, and the facial expression flushed and hopeful. The addition of localized pain somewhere about the uterus and the finding of an exudate or mass to the front, to the back, or to either side of the uterus usually makes the diagnosis very easy. As a rule, these patients recover under local abdominal refrigeration, prolonged rest in bed, and hot vaginal douches given at short intervals. In fact, I believe that most cases would get well if kept simply in bed. The use of the silver ointments or blisters in the region above Poupart's ligament and the pubes can certainly do no harm. It is well to examine the blood in protracted cases, for I have found pus in a number of cases in which the fever had apparently dropped to the normal, but the exudate would not disappear. In such cases the presence of an increased leucocytosis ranging between 10 and 20 thousand and a polynuclear count exceeding 75 to 80 per cent. would induce me to advise operative intervention with the prospect of finding a pus focus. Of course the clinical manifestation of repeated rigors and marked fluctuations of temperature, with profuse sweating associated with a pelvic mass, would lead us to the same diagnosis and treatment. Where it is possible to wait for "pointing," this is the best course to pursue, for then an incision into the fluctuating tumor in the vaginal roof or over Poupart's ligament ordinarily allows of the easy escape of pus and the cure of the patient. In one case, however, I found the abscess dissecting its way upward beneath the peritoneum covering the psoas muscle. This case necessitated the performance of a laparotomy before the pus pocket could be reached. In a certain number of cases abdominal section, which ordinarily in these patients is not called for before six or eight weeks have elapsed, will reveal only thickened and infiltrated tubes. While most of these patients regularly get well after such operations, I am satisfied that many of them would have equally got well under prolonged rest in bed and under the use of ice applied locally. I cannot insist too much on leaving patients with pelvic exudates alone. Jackson's epigrams teaching us how to kill a puerperal woman suffering from sepsis apply with particular force to this class of cases: "1. Use all the salts you can persuade her to swallow; 2. Poison her with strychnine; 3. Use the curette and intrauterine douche indiscriminately; 4. If she is still alive perform an abdominal section."

Group III. *Fever due to bacteriæmia (Septicæmia).* Sometimes bacteriæmia occurs before delivery, and in my experience with a few cases is a most ominous condition. Ordinarily, however, a few days elapse after the labor before the

onset of the symptoms. While I have seen a few fatal cases, which began with a pulse range of 100, the rule is that from the start the pulse counts 120 or more. Still, in nervous women, the value of the pulse count only holds good when taken during sleep. Chills occur once or several times daily, and the temperature chart shows marked fluctuations. The facies usually are anxious and drawn. Intense restlessness, often going on to delirium, characterize many of these cases, although some of the worst cases I ever saw were perfectly clear minded up to a short time preceding exitus. As distinguished from sapremia due to retained placenta, the lochia are diminished or absent and free from odor. There is usually a complete absence of abdominal pain. In spite of an absence of local symptoms these cases may present, on autopsy, gangrene of the uterine mucosa, abscesses in the uterine wall, pelvic lymphangitis, or thrombophlebitis of the pelvic veins; also lesions may be found in the more distant organs, such as abscesses, ulcerative endocarditis, etc.

The few cases in my experience which developed before the onset of labor died, and it has seemed to me that the treatment of the future will take into consideration the earliest possible removal of the uterus in the hope that the system may still have sufficient power to fight off successfully the beginning systemic bacterial invasion. After, however, the blood examination shows the presence of streptococci or staphylococci the patient's chances after a hysterectomy seem, to my mind, exceedingly slim. And even though a patient here and there may recover after operation, we know that occasionally such patients recover without operation and in spite of the presence of streptococci in the blood. At all events, the two patients subjected to hysterectomy by me died, as well as one with unilateral thrombosis of the pelvic veins on whom I resorted to ligation of the ovarian and internal iliac veins.

What the opsonic treatment with bacterial vaccines holds forth for these cases is still a matter for the future to determine. The results of Wright are not very encouraging; and, although two out of his three mild cases got well, Jewett does not seem to be very favorably impressed with the treatment. Similarly the use of antistreptococcus serum, which I employed many years ago and again recently, have failed to excite any enthusiasm in my breast. I make this statement advisedly, with the full knowledge that S. Marx, Hamilton, and others have recorded very favorable results. The only desperate case which actually recovered ten years ago, and whom I saw many years later alive, did so after exhibiting dreadful pyæmic manifestations requiring wholesale surgery, and this woman was left ultimately with an ankylosed knee joint. It was never clear to my mind that she did not recover rather in spite of than because of the heroic treatment instituted. Another instance which left the same impression on my mind occurred two years ago in my service at Beth Israel Hospital. The diagnosis of pelvic lymphangitis was made after consultation, in a septic case, by Dr. Boldt and myself. After curettage I opened up the posterior cul de sac and drained the lower pelvis with gauze. She ran a characteristic fever range just the same, and then

we diluted her blood with saline solution. We used later antistreptococcus serum without apparent benefit. She finally was attacked with a septic pleurisy with effusion, for the relief of which we drew off several pints of sanguineous fluid—and the patient got well! I may be pardoned if I am often tempted to leave some of these patients to fight their own battles for life in the hope that the struggle between the phagocytes and the bacteria will terminate in favor of the former. Of course everything in the way of alcoholic stimulants, cardiac supporters, nourishment, and careful intelligent nursing should be prescribed to maintain and conserve the patient's resisting powers.

The gonococcus type of puerperal infection I have recognized about a half dozen times. Although the bacteriæmic element is present, these cases usually run a mild course and terminate in recovery; still there are three cases on record by Mann and two cases by Davis which ended in death. Those cases which I recall developed symptoms of the pelveoperitonitic type about the second week, and the patients got well under prolonged rest in bed. Of course, gonorrhœal pus tubes require surgical intervention.

Phlegmasia alba dolens is similarly a mild form of bacteriæmia in which the pathological process consists of an infected femoral thrombophlebitis. The fever is of a low grade, and the location of the pain over the femoral region readily indicates the nature of the infection. My plan of treatment in these cases has been in the direction of nonintervention; no rubbing of ointments or liniments, no massage, no active movements. By keeping these patients quiet in bed, with the limb elevated until the fever has subsided and the pain has entirely disappeared, the disease usually runs its course in ten days. There is no objection to the use of an ice bag over the inflamed area and a flannel bandage rolled upward from the foot to the thigh during the period of active symptoms. By following this plan during a score of years I have never met an embolus as a result of the premature disturbance of the blood clot in the vein.

Group IV. *Fever due to general peritonitis.* Although clearly a variety of bacteriæmia and characterized by the worst kind of a prognosis, for clinical purposes we can group the cases with general peritonitis in a class by themselves. In the fulminating type of the disease, very soon after delivery, the abdomen begins to distend; general abdominal pain is complained of; vomiting and constipation become more and more marked; the facial expression (in spite of a clear mind) looks sunken, haggard, drawn, and anxious; the cheeks have a hectic flush; the tongue is brown and dry; the pulse—associated perhaps with a low grade of temperature and chills of varying severity—becomes at an early period small and rapid; and, often in the short period of several days, the patient is dead. The diagnosis is easy if the distended abdomen, small thready pulse, and facial expression has been once seen. Still, on several occasions, I have known intelligent practitioners to mistake a condition of intestinal paresis with exaggerated abdominal distention for peritoneal sepsis. Of course the absence of rigidity of the abdominal wall, the

absence of tenderness, the absence of fever and rapid pulse, should make the distinctive diagnosis perfectly simple, and a dose of castor oil or a high medicated enema containing oil of turpentine will equally rapidly cure the patient.

Real acute septic peritonitis presents the same appalling picture familiar to abdominal surgeons after severe infections. Authorities differ as to the management of these terrible cases. Unless recognized in the earliest stage I cannot see any benefit from hysterectomy. That surgical intervention offers some hope in certain cases can be implied from the statistics of Cyrille Jeannin, published a year ago. Of 121 cases of general puerperal peritonitis subjected to surgical treatment this author notes sixty recoveries and sixty-one deaths. He therefore advises operating every case of puerperal peritonitis "as soon as diagnosed." There can be no doubt that the finding of pus pockets, after laparotomy, offers the patient a chance for life, although I must record one death in a case in which I found several pus pockets between the coils of intestine. The presence of pus, however, is not always clear, so that intervention assumes necessarily the character of an exploratory operation. On the other hand, if the case is not *foudroyante* in type, but assumes a less virulent character, it is possible for such patients occasionally to get well without operation. I have met several examples of puerperal peritonitis which terminated in spontaneous recovery.

On the whole, given a positive diagnosis of puerperal peritonitis with the patient in a fair condition, I think that a laparotomy in proper hands offers her a better chance for her life than if nothing is done. As for the opium treatment—as recommended by the late Alonzo Clark—and which I was taught to push to the extreme, I believe it frequently pens up secretions and masks symptoms. I use it only in exceptional cases.

If a general peritonitis shows a tendency to rapidly subside under the use of ice to the abdomen it may be well to wait in the hope that the process will go on to complete recovery or that pus formations will become localized. I have thus on several occasions, in which peritoneal manifestations seemed to be quite violent at first, known pus to become sacculated in Douglas's cul de sac. In one case, after vaginal section behind the cervix, a considerable quantity of pus escaped, but the peritonitic manifestations continued, and the patient died. In another similar case I resorted to a vaginal hysterectomy, and the patient recovered. I recall one case seen many years ago in which a post partum inflated abdomen, with temperature reaching as high as 106° F., induced Dr. A. Jacobi, who saw the case in consultation, to suggest the possibility of intraperitoneal suppuration. Unable to secure the patient's consent to an operation she was treated by the liberal use of ice bags to the abdomen. She made a good recovery, has had several children since, but carries as a memento the extensive scar left from the sloughing of the abdominal wall which resulted from the too assiduous application of the ice bags.

In the preparation of this paper I have endeavored to sketch the outlines of the febrile condi-

tions following abortion and childbirth with few strokes of the pen. The elaborate descriptions of detail I have purposely left for the Meissonniers in our profession or the writers of cold textbooks. If the essay, brief as it is, can bring forth an instructive discussion, the purpose of my writing will be fully accomplished.

112 EAST SIXTY-FIRST STREET.

## VACCINATION IN THE FAR EAST.

BY CHARLES S. BRADDOCK, Ph. G., M. D.,  
Haddonfield, N. J.,

Former Chief Medical Inspector, Royal Siamese Government.

The history of all nations the world over, whether in tropical or polar regions, has been only a repetition of the same dismal tale, that is, the advent of the white man. He has not only brought civilization, but many serious ills in his train, both physically and morally. Among the diseases traveling in the train of civilization smallpox is one that easily leads in its terrible destruction of life and in blindness and disfigurement of the human countenance that it leaves in its wake.

The average man who lives at home, and does not have his attention particularly drawn to the matter, does not realize the terrible loss of life in the past, and which is still going on in remote parts of the world.

In the South Sea Islands, in the Far East, in China, Indo-China, Siam, the Malay Peninsula, Arabia, Persia, Africa, and many other parts of the world, the death roll in past epidemics has run into hundreds of thousands of people who, if they had had protection by vaccination, might have lived long lives of usefulness, not to speak of the thousands of blind and disfigured persons. It is no uncommon thing to see in some cities in the Far East six or eight totally blind persons being led in one line by a blind leader, each one with his hand on the shoulder of the one in front. Literally, as the Scriptures say, "Blind leaders of the blind."

In Siam up to recent years practically all of the new cases and the great death rate were among the children, for all of the older people had had the disease during successive epidemics.

In 1903 the death rate in Siam and its dependencies was 10,000, and this was only one epidemic. These epidemics have been recurring every few years. Dr. Peoples, a Presbyterian medical missionary in the province of Nan, one of the Laos provinces in the north of Siam, told me that in that province, which has now a population of 600,000 people, 100,000 had died of smallpox in the past thirty years. This is only a sample of what has been taking place all over the Far East with the exception of the British colonies, where vaccination has been pushed by the British government. In Indo-China the French government faces the situation that the population has decreased 50 per cent. since they first occupied the country, and efforts are now being made to vaccinate and instruct the people in sanitation by government medical men. In 1903 Dr. H. Adamson, inspector general of hospitals, and myself called the attention of the Siamese government to the terrible death rate in Siam from small-

pox and showed the great inroads it was making among the already sparse population of pure Siamese, who had also suffered so severely from cholera, malarial fever, and dysentery, and was to have bubonic plague added to their troubles. But smallpox caused more deaths than all of the other diseases together.

Prince Darmong, minister of the interior, a most able man, sent Dr. Adamson to Manila to study the American methods there of making vaccine at the United States Government Laboratory. On his return active efforts were made to make vaccine in Siam. The French were making fine vaccine at the Pasteur Institute at Saigon, but the vaccine spoiled very quickly in the tropical climate, and long before it could be used in the interior. The German and Japanese doctors in Siam had had a try at it, but, owing to climatic and other conditions, they met with absolute failure. Dr. Adamson and myself worked hard, the government giving us every facility that money could procure, a well fitted up bacteriological laboratory, etc. But it was nine months before we succeeded in making vaccine, nine long months of failure and disheartenment. But at last we succeeded and made good vaccine. We were both proud men when we exhibited to the Siamese officials a large number of children with well marked vaccine sores on their arms. All of the physicians in the Siamese service were put to work, and in two years we had vaccinated 400,000 people, mostly children, without a single death from tetanus. During this time Dr. Adamson and I inoculated and scraped every calf with our own hands, made all of the cultures and bacteriological examinations, and supervised every detail, as we had no one we could trust to do it. Dr. Paul G. Woolley, a most able and talented man, a graduate of Johns Hopkins University, came from Manila and took charge of the work finally, and he now fills the position I formerly held, that of chief medical inspector of the royal Siamese government.

It was only a few weeks after the first successful vaccine was made that we had a splendid opportunity to see what vaccination meant. Smallpox broke out in the town of Tatchin, situated at the mouth of the Tatchin River. In thirty days 145 children died of the disease, before we were notified of the outbreak. This meant about 500 cases, and we dispatched a fast steam launch with a number of vaccinators, and in a few days had vaccinated 4,000 people, absolutely stopping the epidemic at once, as there were no more cases after the period of incubation of those already infected was over, and even in these it modified the disease. Tatchin has never known smallpox since.

The Presbyterian missionaries in the north, in the Laos country, heard we were making vaccine, and at once sent for supplies. As one of them expressed it to me: "Doctor, I have gone through hell in years past in seeing my people dying by the score of smallpox and being helpless to stop it, and now we can stop it." Dr. McKean, of Chengmai, at once inoculated calves with the vaccine we sent him and started the work in the far north, and this year he has 250 vaccinators at work who will average a thousand or more vaccinations each, so that he alone

will probably vaccinate 250,000 this year. The work is going on from the Federated Malay States to the Indo-Chinese frontier and from Burma to Indo-China, so that in a short time smallpox will be absolutely a thing of the past in Siam.

The Chinese at once took advantage of the great demand for vaccination, and it was soon found that it was necessary for the government to issue an order allowing no one to vaccinate without a government permit, as we found that the Chinese doctors, in their anxiety to make money, vaccinated the people with bogus vaccine and were using condensed milk, gum resin from a tree, and pus from syphilitic ulcers as well as pus from smallpox ulcers. The great and unusual death rate among the children from smallpox was due to the fact that practically all the adults were the sufferers of previous epidemics and all had had the disease.

Dr. Peoples told me that in the epidemic of 1898 he traveled over a large stretch of country in the Laos province of Nan, and on investigation found that in that epidemic alone 75 per cent. of all the children under seven years of age had died over a great part of the province, and this in only one epidemic. This meant that, of 500 children in a village, 375 died of the disease.

One of the most heartrending things was to go into a village and have the dozens of totally blind children brought to you to see what could be done for them, all made blind by smallpox. The poor people had an idea that the Moh Luang, the king's doctor, would be able to give them back their sight.

To-day the great campaign is going on among millions of people, and over hundreds of thousands of miles of territory. Too much praise cannot be given to the work and selfdenying exertions of the missionaries, both medical and lay, who have gone out on tours and have vaccinated thousands and thousands of children in the past two years. The great extent of this work was shown by the official reports sent to me by Dr. Dunlap, Dr. McDaniel, and Dr. Walker, who vaccinated nearly 10,000 children in one season, and of Dr. McKean, of Chengmai, who vaccinated 17,500 in one season. They are all attached to the Presbyterian mission.

The Siamese government fully appreciate the work the missionaries have done, and the government is cooperating with the missionaries. Personally I am proud of the fact that Dr. H. Adamson and myself made the first vaccine ever made in the kingdom of Siam, and started the great work which is now going on to such an enormous extent.

After coming back to America after years of sojourn in the Far East, I have been utterly astonished and surprised to read articles in papers denying the protection of vaccination against smallpox, and learning of so much opposition from parents to have their children vaccinated, also of the activity of antivaccinationists. I wish I could show some of these people the results of vaccination in the Far East, in Siam and the Malay Peninsula. It might shame some of the ultracivilized to see the gratitude shown by a poor heathen mother when she knows her children will not lose their lives or be blinded by this disease.

In conclusion, it might be interesting to tell what

the Siamese believe is the origin of the disease. I quote a translation of a Siamese medical book in my possession, translated for me by Dr. Dunlap:

"There is a great giant that lives in the sky and who has seventy-six sons and daughters; each one of these is a variety of (Fidat) smallpox. When the giant sends one of them to earth and he visits the individual, that individual has that variety of smallpox, one of the seventy-six the Siamese divide the disease into."

The book gives no remedy for the disease, but simply diagnoses the case, and tells how long you will live, all of which varies from three days to three weeks, according to the location of the eruption on the body.

#### DISEASES OF THE BREATHING APPARATUS WHICH AFFECT THE BREATH.

*The Breath as an Aid in the Diagnosis of These and Other Diseases.*

By F. E. KLOTZ, M. D.,  
Lanark, Canada.

Just as we draw inferences from the odor of discharges and of pathological tissues in other parts of the body, let us try to improve on our diagnosis of affections of the breathing apparatus by always taking into consideration the odor carried forth on the expired air. In addition let us not fail to note that certain constitutional diseases, septic processes and drugs, affect the breath markedly.

I shall enumerate first, the affections of the nose, throat, mouth, larynx, bronchi, and lungs, which may be the cause of an abnormal breath, and where possible, describe in short the character of the odor:

First.—Chronic hypertrophic catarrh of the nose and nasopharynx causes a breath warmer than normal, without necessarily any other change; at times it has a heaviness without any distinct odor; then again it may have an odor which is slightly disagreeable, but never markedly so.

Second.—Ethnoidal, frontal, sphenoidal, and antrum diseases cause hypertrophic conditions, so that we have the hypertrophic breath plus that due to the formation of mucus, which latter gives forth ordinarily a heavy, sweetish, somewhat disagreeable odor. Where an antrum is involved the odor is sometimes highly offensive, dense, and penetrating.

Third.—Fibromata of the nose and nasopharynx produce no odor of themselves. Any odor depends on mucus formation.

Fourth.—Mucous polypi, no odor of themselves.

Fifth.—Ozena, well termed *Stinknase* in German, for this condition produces perhaps the rotteness—to use a vulgar, although in this case most applicable, word—of all breaths; it is a conglomerate odor of animal decomposition, fetid, arid, and nauseating, and can be detected many feet from the patient; once experienced it is never to be forgotten. The patient with this malady often leads a sad, miserable, and isolated life.

Sixth.—Syphilis of the nose: Gummata produce an odor only when their surfaces become broken down; the odor then depends on the amount of discharge from the deposit on the ulcer surface; gener-

ally only slightly offensive, heavy but rarely foetid. Mucous plaques in the nose, unless large, hardly affect the breath; this is not the case in the mouth.

Seventh.—Lupoid ulcerations: No distinctive odor, though it may cause one to suspect the chronic formation of pus.

Eighth.—Tubal discharge of chronic otitis media may cause a sharp, penetrating odor almost like Roquefort cheese, and easily detected when necrosis of bone is taking place in the middle ear. This odor is periodical in character, due to the varying patency of the tube and position of the head.

Ninth.—Tuberculous ulcerations which affect the palate and nasopharynx more frequently than the nasal cavities proper, produce an offensive breath, which may be described as heavy, bitterish, and putrescent.

Ten.—Internal lacerations due to fractures produce a temporary heavy sweetish "recent pus" odor; the blood in the cavities of the nose during the first few days gives the breath an additional quality faintly like burning sulphur.

Eleven.—Atrophy of the mucosa of the nasal cavities produces a light, slightly foetid breath, not suffocating, if I may use the term, as that of many other conditions; moreover, there may be no odor whatever.

Twelve.—Foreign bodies in the nose may cause a slight mucopus odor or a highly offensive, steamy, heavy odor; it all depends on the nature of the foreign body and the length of time elapsed since its introduction.

Breath as affected by mouth conditions where the mouth becomes the passage of expired air.

One.—Cancrum oris.—This condition, like many others of the mouth cavity, is productive of a hypersecretion of mucus and saliva; in consequence, the breath is superheated, slightly heavy, and steamy. In addition, we may get the first hint of gastric dyspepsia.

Two.—Pharyngitis sicca produces no distinctive odor or one somewhat resembling that of the atrophic nasal condition.

Three.—Chronic tonsilitis, with constant and copious secretion of cheesy material, produces a heavy, cheeselike (limburger), sweetish, offensive odor, which is fairly easy of diagnosis. The still more chronic condition in which the cheesy material is retained and becomes more or less solidified, occasionally forming calculi, is productive of a distinctive breath, which is present only when the firm retention masses come to the surface; it may be described as stinking and penetrating, an odor not far removed from that of the decayed nerve of a tooth. Adenoids, sometimes, when firm and much enlarged, give nasal and mouth breathing the characteristics of chronic tonsilitis, as described.

Four.—Tonsil, pillar, and pharyngeal diphtheria produce a foul, heavy, superheated and suffocating odor, dry or steamy, according to amount of fever, stage of disease, and amount of mouth and bronchial secretion.

Five.—Tuberculous ulceration, especially of the tonsil, is always offensive, and may be very sharp and penetrating, even though no bone is involved; the odor may affect the air of the whole room.

Six.—Soor, or mudget, if extensive, has the odor

of a rapidly progressive ulceration with necrosis; heavy, though not as highly offensive as the more chronic tuberculous lesions.

Seven.—Ulcerated gums produce a heavy, offensive breath, with the tainted egg smell added, and not detected except when very close to patient.

Eight.—Decayed teeth, in which a large portion of the central pulp is exposed, give to the breath a light, penetrating, often bitter, odor, though rarely as offensive as necrosed bone in other parts of the head. It may resemble the odor of decayed vegetables, apples and onions, or of decayed Brazil nuts.

Nine.—Mouth breath following the extraction of teeth resembles that of diphtheria and tuberculous pulmonary cavities, inasmuch as it will pollute the atmosphere of a whole room if patient sleeps with the mouth open. It may be described as extremely foul and nauseating, not unlike the smell of very rotten eggs.

Ten.—Lupus, until ulceration takes place, has no effect on the breath, differing in this respect from the warty tuberculous excrescences sometimes found in the mouth cavity.

Eleven.—Syphilitic patches are productive of a heavy, steamy breath, which may or may not be offensive. The odor of gummatus ulcerations has nothing distinctive, the offensiveness, when present, being due to the amount of deposit taking place on the ulcer base.

Twelve.—Salivary and mucous inactivity cause a dry, hot breath, with bitter sweet characteristics.

Thirteen.—A furred tongue produces a heavy odor of decomposing epithelium, which may be modified by decomposed food, which so readily mingles with dead epithelium.

Fourteen.—Hypersecretion of saliva, as in acute tonsillitis, produces a heavy, steamy, slightly offensive breath, only detected when close to patient's mouth. Potassium iodide, producing hypersecretion also, gives the breath at times a certain sharpness difficult of description.

Fifteen.—After a dietary of strong foods, such as onions, radishes, and salt fish, the mouth breath may retain the flavor of these for many hours.

Sixteen.—Pharyngitis hypertrophica has nothing distinctive.

Seventeen.—The use of tobacco, as pipe or cigars, produces the well known smokers' breath.

Eighteen.—An alcoholic drink will affect the mouth breath for a short period; the same taken in large quantities will cause an offensive breath having the flavor of the liquor taken, but not till some time after the liquor has been ingested, and then it is the alcoholic pulmonary breath which obtains; this often savors of undigested food, and has a bitterish quality.

The breath as affected by larynx conditions:

One.—Lupus in nodular form does not affect breath, even though obstruction is imminent. Lupus ulcers of the larynx are rare and hardly worth discussing.

Two.—Syphilis.—Only when cartilage or bone is affected do the ulcerated surfaces give off an offensive odor.

Three.—Tuberculosis of the interarytenoid space often begin as a papulematous growth, more or less

fissured. This condition produces a bitterish odor, though not penetrating, nor really offensive; if ulceration takes place and extends to deeper parts, the breath becomes quite evil smelling and penetrating, and much more offensive than an ulcerated lupus or syphiloma.

Four.—Diphtheritis of the larynx.—More offensive than the same condition on the tonsils, and very apparent even when the mouth is closed.

Five.—Laryngitis sicca, singly or associated with pachydermia laryngis, produces a "thin," acrid, bitterish breath of a most penetrating character. In persons past thirty this breath may be powerful enough to permeate every room in a small dwelling. Although different persons, suffering from this condition, may not have similar breaths, yet the breaths of all have like characteristics, so that the cases can generally be easily diagnosed without the laryngoscope.

Six.—Foreign bodies in the larynx produce a more or less offensive breath, varying according to amount of damage and length of time the foreign body has been retained; the same applies to foreign body in bronchus, and I may state that the breath in one case I saw was highly putrid, though it resembled that accompanying nasal foreign bodies.

Seven.—Malignant diseases of larynx.—One of the two cases I met with had a very acrid, bitterish breath.

Eight.—Cigarette smoker's breath.—This can be detected when three or four feet from the "fiend"; the latter term I apply to one who consumes at least twenty cigarettes daily, constantly inhaling the smoke till his larynx and trachea are stained yellow, and a chronic, generally desquamating, catarrh is set up. The breath of the fiend is then heavy, foul, sweetish, and nauseating, with only a trace of real tobacco odor to it. The constant smoking of pipe or cigars produces a characteristic and bad breath, but it is mild in its offensiveness compared to that of the cigarette fiend, in whom the breath acquires its foulness in the trachea, larynx, and lungs.

Among the diseases of the bronchi and lungs which affect the breath I may mention:

One, chronic purulent bronchitis; two, tuberculosis of the lungs; three, abscess of the lungs; four, gummata of the lungs; five, asthma in advanced stages; six, pneumonia—later stage; seven, malignant diseases of lungs (rare); eight, anthracosis (rare); nine, actinomycosis (rare); and, ten, emphysema.

Of these, abscess and tuberculous cavities give forth the most evil smelling breaths. In the former it often resembles the odor of moist putrid flesh, with an acridness added. Tuberculous cavities filled with glairy pus give the breath, when observed close to the patient, a most penetrating, nauseating, foetid odor, the factor having some of the characteristics of coal gas. Chronic purulent bronchitis often gives the breath a sulphuretted hydrogen odor. This peculiarity is sometimes present in phthisis. Asthma breath is frequently sourish, but may have a variety of odors; rarely is it offensive unless complicated by laryngeal or nasal conditions. Miliary tuberculosis of the lungs does not impart any odor to breath except that it might be designated a "raw

erish" breath. The breath of the "lunger" in the early stage of the disease is quite distinctive, though it would be almost impossible to describe it.

I shall not attempt to describe the other pulmonary breaths, as they are subject to much variation.

Breath as affected by constitutional diseases and drugs:

One.—Constipation and copræmia are probably the commonest causes of bad breath in otherwise healthy subjects; in the worst cases one would imagine the lungs were full of feces, so much does the breath resemble fecal excretions.

Two.—Diabetes is credited with affecting the expired air, but I cannot speak from experience.

Three.—Advanced chronic interstitial nephritis and uremia give to the breath a urine flavor plus that of eggs turning bad.

Four.—Febrile conditions produce a hot, dry breath, bringing to mind pent up excreta and the value of calomel.

Five.—Septic processes are productive of a vile, foul breath, often quite characteristic.

Six.—Cachexias are often accompanied by a breath odor of something dead.

Seven.—Chronic dyspepsia is frequently accompanied by a heavy, sourish breath, and one in which the odor of undigested food is to be detected.

Of the drugs and poisons which affect the breath I may mention mercury, arsenic, opium, alcohol, iodides, bromides, chloral, oil of turpentine, phosphorus, hydrocyanic acid, carbolic acid, creosote, chloroform, ether, iron, mineral acids, oxalic acid, nitrobenzene, peppermint, and camphor.

In conclusion, I wish to refer to the rarity with which reference is made, in clinical work, to the character and quality of the patient's breath. The nature of the breath has frequently led me to suspect and discover conditions which, ordinarily, would have been fairly difficult of diagnosis, and in many conditions we may fairly judge of the severity of the disease by the intensity of the breath odor.

## THE TREATMENT OF "COLD IN THE HEAD."

By HENRY H. PELTON, M. A., M. D.,

New York,

Medical Clinic, Presbyterian Hospital Dispensary; Instructor in Medicine, New York Postgraduate Medical School.

Cold in the head, while not in itself a serious ailment, is a most uncomfortable one and one which may lead to more or less untoward complications, therefore it would seem that any means which lead toward the mitigation of the discomfort and the prevention of the possible complications are quite worthy of trial.

With regard to prophylaxis it is important that all intranasal and pharyngeal abnormalities, particularly adenoid growths and hypertrophied tonsils, should receive appropriate treatment; this, in the case of the two conditions mentioned, consists in nothing less than thorough removal. Further prevention of cold in the head may be secured by giving attention to the hygiene of the nose and throat,

by wearing proper clothing, and by avoidance of exposure in so far as may be possible. The nose and throat should receive cleansing douches or sprays at least once daily, for these situations, particularly in cities where dust and smoke contaminate the atmosphere to an excessive degree, gather foreign substances teeming with microorganisms which cannot but be prejudicial to the maintenance of their mucous linings in a healthy condition. The only drawback to the use of sprays and douches is the possibility of transferring, by these means, infection to the middle ear through the Eustachian tube, but the probability of this untoward occurrence may be, in great measure, avoided by refraining from blowing the nose for at least five minutes after the use of the intranasal application, and then performing this act only in the most gentle manner. A useful spray or douche for the purpose named is the liquor antisepticus of the pharmacopœia diluted 1 part to 6 parts of water, or a mixture consisting of boric acid, 5 grains, sodium borate, 5 grains, phenol,  $\frac{1}{2}$  grain, to the ounce of water.

It is often difficult to be certain, before the onset of distinct symptoms, that one has "caught cold," but if there is suspicion that such is the case the affection may sometimes be aborted by the administration of  $\frac{1}{4}$  grain of calomel every 20 or 30 minutes until six doses have been given. This is to be followed on the succeeding morning by a saline purge such as the effervescent solution of magnesium citrate, epsom salts, or a glass of one of the saline waters, such as Hunyadi János or Apenta. Following the calomel the patient should take 10 grains of compound ipecac powder and a hot drink consisting of a half ounce of whiskey and about eight ounces of water; to this lemon juice and sugar may be added if desired. In the event of the patient's objection to alcohol a glass of hot lemonade will often have the same effect. The patient should now retire and cover himself warmly in order to induce free diaphoresis. The above procedure may entirely ward off the threatened cold.

When the affection has fastened itself upon the patient the nasal cavity should receive frequent irrigations of warm (100° F.) normal 0.9 per cent. solution of sodium chloride. Each irrigation should consist of at least a quart of the solution and is best given from a fountain syringe, the reservoir of which is held at an elevation of a foot or two above the patient's head. To the end of the tube a glass nozzle should be fitted and the latter should be applied to each nostril in turn, the solution being allowed to flow in at the one and out at the other while the patient breathes through the mouth and holds his head forward over the wash bowl or bath tub. The solution moistens the dry and inflamed mucous lining of the nasal fossæ in the early stages of the cold and washes away the accumulated mucus in the later stages, leaving the nasal mucosa clean to be acted upon by a spray of 10 per cent. aqueous solution of silver vitellin; this has a distinct germicidal, astringent and curative effect upon the inflammation. Following these procedures a spray consisting of menthol 1 grain, eucalyptol 8 minims, benzoinol 1 drachm to the ounce of liquid petrolatum will soothe the intranasal irritation and

cause a certain amount of contraction of the turgid tissues. The sprays mentioned above should be used upon the pharynx as well as in the nose. Oily sprays containing adrenalin chloride are also useful to lessen the congestion, but appear to have no especial advantage over the mentholated spray and possess the disadvantage of being very expensive. If involvement of the frontal sinuses is present, as evidenced by pain and a feeling of fullness above the bridge of the nose and over the eyes, this may be relieved by the administration of a powder consisting of salipyrine 10 grains, and quinine sulphate 1 grain; this may be taken every 3 or 4 hours, and if there is any tendency to cardiac weakness a grain of citrated caffeine should be added to each dose.

The so called rhinitis tablet, consisting of belladonna extract  $\frac{1}{8}$  grain, quinine sulphate  $\frac{1}{2}$  grain, and camphor  $\frac{1}{2}$  grain, has never proved itself of any especial value in the hands of the writer, but it may be prescribed if desired or a tablet or capsule containing equinine  $\frac{1}{2}$  grain, hyoscyamus extract  $\frac{1}{4}$  grain, and monobromated camphor 1 grain, may be substituted for it.

In many patients a cold in the head is followed by a bronchitis of varying severity; in such the writer has been able to prevent this sequela by the administration of pure beechwood creosote in doses of 5 drops, taken in a spoonful of milk after each meal; this should be begun at the inception of the nasal inflammation in these patients and should be continued for several days after its subsidence. The appearance of any gastric disturbance or of darkening of the urine is a signal for stopping the creosote, which may be begun again in a day or two in smaller dosage. The substitution of creosote carbonate in 10 drop doses for creosote will obviate all possibility of toxic symptoms, but the latter drug has the disadvantage of being very expensive.

The complication of eustachian tube inflammation necessitates the employment of the Politzer bag for the purpose of inflation, and possibly eustachian catheterization may become necessary. Should the inflammation extend to the middle ear, as is often the case in children, especially in those with adenoid growths and enlarged tonsils, the drum membrane should be punctured at the least indication of bulging of this structure. This operation is a simple one to the skilled hand, and the provision of free drainage for the tympanic cavity may ward off mastoid involvement with all the dangerous complications which may follow. Following the paracentesis the canal of the ear should be loosely packed with gauze, which should be renewed as soon as it becomes saturated with the discharge, and free irrigation with warm  $\frac{1}{2}$  saturated aqueous solution of boric acid should be employed daily. The intervals of irrigation may be lengthened as the discharge becomes less, and after a few days two or three minims of a 20 per cent. aqueous solution of silver sulphate dropped into the canal may hasten the cure.

The doses given in this paper are for adults. In prescribing for children they should be lessened in accordance with the age of the patient.

## THE TEACHING OF DERMATOLOGY IN MEDICAL SCHOOLS.

By CHARLES A. KINCH, M. D.,

New York,

Dermatologist to New York City Children's Hospitals and Schools;  
Clinical Assistant to the New York Skin and Cancer  
Hospital, New York.

Is a knowledge of the principal facts of dermatology and syphilology necessary to the general practitioner?

"It will be conceded that it is essential that the physician should be able to diagnose the exanthemata, to protect the public by advising quarantine, and to avoid panic; yet to do this it is necessary to distinguish from them the various forms of erythema, dermatitis, and syphilis. The gravity and often unsuspected presence of the latter makes it of the utmost importance to the individual, to the family, and to the public, that a correct diagnosis be made and appropriate treatment be carried out."

(The Need for Higher Requirements in Examinations in Dermatology and Syphilology by Medical Colleges and Examining Boards, by William F. Breaky, M. D., Ann Arbor, Mich. Read before the Sixth International Dermatological Congress, September 9 to 14, 1907.)

Many affections of the skin are also contagious, notably scabies, ringworm, and contagious impetigo. When these gain headway in a group of closely connected families or an institution, energetic and persistent treatment is required to eradicate them.
